The results of a univariate analysis of the entire 73 year sample are presented in Table 2 and in Figure 1. Table 2 shows the sample mean, variance, standard deviation, and other attributes of the data set. Figure 1 shows the histogram of the frequency of different levels of delivery. Figure 1 is most interesting in that it shows the sample to comprise two distinct domains, one constituting most of the sample showing the deliveries for what can be called normal or wet years and the other constituting the collection of dry years. There is a region in between these two domains, between 2100 and 2540 taf (thousands of acre-feet) for which there are no calculated deliveries. According to Table 2 the average of this 73 sample is 2961.8 taf which is not within the main mode of the normal/wet year data. Thus the sample average is not representative of any particular attribute of this bi-modal distribution.

Statistical tests were performed to determine whether or not these two subsets of the data, normal/wet and dry, can be considered to come from the same population. The answer is most definitely not. To perform this test the 73 year period was separated into the two nominal populations for which means and variances were calculated and tested for significant differences using a standardized "t-test." The probability that such a bi-modal distribution could be drawn from one population by chance is infinitesimally small. Accordingly, no confident statements can be made about probabilities of delivery by assuming the sample to come from one population. **As a consequence, the reported average and the use of the frequency charts in DWR's report are without statistical validity. No probabilistic statement of delivery reliability can be derived solely from the frequency charts presented in the report.**

If we examine the record of calculated deliveries shown in Table 1, it is quite evident that there are extensive dry periods, the worst of which is shown as that from 1929 through 1934. In fact, this is referred to as the historic worst drought. The drought most recently experienced, 1987 through 1992, also 6 years in duration, was almost as severe from a hydrologic standpoint. Each of these two periods has embedded one decent year that if it were not part of the drought episode would not be so significant. The fact that it is embedded is important because following a dry year or dry sequence the embedded year is not good enough to refill the two big SWP reservoirs, Oroville and San Luis, for the following year. Hence it is part of the drought sequence. (It would have been helpful to understanding SWP operations if the calculated record showed the end of water year storage levels for these two reservoirs.)

-14-

Further analyses were undertaken treating the two domains as independent populations. Because the dry year set comprises both the dry sequences of drought and several individual dry years sprinkled throughout the record, we have focused the dry year analyses on the drought periods. The two periods are combined into one population for analysis since their means and variances are reasonably consistent. However, we did exclude the beginning year, 1987, for the second period as it was not embedded in the sequence and could easily be classified as a fair to good year. Thus, we ended with a sample of 11 years, 6 years between 1929 and 1934 and 5 years between 1988 and 1992. The data set is shown in Table 3 and the resulting statistics are shown in Table 4.

Table 4 shows an average delivery of 1545 taf and a standard deviation of 678 taf. If the year 1987 were included the average would increase to approximately 1657 taf with not much change in the standard deviation. If the two embedded decent years, 1930 and 1989, are eliminated from the sample the average is decreased to 1267 taf with a standard deviation of 302 taf. These changes suggest that judged as separate occurrences these two years may not be statistically representative of the dry population. However, we will assume that the results shown in Table 4 are representative of the expectation for drought periods.

Lastly, we analyze the population for the normal/wet periods, a record of 58 years, not all in sequence. The years 1930 and 1987 were included in this sample and the individual dry years not part of either of the extended drought periods were excluded. Table 5 presents the data set used in the analysis and Table 6 shows the calculated statistics. Figure 2 shows the frequency histogram for this data set which clearly depicts a central maximum but still with some skewness. (Skewness is a term used to identify distributions that are not symmetric, that is distributions whose sample mean and median are significantly different.) Table 6 shows an average delivery of 3364 taf with a standard deviation of 325 taf. This then represents what is typical of periods of non-drought, an average that is about 81% of the full Table A value of delivery. The standard deviation represents 9.66% of the average delivery, showing a very consistent delivery for normal and wet periods.

How much delivery can we rely on?

As we stated before, what each contractor can rely on depends on the circumstances of his other sources of supply. However, we now have some valid statistical analyses upon which to base the level of delivery that can be relied on for specific circumstances.

First, we note that for any contractor without significant storage availability, the reliable level of delivery is dictated almost solely by drought conditions. If a particular contractor had no other supply to tap and wanted to pick a confident level of supply from the SWP, he would have to select from among the lowest individual years on record which could be as low as 804 taf, or 19.5% of the full Table A value. However, we assume that most SWP contractors have other sources available with which to operate conjunctively with SWP deliveries and the appropriate level of delivery would be the average value during a drought episode, approximately 38% of the full Table A value. If the average level is to be relied on, the other sources must make up the variation within the drought period. In other words, SWP deliveries would have to be taken at the available level shown in the CALSIM II output and the other sources of supply available to the contractor would have to made dependent on the SWP deliveries. This might cause a rearrangement of priorities of when all the other local sources are brought in to play in a given year. Ordinarily, local purveyors operate on a least cost basis meaning that sources are used in the order of increasing marginal cost. Since SWP marginal costs are likely in some instances to be greater than some local sources, the requirement to use SWP as available may require it to supersede the priority of some local sources in order that the notion of a reliable average delivery is indeed fact. This switch in priorities would entail some cost increases depending on the differences in marginal costs.

If a contractor has significant storage available, he may be able to store some wet year deliveries to be held in reserve for drought periods thereby increasing his reliance on SWP during droughts. The normal/wet period deliveries at an average of 81% could be relied on with high confidence (95%) at the average minus 1.6 times the standard deviation. This 95% confidence level would then be 69% of the full Table A value. In other words, such a contractor could state with high confidence that in normal or wet periods he can rely on 69% of full Table A deliveries with the strong likelihood that in many years he could receive more if it can be utilized. Whether or not it can be utilized depends again on his willingness to reorder the priorities of use of all his sources with the expectation that such a reordering will increase overall costs of supply slightly.

Even if a highly confident 69% can be relied on for normal and wet periods, that leaves the question of what to do in drought periods. Clearly, there will be sufficient excess delivery from all the years greater than 69% that can be stored for drought use, but the level depends critically on the magnitude of storage. If it was desired to bring the drought level of SWP use up to the normal/wet year reliable level, 69%, enough storage would have to provided to make up the 31% of the Table A value represented by the difference between the drought period average and the 69% level. Thus, 31% per year for 6 years (the worst drought on record) of the contractor's Table A value would have to be kept in storage. This amounts to 1.86 times the contractor's Table A amount and there would have to be some allowance for storage losses, such that 2.5 times would be reasonable. Thus, for such a contractor to rely on 69% deliveries from the SWP through wet and dry periods, he would have to have available in magnitude 2.5 times or so his Table A amount dedicated to SWP storage. For the entire SWP contract in the aggregate, this amounts to 2.5 times 4130 taf or approximately 10 million acre-feet. This would have to be storage south of the Delta since the CALSIM already takes maximum advantage of the pumping capability of the project.

Clearly, the right level of reliance on SWP deliveries depends on the circumstances for each contractor. Because it is highly unlikely that the storage requirement to reach 69% can be achieved for many contractors, especially the larger ones, a level lower than 69% will have to be calculated. Each contractor will have to do so independently.

Some Conclusions

We have shown that the values for SWP delivery reliability presented in DWR's report are not statistically valid. The level of 76%, which represents the average calculated by CALSIM over the 73 year record, cannot be assumed without question by any contractor and it is highly unlikely that such a level can be substantiated by any contractor. The DWR report does acknowledge that during the two 6 year drought periods, a level of only 39% to 40% can be relied on. However, that is the average for a six year drought period and still requires each contractor to analyze how he will adjust his priorities of use among all his sources. Even levels in wet years may stretch an individual contractor's capabilities given that there are capacity constraints in the aqueducts that prevent taking full deliveries in low demand months without significant means for equalizing storage between low and high demand periods. In all of this it is important to recognize that seizing on an "average" value implies that deliveries will follow the project's capability to pump the amounts calculated in the CALSIM II model. This means that in wet years the water must be taken and either used or stored if the average is to have any meaning. The DWR report is not candid on this aspect.

RE: 41,000 Acre Foot Transfer SCH# 1998041127

Dear Ms. Cotton,

It has come to our attention the Castaic Lake Water Agency is possibly planning to affect a position on the above captioned matter which, in our opinion, will gravely impact the Monterey Agreement EIR process. 99

We also wish to comment that we see a direct conflict of interest and possible injustice to the public and interference with the CEQA process by your agency's spearheading any effort to circumvent, delay, interfere, or otherwise impede the more appropriate participation of the Department of Water Resources, the agency we believe entitled to administrate on behalf of the general public of the State of California in this matter.

We, the below listed voters and community members raise our voices in writing in complete objection to any and all interference by the Castaic Lake Water Agency and formally request the immediate withdrawal of any and all past, present or future water transfer documents until the EIR is complete. Furthermore, we wish to be added to the list of mailings for any matters regarding this subject.

Thanking you in advance for acknowledging our request, we remain,

Sincerely,

Arnold Swan (et al)

Mr. & Mrs. Arnold D. Swan
Mr. & Mrs. Darrel Wildman
Mrs. Suzanne Spahn

Re: 41,000 AF Transfer of water from farmland to Santa Clarita, Northern LA County for urban expansion SCH#19908041127

Dear Ms Cotton:

Water transfers are a statewide issue that induce growth and reduce water for farming. Therefore I believe that your agency is the wrong lead agency for this project; I believe the correct lead agency is the Department of Water Resources, which is both indicated and qualified under state law to address statewide impacts. DWR will also notify all interested parties to the extent of their knowledge. **100**

If such a major transfer is allowed to proceed under the lead agency status of a small regional water agency, it will set a precedent that will affect many major water decisions throughout the state of California. I believe it is imperative that such a major change in state policy receive full environmental review and comments from all affected parties. I therefore request that this project be re-noticed by the Dept. of Water Resources acting as lead agency as a project of statewide concern so that all impacts may be disclosed and properly addressed.

Sincerely,

Jim Churchill, Owner

Re: Comment on Draft EIR for 41,000 acre-foot water transfer (State Clearinghouse #1998041127)

Dear Ms. Cotton:

On behalf of California Water Impact Network and Friends of the Santa Clara River, we wish to incorporate by reference the comments submitted on the above DEIR by the Sierra Club. We wish to emphasize, in particular, that Castaic Lake Water Agency is not the correct "lead agency" for this project under the California Environmental Quality Act. As the Third District Court of Appeal made clear in *Planning and Conservation League v. Department of Water Resources*, 83 Cal.App.4th 892, 920 (2000), "DWR, with its expertise on the statewide impacts of water transfers," is the proper lead agency under CEQA for decisions regarding transfers of State Water Project water between SWP water contractors. **101**

We also wish to incorporate by reference our Opening Trial Memorandum (filed August 21, 2003) and Reply Trial Brief (filed May 3, 2004) in the matter *California Water Network and Friends of the Santa Clara River v. Castaic Lake Water Agency*, Ventura Superior Court No. 215327. These memoranda point out the importance of recognizing DWR's lead agency status regarding transfers of State Water Project water.

Thank you for considering our comments on this important matter.

Very truly yours,

Stephan C. Volker

Stephan C. Volker
Attorney for California Water Impact Network and Friends of the Santa Clara River

SCV:taf

Castaic Lake Water Agency Meeting,)
July 28th, 2004.)
)

Meeting of Castaic Lake Water Agency, Public Comment Section, at 27234 Bouquet Canyon Road, Santa Clarita, California, Public Comment Section commencing at 7:12 p.m., Wednesday, July 28, 2004, before Lisa DiGiovanni, RPR, Certified Shorthand Reporter No. 11969.

I N D E X

ATTACHMENTS FOR IDENTIFICATION

1 2-page Letter to Marylou Cotton from Dana Wisehart from United Water Conservation District dated July 26, 2004

2 1-page Letter to Dan Masnada from Ray Pearl and Terra Donion from BIA dated July 28, 2004

SANTA CLARITA, CALIFORNIA

WEDNESDAY, JULY 28, 2004; 7:12 P.M.

MR. KAVOUNAS: Next item on our agenda is Item 3.1, a public hearing of the draft EIR for the Agency's supplemental water transfer of 41,000 acre-feet of State Water Project Table A amount.

The purpose of this hearing is to give the public an additional opportunity to comment on this project and its environmental impacts for consideration by the board. As you will be advised by the staff and the presentation before the hearing, there will be further board proceedings on this draft EIR in the future.

The primary purpose of tonight's hearing is to give the public time to make comments on the draft EIR. The board and staff are not required to ask questions nor make comments or responses to the public's comments.

There will be time for the board's questions, comments and responses in future proceedings. The staff will prepare written responses to comments for the board's review and approval after the comment period ends. I will now turn the item over to Marylou Cotton, the Agency's water resources manager.

Marylou.

MS. COTTON: Good evening, everyone. Thanks for coming. We have a team of people that are going to be making the presentations tonight on the EIR and setting up the public hearing process. We'll be having our general counsel, Russ Behrens, as one of the speakers. From SAIC, which is the Agency's environmental consultant, we'll have Rob Thomson, who is program manager for the EIR and Lorraine Woodman who's the EIR project manager, and Lorraine will be doing the bulk of the speaking tonight and then there will be me. I have a couple items to cover.

But next I'll turn it over to Russ.

MR. BEHRENS: Thank you, Marylou. I'm just going to give you a little background. As you recall, the previous EIR on the 41,000 acre-foot transfer was certified in 1999. And because that EIR mentioned and related to the Monterey EIR, the court held that because the PCL decision required the Monterey EIR to be decertified, the appellate court on our case held that since we were deemed to have tiered off that EIR, we had to decertify our EIR as well, even though the court stated in some dictum in the case that and all other respects our EIR was appropriate.

Then after we finished that process on remand, there was a request by the plaintiffs in the case to enjoin us from utilizing in any way the 41,000 acre-foot transfer contracts. And the court, Judge Yaffie, refused to enjoin our use of the 41,000 contracts, but reserved jurisdiction to determine whether or not in the future we were using the 41,000 acre-foot contracts for any improper purpose.

No action was ever filed in front of Judge Yaffie in that regard, but the plaintiffs filed an appeal of Judge Yaffie's order on remand, and it went up to the appellate court and, again, the appellate court refused to enjoin the use by the Agency of the 41,000 acre-foot transfer. And this was further confirmed recently in the Network Groundwater Storage Project because one of the ways we do use our 41,000 acre-foot contract is we get an allocation of water from the State Water Project, which if we don't need, we have the opportunity to store in outside basins outside the agency such as the semitropic.

That case was challenged by Network and

recently the Superior Court of Ventura County refused to enjoin that project and held that it was properly processed with a negative declaration.

So we are now in the process of completing our current EIR. It's being prepared in accordance with all the requirements of law and the court judgments.

I'll now turn it over to Lorraine -- or to Rob to talk about how we process this EIR.

MR. THOMSON: Good evening. This is just a very quick reminder of the CEQA process, where we've been and where we are and where we're going.

Starting up here in the upper left, we -- this agency, following the decertification order, developed a new project description following the directives of the court and developed a new project, published a notice of preparation and a new initial study, and did that in January of 2003, held the 30-day requisite comment period, received comments. Both the NOP and those comments are in Appendix A of the document in total.

Those provided us the scope of the document and provided us with some direction towards the approach. From that we prepared the technical analyses and the administrative drafts of this document, very complex with multiple iterations and baselines and so on.

After extensive review and analysis, we have now in front of you the draft EIR, and that comment period opened on June 17th. Because of the complexity of this document, the agency determined that it should have a 60-day review period rather than the statutorily mandated 45 days. Comment period will close on August 16th.

From there we'll take the comments that are received and provide responses and develop a final, which then your board will consider, and should you find it to be adequate and certify it and move forward.

With that, I think we go to Lorraine to do a quick review of the EIR itself.

MS. WOODMAN: Good evening.

MR. KAVOUNAS: Good evening.

MS. WOODMAN: The purpose of the project evaluated in this EIR is to meet the existing water demand in the CLWA service area and a portion of future water demand from anticipated growth. This would be accomplished by transferring an existing 41,000 acre-feet of State Water Project Table A amount to CLWA.

The term Table A amount refers to the annual maximum amount of water the State Water Project contractor can request. The Table A amount would be transferred to CLWA from the Kern County Water Agency and its member unit, the Wheeler Ridge-Maricopa Water Storage District.

Project water would be delivered to CLWA through existing State Water Project facilities located between the southern delta and Castaic Lake. No new construction would be required as a result of this project.

This EIR is being prepared by CLWA, which as the lead agency will evaluate and, if appropriate, exercise its discretion to certify the EIR, make findings, and approve the project.

CLWA has assumed the role of lead agency for a number of reasons: The water would be used by CLWA in its service area; it is the major project proponent; it is leading State Water Project water supply contract amendment efforts; it has the expertise to implement the project; and the project impacts only involve a limited geographic area, not the entire state.

Three responsible agencies have been identified. These are agencies other than the lead agency that have the responsibility for carrying out or approving a project.

The responsible agencies for this EIR are the Department of Water Resources, because State Water Project water and facilities are involved, and the Kern County Water Agency and the Wheeler Ridge-Maricopa Water Storage District, because their Table A amount would be transferred to CLWA.

In compliance with CEQA requirements, these agencies have been active participants in preparing the EIR, and they will use the EIR in making decisions on this project.

This EIR is related to several other EIRs. As Russ noted, this project previously was evaluated in the supplemental water project EIR, which was certified in 1999 and decertified in 2002.

The 1999 EIR tiered from the Monterey Amendment Program EIR which also was decertified. Because the Monterey Amendment is once more undergoing environmental review, the present EIR considers impacts both with and without the Monterey Amendment in place.

The project also is evaluated programmatically in CLWA's capital program and water plan EIR.

The description of the environmental setting is usually based on conditions that are present at the time that the notice of preparation is issued. This project, however, was the subject of an earlier EIR and the transfer already has been implemented.

In order to capture any changes that could have resulted from the transfer, this EIR considers both the conditions that were present at the time that the original notice of preparation was issued, around 1998, as well as current conditions.

Information is provided for all three geographic areas evaluated in this EIR, including those associated with State Water Project facilities and the Wheeler Ridge and CLWA service areas.

No significant direct impacts were identified in the EIR. It was determined that the project would remove an obstacle to growth and that significant, indirect, growth-related impacts on all resources could occur in the CLWA service area.

Most of these impacts would be mitigable to less than significant, although impacts to aesthetics, air quality, biology, transportation, and solid waste disposal may be unavoidable.

This EIR looks at the cumulative impacts of this project when added to other closely related projects in all three geographic areas. No significant cumulative impacts were associated with the State Water Project or the Wheeler Ridge service area.

Cumulative impacts in the CLWA service area were the same as the growth-related impacts since they would result from the same types of land development.

This EIR considers a variety of alternatives to the project, including: No project, increasing groundwater extractions, exchanging desalinated water for State Water Project water, transferring a smaller Table A amount, and transferring a larger Table A amount.

With the exception of transferring a smaller Table A amount, all of the alternatives would have greater direct impact than the proposed project. Transferring a smaller Table A amount would lessen the project's growth-related impacts, but would not meet the project objective related to augmenting CLWA's water supply to meet existing demand and a portion of future demand.

Thus, the proposed project is identified as the environmentally superior alternative.

Several areas of controversy have been identified. As mentioned earlier, the Monterey Amendment EIR is being revised. Because of the uncertainty surrounding this action, the present EIR evaluates impacts both with and without the Monterey Amendment in place.

Additionally, the potential for growth inducement from increased water supply is an area of known controversy, as is the amount of groundwater available to the Santa Clarita Valley.

I'm going to turn to back to Marylou Cotton.

MS. COTTON: As Lorraine mentioned and Rob mentioned, this is a extremely complex EIR, and has a couple of special features that we don't commonly find in other EIRs.

There are two additional appendices in the EIR. Appendix C is a study that was done by Northwest Economic Associates on the agricultural resources in the Wheeler Ridge-Maricopa Water Storage District service area. It explains the economic rationale for why certain member units of the Kern County Water Agency wish to sell part of their SWP Table A amounts in the first place, the reasons they wanted to do that. It discusses how they came to that conclusion and any impacts that might be caused by that.

Appendix D is something I'll just say that we are rather proud up of. It's a technical data for hydrologic analysis appendix. It was done by a person named Nancy Clemm, who is a professional engineer. Very well known in the State Water Project family. It is a very complex analysis, as Lorraine mentioned, with and without the terms of the Monterey Amendment of the reliability of CLWAs (inaudible) supplies, the project in general and Wheeler Ridge's -- impacts of Wheeler Ridge's supplies. That appendix is something that is the underpain for some of the conclusions that are present in the EIR.

MR. BEHRENS: As you know, the public comment period ends August 16th. It opened on June 17th. We're going to be receiving these comments tonight. We have a court reporter here that's taking all these comments down that we receive. And the staff will then consider the responses to those comments and report to the board at a later time after the comment period ends, so we can collect not only the comments we received tonight, but those in writing that we receive prior to August 16th.

That report will then be put together, the comments analyzed, and responses to the comments formulated, a matrix prepared for you to review with the staff in a presentation at a future board meeting. We anticipate that the process will be completed, according to the staff's schedule anyway, in November and then for final consideration for certification in December.

That concludes our presentation, Mr. Chairman. And it would be appropriate at this time now to open up the public hearing.

MR. KAVOUNAS: Very well, Mr. Behrens. Thank you. And thank you to all the staff that worked to to prepare this presentation.

I now open the public hearing. I have cards from three speakers that wish to address the agency and the board. If anybody else would like to address the agency, please feel free to fill out a public comment card that is located on the table by the door.

I'd like to call a Ms. Lynne Plambeck.

MS. PLAMBECK: Hi. I'm here speaking as an individual citizen tonight. I'd just like to express my concern that this EIR is proceeding without completion of the Monterey Agreement. I 102

think the court was fairly concise about the need 102
for the programmatic EIR in both legal decisions,
and they were also very -- very concerned about the 103
lead agency, and Castaic Lake Water Agency is not 104
the right lead agency. It was my understanding prior to this that the two EIRs were moving forward in tandem and they would be completed simultaneously.

And I just think that -- that the folks up 105
north that challenged the EIR will probably continue to challenge the EIR and that they're going to be very concerned that this is proceeding in a manner that's not consistent with an appellate court decision that they won, and that means that even though you know that's there and you're going ahead and doing this anyway, and it sort of seems like a waste of taxpayer's money since there's already a published appellate court decision on it.

And so I would just ask you to keep that in mind and that it might be the better part of valor to move the two EIRs forward in tandem as I understood had been originally planned. Thank you.

MR. KAVOUNAS: Thank you, Ms. Flambeck.

Mr. Vince Bertoni for the City of Santa Clarita.

MR. BERTONI: Thank you. Vince Bertoni, interim director of planning and building services for the City of Santa Clarita here on behalf of the City of Santa Clarita.

First, I'd like to thank the board for providing us this opportunity to comment on the project, on the EIR. You have extended the public comment period beyond the normal 45 days to 60 days. You have also held the public hearing during your comment period, which is not required under CEQA, so you've gone above what's the minimum under CEQA and the City appreciates that and also appreciates being provided with all the documentation very quickly and promptly throughout the whole process. So first off, we'd like to thank you for that. 106

Second off, I noticed that by sharing on EIR for water transfer, it's not really the water transfer itself. In regards to the water transfer, I would just say that as we reviewed the EIR it appears that this EIR was prepared for water transfer that would allow to you a few things. One of them would be to provide more reliability in the existing water supply. The other would be to allow for growth that's already been anticipated under existing general plans for both of the City of Santa 107

Clarita and the County of Los Angeles. 107

So to that extent, the City is supportive of that. The City has always been supportive of additional water reliability and also to make sure that as we plan for our future growth, we will have water supplied for that.

This city has a couple very high-profile projects that it is very important to the City and the point being the City to have adequate water supply for that.

As you know, we're very -- a housing rich city. We are trying to balance that out to be as equally jobs rich and so things such as our employments such as the Center Point Business Park to the south of you or the Gate (inaudible) project in Newhall are very important for the City, very important for the City's goals.

So to the extent that this would provide water for that, that's an important City goal. Also, things such as the redevelopment of downtown Newhall and that revitalization would require some additional water. So the supply part of it, the City is supportive of that additional reliability of water supply.

We reviewed the EIR at the City and we 108 reviewed it under the -- to see if it adequately addressed the potential environmental impact to the City of Santa Clarita, and our review indicated that it has. So at this time we have no comment on the EIR and would happy to answer any questions. Thank you. 108

MR. KAVOUNAS: Thank you, Mr. Bertoni. Thank you for taking the time.

Dana Wisehart, United Water Conservation District.

MS. WISEHART: Good evening. And as you've mentioned, I am Dana Wisehart, the general manager of the United Water Conservation District. I provided written comments, but if you don't mind, I'd just like to read some excerpts of the comments into the record.

MR. KAVOUNAS: Please.

MS. WISEHART: The United Water Conservation District has reviewed the draft EIR for the purpose -- for the proposed transfer of 41,000 acre-feet of state project water that will come from the Kern County Water Agency's member unit Wheeler Ridge-Maricopa Water Storage District to the Castaic Lake Water Agency. This proposed transfer of State Water Project water is beneficial to the Santa Clara 109

River Watershed and is fully endorsed by United Water. 109

The permanent transfer of 41,000 acre-feet 110
of State Water Project water to the Castaic Lake Water Agency provides a valuable additional source of water for the Santa Clarita Valley. This additional water improves the potential for conjunctive use of water within the valley. This is especially important given the urbanization of this area. Increased surface water supplies should provide water managers throughout the basin more flexibility with respect to the magnitude of additional groundwater pumping needed to meet the escalating M&I demand for water within the basin.

As an ongoing general comment to all water purveyors within the Santa Clarita Valley, United Water has a very real interest in the continued health of the Santa Clarita groundwater basin and the flow of the Santa Clara River. United Water represents the collective interests of downstream residents that depend on the flow of the Santa Clara River for recharge to groundwater, surface water diversions, and environmental mandates.

United Water's goal is that the quantity 111
and quality of water associated with the flow of the

Santa Clara River into Ventura County not be diminished. The development and implementation of the inter-agency regional monitoring program of groundwater levels, groundwater quality, surface water flows, and surface water quality -- and you know I am talking about the MOU agreement that we all signed with your upstream purveyors -- should provide ongoing data with respect to the relative health of the Santa Clarita and downstream basins as well as surface water. 111

In the event that surface water flow into Ventura County is diminished in either quantity or quality and can be reasonably linked to overpumping of the aquifer systems and/or surface water discharges to the river within the Santa Clarita Valley, United Water would seek to remedy the problem.

We appreciate the efforts of the Castaic Lake Water Agency to appropriately plan and augment the water supplies of our watershed as represented by this water transfer project.

As I said, my comments do have additional focus on the availability of the -- of the water, but that is covered in your EIR, so I'm not going to read it tonight. Thank you. 112

MR. KAVOUNAS: Thank you.

MR. BEHRENS: May the record show that the letter dated the July 26th from United Water Conservation District signed by Dana Wisehart is made part of the record of the proceedings tonight.

MR. KAVOUNAS: Thank you, Mr. Behrens.

MR. BEHRENS: Thank you, Mr. Chairman.

MR. KAVOUNAS: Mr. Ed Dunn.

MR. DUNN: My name is Ed Dunn. For those that don't know me, I was former I was former director of the Newhall County Water District and former director of this agency, and I remember when I was on this agency there was urban water event or plan that was done, and since then there have been various EIRs and I listened to the lady speak on the EIR tonight and she made mention that these transfers would be transported to the Santa Clarita Valley by way of the state aqueduct.

When talking to DWR and asking how that happened, because this agency used to have originally a 23,000 acre-feet per year allocation from the state, that the state DWR would transfer and transport to Castaic Lake for Castaic Lake Water Agency, but DWR also had allocations from many farmers and other water users in the San Joaquin 113

Valley. DWR said that those allocations the CLWA had been subsequently purchasing were designed to take turn-outs in the San Joaquin Valley, and those acre-feet were to get off in the San Joaquin Valley. 113

In other words, they were telling me that the Tehachapi pumping station and the aqueduct, that is I guess mostly owned for use by the Metropolitan Water District, was not designed to transport those farmers' allocations here.

So I have asked when I was on the agency and I have asked as a public comment when I'm not on the agency what contracts do you have with Metropolitan Water District or DWR that says you can transport that water that you are purchasing, those additional purchases here? Doesn't matter if you've banked them up there. Some day you will want to transport them here, and I am told there are no such contracts.

We know now that since the Arizona and those people are cutting off MWD's allocations by way of Colorado River, MWD now has to rely more heavily on the DWR and their allocation in this aqueduct and the capacity in the aqueduct. Many unaware, even in our community, that Castaic Lake Water Agency only has 5,000 acre-foot of storage in the Castaic Lake. Many think we've got a real good reservoir here, and we'll really high and dry. 113

And so with the demand that MWD is going to have on the aqueduct now more so demand 'cause you can't get it from the Colorado River, and with the drought situations, and this agency has no contracts that they can transfer those additional allocations here, and I heard nothing in the words tonight just like it was going to be transferred. Nothing was in the Urban Water management plan. It kind of scares me that we're going to sit here in the drought situation and MWD is going to need their full capacity of Castaic Lake and their full capacity of the state aqueduct, and all this water you purchased you can't bring here.

I would like to see that addressed in the EIRs. I would like to see that addressed in the urban water management plans that you can bring this water here. Thank you.

MR. KAVOUNAS: Thank you, Mr. Dunn.

Next is Mr. Larry Manikin.

MR. MANIKIN: I have bolded my comment, and I still have to put my glasses on.

Thank you for the opportunity to make public comment on tonight's issue concerning the transfer and ultimate storage of potentially 41,000 acre-feet of State Water Project water.

First, I am Larry Manikin, and president of the Santa Clarita Valley Chamber of Commerce. Our organization is the largest business association in the region with, as of last week, nearly 1,700 business members. There is no issue more important 114
in the future of this community than the availability of water. Having available water impacts almost every segment of this community business and consumer marketplace. Having water, as all of you know, is about planning. It's about, again, as all of you know, it's about having local agency being aggressive in the way they find and bring new water into the valley, and most importantly, it's about the economic future of the Santa Clarita Valley.

My job as president of the Chamber achieved spokesman of the business community is twofold. First, I work with companies from outside of the this market and try to encourage them to locate their company or business here. I am heavily involved in business recruitment.

Second, and probably more importantly, I am actively involved with working with local companies

to assure that they have the right kind of 114
political, economic, and physical infrastructure in place to make it possible for them to grow their respective businesses.

Regional economic analysts have predicted -- and I heard this at a meeting this spring -- they predicted that we will generate some 4,700 new jobs here in the valley this year alone. I suspect we're ahead of that pace already.

In looking at specific projects, one project, Center Point Business Park which is now under construction will generate an estimate -- estimated 8,000 new jobs over the next few years.

Many other such project are either now on the books or have actually started development. There is no issue more important to many of these companies than knowing that one, two or ten years from now they can turn on a water facet and actually have water flow out of it.

The issue you are discussing this evening will provide these companies with some sense of security that water, in fact, can and will be available to them during times of drought.

I highly encourage you to continue to make the necessary decisions that can and will make these

new water resources available to both our existing 114
business community and to those businesses that will soon call us home in the future. Thank you.

MR. KAVOUNAS: Thank you, Mr. Manikin.

The last comment card I have is from Mr. Terra Donlon.

MS. DONLON: Good evening. My name is Terra Donlon. I'm the director of government affairs for the building industry association.

On behalf of approximately 400 companies and their representative employees who make up the Greater L.A./Ventura chapter the BIA, thank you for your opportunity to comment this evening.

BIA is pleased to see that CLWA has 115
produced a new EIR for the litigation pending on the transaction which can be resolved. The CLWA transfer of 41,000 acre-feet of water from Kern County in 1999 represented wise water planning at the time for the Santa Clarita Valley. Such planning and water management programs on the part of CLWA ensures that its current users as well as future users will be assured safe and reliable drinking water.

BIA would like to commend CLWA and its agency and staff for taking these preemptive actions and we urge you to support and certify this EIR. 116

MR. KAVOUNAS: Thank you very much, Ms. Donlon.

MR. BEHRENS: Mr. Chairman, we have a letter here dated July 28, 2004 to Mr. Dan Masnada from BIA signed by Terra Donlon and Ray Pearl. I'd like to make this part of the record.

MR. KAVOUNAS: Very good.

MR. BEHRENS: Thank you, Mr. Chairman.

MR. KAVOUNAS: I have no other requests from anyone to speak to the board to comment on this draft EIR. And I see no hands from the audience. At this time I will close the hearing. And I'd like to thank everybody for coming out and giving us their thoughts and opinions on the EIR.

(Hearing concluded at 7:44 p.m.)

Re: 41,000 AF Transfer of water from farmland to Santa Clarita (SCH#19908041127)

Dear Ms. Cotton:

Endangered Habitats League is concerned that your agency is the wrong lead agency for this project. Water transfers are a statewide issue that induce growth and reduce water for farming. They should be addressed by an agency that is qualified under state law to address statewide impacts and will notify all interested parties. In this case, this is the Department of Water Resources. **117**

The impacts of this transfer are considerable and affect a wide variety of interest, yet sufficient notification has not occurred, for example to our group. **118**

If such a major transfer is allowed to proceed under the lead agency status of a small regional water agency, it will set a precedent that will affect many major water decisions throughout the state of California. It is imperative that this major change in state policy receive full environmental review and comments from all affected parties. We therefore request that this project be re-noticed by the Dept. of Water Resources acting as lead agency as a project of statewide concern so that all impacts may be disclosed and properly addressed. **119**

Sincerely,

Dan Silver, MD

NOTICE OF COMPLETION FOR DRAFT ENVIRONMENTAL IMPACT REPORT CASTAIC LAKE WATER AGENCY SUPPLEMENTAL WATER PROJECT TRANSFER

Dear Ms Cotton:

This is in response to the Notice of Completion for the Draft Environmental Impact Report for the Castaic Lake Water Agency Supplemental Water Project Transfer. The County of Los Angeles Public Library has reviewed the document and determined that this project will not have an impact on library services. 120

If you have any questions, or need additional information, please feel free to call Malaisha Hughes at (562) 940-8455.

Sincerely,

RE: **Comments on the Draft Environmental Impact Report for the Castaic Lake Water Agency Supplemental Water Project Transfer – SCAG No. I 20040379**

Dear Ms. Cotton:

Thank you for submitting the **Draft Environmental Impact Report for the Castaic Lake Water Agency Supplemental Water Project Transfer** to SCAG for review and comment. As areawide clearinghouse for regionally significant projects, SCAG reviews the consistency of local plans, projects, and programs with regional plans. This activity is based on SCAG's responsibilities as a regional planning organization pursuant to state and federal laws and regulations. Guidance provided by these reviews is intended to assist local agencies and project sponsors to take actions that contribute to the attainment of regional goals and policies.

It is recognized that the proposed Project considers the transfer of 41,000 acre feet of State Water Project Table A amount from Kern County Water Agency, and its member district the Wheeler Ridge-Maricopa Water Storage District, to the Castaic Lake Water Agency.

SCAG staff has evaluated the **Draft Environmental Impact Report for the Castaic Lake Water Agency Supplemental Water Project Transfer** for consistency with the Regional Comprehensive Plan and Guide and Regional Transportation Plan. The Draft EIR includes a discussion on the proposed Projects' consistency with SCAG policies and applicable regional plans, which were outlined in our February 19, 2003 letter on the Notice of Preparation (NOP) for this Draft EIR.

The Draft EIR, in Section 5.0, Consistency with Adopted Plans and Policies, cited SCAG policies and addressed the manner in which the proposed Project is consistent with applicable core policies and supportive of applicable ancillary policies. This approach to discussing consistency or support of SCAG policies is commendable and we appreciate your efforts. **121**

Based on the information provided in the Draft EIR, we have no further comments. A description of the proposed Project was published in the June 16-30, 2004 Intergovernmental Review Clearinghouse Report for public review and comment.

If you have any questions, please contact me at (213) 236-1867. Thank you.

Sincerely,

Jeffrey M. Smith

Section 3 – Responses to Comments

3.0 RESPONSES TO COMMENTS

This section includes excerpted comments from the letters and public meeting transcript included in Section 2 and corresponding responses in tabular format. For ease of cross-referencing, the comments in the table have been numbered sequentially in the left-hand column. The acronyms used to define the commenters are as indicated in Section 2; comments provided during the public meeting on July 28, 2004 are indicated by "PM," and the name of the commenter is shown in parentheses. This section also includes a Master Response, which addresses similar issues raised by a number of commenters.

This page intentionally left blank.

Matrix of Comments on DEIR and Responses
CLWA - Supplemental SWP Table A Amount Transfer Project FEIR (41,000 AF)

No.	Commenter	Comment	Response
1	Caltrans	The Project would not involve construction or operational changes that could generate traffic or otherwise affect traffic conditions. Based on the information received, we have no comments at this time. Thank you for the opportunity to have reviewed this project. Any transportation of water which requires the use of oversize-transport vehicles on State highways will require a Caltrans transportation permit. We recommend that large size truck trips be limited to off-peak commute periods. Thank you for the opportunity to have reviewed this project.	This comment is noted; no text revisions are required. The Project does not involve the use of trucks to transport water.
2	DWR	The Department of Water Resources' (DWR) staff have reviewed the Draft Environmental Impact Report (DEIR) for the Castaic Lake Water Agency Supplemental Water Project Transfer of 41,000 Acre-Feet of Table A Amount (SCH No. 1998041127), and found that the document adequately and thoroughly discusses the proposed project and its impacts. The DEIR discusses the effects of the project on the environment and State Water Project (SWP) and uses baseline conditions consistent with those being considered for inclusion in the DEIR. DWR is currently preparing for the Monterey Amendment to the State Water Project Contracts (including Kern Water Bank Transfer and Other Contract Amendments and Associated Actions as Part of a Proposed Settlement Agreement in Planning and Conservation League v. Department of Water Resources (SCH No. 2003011118), referred to hereafter as "Monterey Plus."	This comment is noted; no text revisions are required. DWR, as a responsible agency for the DEIR and as lead agency for the new Monterey Amendment Program EIR, has reviewed the DEIR and has concluded that the DEIR adequately and thoroughly describes the Project and adequately analyzes all Project impacts on the environment and SWP system, using baseline conditions consistent with those DWR intends to use for its Monterey Amendment EIR. DWR's evidence refutes comments by members of the public which speculate that the DEIR will be inconsistent with the new Monterey Amendment Program EIR or that the DEIR fails to consider Project environmental effects which will be considered in the Monterey Amendment EIR.
3	DWR	The DEIR provides a good discussion of the relationship between the 41,000 acre-feet Table A transfer and the current Monterey Plus process. DWR will analyze the effects of all Table A transfers that were part of the Monterey Amendment to the SWP contracts in the Monterey Plus EIR. The proposed CLWA 41,000 acre-feet Table A transfer will be included in this analysis.	This comment is noted; no text revisions are required. DWR, as a responsible agency for the DEIR and as lead agency for the new Monterey Amendment Program EIR, has reviewed the DEIR and has concluded that the DEIR provides a good discussion of the relationship between the Project and the Monterey Amendment.

No.	Commenter	Comment	Response
4	DWR	One of the tools being used by DWR to assess potential impacts associated with these Table A transfers is the CALSIM II model. DWR acknowledges that CLWA used an earlier model, DWRSIM, to analyze the effect of the 41,000 acre-feet transfer; however, DWR will use the next generation model, CALSIM II, to assess potential impacts associated with all Table A transfers in its DEIR for Monterey Plus. The use of CALSIM II may cause slight changes in results, which may lead DWR to different conclusions than the conclusions made by Castaic Lake Water Agency in the current DEIR.	CLWA used DWRSIM model studies to assess potential future impacts of the Project because at the time the supply analyses were begun for the DEIR no CALSIM II studies were publicly available. At that time, the DWRSIM studies used in DEIR analyses were the most comprehensive studies that were publicly available. These studies were conducted by DWR for CALFED in 1998 and had received extensive public and technical review during the CALFED process. Additionally, these studies were consistent with the pre-Project baseline conditions in 1998 when CLWA approved the Project. (See DEIR Section 3.0 at p. 3.0-6, DEIR Section 3.15.2.2 at p. 3.15-31) CLWA's use of the DWRSIM model did not result in significantly different SWP delivery reliability results than would have been obtained using the CALSIM II model. Overall, the SWP delivery reliability results from DWRSIM studies prepared for CALFED were slightly higher than delivery reliability results from the CALSIM II studies that subsequently became available in the DWR SWP Delivery Reliability Report. Therefore, from an environmental impact assessment standpoint, the DEIR analyzed the worst-case scenario; i.e., the scenario that would result in greater direct and indirect impacts in both the CLWA and WRMWSD service areas. (See DEIR Appendix D, Section 2.2 and Figures 2-1 and 2-2 at pp. D-19 to D-21) A comparison of DWRSIM and CALSIM II results of total SWP deliveries shows a somewhat larger difference for the comparison at "existing" demand conditions than at 2020 demand conditions. (See DEIR Appendix D, Section 2.2 and Figures 2-1 and 2-2) The differences between the two model results at existing demand conditions are mainly attributable to the use of a different "existing" demand for each study. Both studies used DWR estimates of Contractor demands that were "existing" or current at the time the studies were conducted, i.e., 1998 for the DWRSIM study and 2001 for the CALSIM II study. The 2001 total SWP demand is higher than the 1998 total

No.	Commenter	Comment	Response
4 (cont)	DWR		SWP demand due to increased M&I Contractor demands. Because the models only make deliveries up to Contractor demands (as opposed to making deliveries up to the Contractors' maximum Table A Amounts), the deliveries shown in the wetter years, when adequate supply is usually available, are limited by demands. Therefore, for current conditions, the DWRSIM study shows lower deliveries than the CALSIM II study in the wetter years, not because supplies are not available, but because the lower Contractor demands used in the DWRSIM study limit deliveries. In addition, the lower demand can also result in more water being delivered in some dry years, if more water was left in storage at the end of the preceding year. The differences between the two model results at 2020 demand conditions are much smaller because both studies use the same demands. Differences in SWP deliveries between these two model studies result from other factors such as changes in assumptions for regulatory standards and operating criteria, and differences in certain algorithms used in the models. It should be noted that CLWA did use CALSIM II model results to estimate SWP water supplies for the current environmental setting. DWR's comment indicates that DWR will also use the CALSIM II model to assess potential impacts associated with Table A Amount transfers in its Monterey Amendment EIR. Thus, CLWA anticipates that the DEIR and the Monterey Amendment EIR will be consistent in their projections of impacts related to the Project. (See DEIR Section 3.15.2.2 at page 3.15-31 and DEIR Appendix D Section 6.1.2.2; See also DEIR Sections 6.3.1.5, 6.3.2.6 & 6.3.3.4)
5	DWR	As final comments, DWR notes that this DEIR adequately discusses the reliability of the SWP, pre- and post-Monterey Amendment conditions, future conditions, and SWP operations.	This comment is noted; no text revisions are required. DWR, as a responsible agency and as lead agency for the Monterey Amendments EIR, has reviewed the DEIR and has concluded that the DEIR adequately discusses SWP operations, SWP reliability, pre- and post-Monterey Amendment conditions, and future conditions as they relate to the Project. DWR's evidence refutes comments from other parties that speculate

No.	Commenter	Comment	Response
5 (cont)	DWR		that the DEIR fails to adequately discuss SWP operations, SWP reliability, pre- and post-Monterey Amendment conditions, and future conditions, and that speculate that such DEIR discussions are contrary to the discussions anticipated for the Monterey Amendment EIR.
6	DWR	Coordination between DWP and CLWA is essential to produce accurate environmental documentation that leads to informed decision-making and full public disclosure as the California Environmental Quality Act mandates. DWR appreciates inclusion and consultation in the early stages of preparation of this DEIR. Please ensure that DWR's Division of Environmental Services and SWP Analysis Office receive copies of the Final EIR.	DWR states that it was included and consulted in the early stages of preparation of the EIR in order to provide accurate environmental documentation leading to full public disclosure and informed decision-making. DWR's evidence refutes comments from other parties that speculate that, without DWR as the lead agency, the DEIR will not have the benefit of DWR statewide authority and expertise. As requested, CLWA will provide to DWR's Division of Environmental Services and to DWR's SWP Analysis Office copies of the FEIR for the Project.
7	CHP	In reviewing this project, our concern was what effect these projects will have on traffic. It is our opinion there should not have a significant impact.	This comment is noted and is consistent with the EIR analysis; no text revisions are required.
8	SWC	This letter provides comments on the Draft EIR entitled "Supplemental Water Project Transfer of 41,000 Acre-Feet of State Water Project Table A Amount," on behalf of the State Water Contractors ("SWC"). As you know, the SWC represents nearly all contractors that receive water from the State Water Project ("SWP"). Thus, the SWC is vitally interested in the proper application of CEQA to water transfers under Articles 41 and 53 of the SWP water service contracts and, in general, with respect to operations of the SWP. The SWC commends Castaic Lake Water Agency ("Castaic") for going far beyond what is required by CEQA and the appellate court decision that invalidated Castaic's earlier EIR for the 41,000 acre foot water transfer. Both the trial court and the appellate court found that all of the environmental analyses contained in that first EIR complied with CEQA, except for reliance (through "tiering") on the original Monterey Amendment EIR which had later been found inadequate by the Third District Court of Appeal. Nevertheless, Castaic has taken	This comment is noted; no text revisions are required.

No.	Commenter	Comment	Response
8 (cont)	SWC	a comprehensive, fresh look at the transfer's potential impacts in a single document, when arguably a short supplement eliminating the references to the Monterey Amendment would have sufficed. By so doing, you have provided decision makers with a complete picture of the transfer and its impacts so they can make new informed decisions related to the project.	
9	SWC	During scoping, several parties made suggestions that this Supplemental EIR should not move forward until the new EIR for the Monterey Amendment has been completed. The SWC suggests that Castaic should respond more directly to these contentions. Those contentions overlook or intentionally mischaracterize a central element of the Monterey EIR litigation Settlement Agreement. The Settlement Agreement explicitly states that the SWP will operate under the Monterey Amendment while the new EIR is prepared. This includes operation under Article 53, pursuant to which the Kern County Water Agency consented to up to 130,000 acre feet of agriculture to urban transfers. Suggestions that consideration of such transfers must await completion of the new Monterey Plus EIR would render this element of the Settlement Agreement a nullity, contrary to the clear understanding of the signatories to that document.	CLWA concurs with these comments. Please refer to the Master Response, particularly Section V thereof.
10	SWC	Further, nothing in the Settlement Agreement affects the rights of contractors and DWR to agree to and proceed with implementing long-term transfers of Table A Amounts. In this respect, the draft Supplemental EIR contains a confusing statement to the effect that certain terms in the Settlement Agreement constitute a "specific exclusion" of the 41,000 acre foot transfer from "any prohibitions against transfers of Table A amounts by the Settlement Agreement." The Settlement Agreement does not contain any such prohibitory language. Thus, specific exclusions are not necessary. The final Supplemental EIR for the 41,000 acre foot transfer should point out that several other Table A transfers have been consummated since the Settlement Agreement was executed and that the Settlement Agreement contains no language that	The comment correctly points out that the Monterey Amendment Settlement Agreement, approved by the Sacramento County Superior Court, allows the Monterey Amendment to remain in effect until certification of a new Monterey Amendment Program EIR. Monterey Amendment provisions allowing long-term transfers of Table A Amounts remain valid. (See DEIR 1.2.2 and 1.4.2) Thus, the language contained at DEIR Page ES-4, lines 20-31, and at DEIR Page 1-4, lines 13-23, should be deleted and replaced with the following: "The Monterey Amendment Settlement Agreement does not require that the new Monterey Amendment Program EIR be certified before an EIR for this Project can be certified, nor does

No.	Commenter	Comment	Response
10 (cont)	SWC	could be interpreted as prohibiting such transactions or the 41,000 acre foot transfer.	it require that the EIR for this Project tier off the new Monterey Amendment Program EIR. Also, the Monterey Amendment Settlement Agreement does not require that the new Monterey Amendment Program EIR serve as the EIR for this Project. Section III(C)(4) of the Monterey Amendment Settlement Agreement only requires DWR to analyze the potential impacts resulting from this Project and other transfers as they relate to the potential environmental impacts of approving the Monterey Amendment. Section III(E) of the Monterey Amendment Settlement Agreement clarifies that the Section III(C)(4) analysis is limited by remedies or other actions of the Los Angeles County Superior Court in *Friends I*, stating: With respect to Section III(C)(4)(b) regarding the Kern-Castaic Transfer, the Parties recognize that such water transfer is subject to pending litigation in the Los Angeles County Superior Court following remand from the second District Court of Appeal (*See Friends of the Santa Clara River v. Castaic Lake Water Agency 95 Cal.App.4th 1373, 116 Cal.Rptr.2d 54 (2002); review denied, April 17, 2002*). The Parties agree that jurisdiction with respect to that litigation should remain in that court and that nothing in this Settlement Agreement is intended to predispose the remedies or other actions that may occur in that pending litigation." Several transfers have taken place since the Monterey Amendment Settlement Agreement. All of those transfers have been approved pursuant to Article 41 of the State Water Project Contract. Those transfers evidence that it was not the intent of the parties to the Monterey Amendment Settlement Agreement to require certification of the Monterey Amendment EIR before transfers not listed as final in Attachment E to the Settlement Agreement could take place. Among non- Attachment E transfers that have taken place

No.	Commenter	Comment	Response
10 (cont)	SWC		since the Monterey Amendment Settlement Agreement are the following: • June 2, 2003: Tulare Lake Basin Water Storage District to Alameda County Flood Control and Water Conservation District, Zone 7, 400 acre-feet, effective 2003 • October 24, 2003: Metropolitan Water District of Southern California to Coachella Valley Water District, 88,100 acre-feet, effective 2005 • October 24, 2003: Metropolitan Water District of Southern California to Desert Water Agency, 11,900 acre-feet, effective 2005 • October 31, 2003: Belridge Water Storage District (KCWA) to Alameda County Flood Control and Water Conservation District, Zone 7, 2,219 acre-feet, effective 2004 • December 5, 2003: Tulare Lake Basin Water Storage District to County of Kings, 5,000 acre-feet, effective 2004 • February 23, 2004: Tulare Lake Basin Water Storage District to Coachella Valley Water District, 9,900 acre-feet, effective 2004
11	SWC	The SWC suggests that the final Supplemental EIR reference the July 14, 2004 trial court opinion in *California Water Network v. Castaic Lake Water Agency*, which discusses the proper lead agency for projects similar to the 41,000 acre foot transfer. In that case, the Court held that Castaic was the proper lead agency for a water banking project, stating "Castaic is the agency most deeply involved in the planning, and execution of this project." The trial court rejected the argument that DWR was the only proper lead agency when actions concerning the	This information is included in the Master Response. The comment regarding the knowledge and role of local agencies regarding local land use planning and local water supply issues is noted; local land use plans and their relationship to the Project and local water supply are discussed in the DEIR in sections 4.1 and 4.2.

No.	Commenter	Comment	Response
11 (cont)	SWC	SWP are involved. As in the *California Network Case*, Castaic is the agency promoting, planning, and primarily carrying out the 41,000 acre foot transfer. It is also the agency with the greatest knowledge about growth inducement and similar local issues. State government, including DWR, has no role in local land use planning and the local water supply issues that arise from planning decisions. The plenary role of local agencies in the land use arena should be pointed out in the final Supplemental EIR.	
12	SWC	The SWC has reviewed the water supply analysis set forth in the draft Supplemental EIR and believes it will provide valuable information for decision makers in determining how the 41,000 acre foot transfer will affect Castaic's ability to meet the future water needs engendered by Los Angeles County's and local cities' land use decisions. The SWC suggests that the final Supplemental EIR re-emphasize that urban water suppliers do not make the land use and growth decisions but instead, try to provide needed water supplies in the most economical and environmentally sound manner. From this standpoint, the draft Supplemental EIR provides the best information reasonably available from recognized scientific sources. More than that can not be asked of lead agencies dealing with highly complex natural and man made water systems.	CLWA concurs with these comments. The DEIR (sections 1.1 and 4.2) notes that CLWA is not a land use agency and does not control where and when growth will occur in its service area.
13	City SC	Thank you for allowing the City of Santa Clarita to comment on the Draft Environmental Impact Report for the Supplemental Water Project Transfer. At this time, the City of Santa Clarita has no comments on the draft document regarding the project.	This comment is noted; no text revisions are required.
14	LA DPR	Page 3.0-10 of the Draft EIR states that the "DWR's operation of these lakes (Quail, Pyramid, and Castaic) generally would not change with the Project, although the project would result in additional water transported through these lakes in about the same months the water is delivered to CLWA." Page 3.15-41 also confirms that "the amount of water stored at Castaic Lake would not be expected to change as a result of the Project." The	This comment is noted; no text revisions are required. As indicated, the Project would not change the operation of Castaic Lake.

No.	Commenter	Comment	Response
14 (cont)	LA DPR	optimum operating level of Castaic Lake is 1515 above sea level. Scheduling of the release of the SWP water should be done so to maintain this level. Assuming that this operating criterion and the physical conditions of the lake do not change as a result of the project, adverse impacts to Department facilities are not anticipated. The Department requests that any future changes in the operating criteria of the lake be coordinated directly with Mr. Dana Robertson, Parks Superintendent. Contact information is provided below: Mr. Dana Robertson, Parks Superintendent Castaic Lake Recreation Area 32132 Castaic Lake Drive Castaic, CA 91384 Phone (661) 257-4050/Fax (661) 257-3759	
15	LA DPR	Section 3.12.3 of the Draft EIR states that the implementation of the project will have no direct or indirect impacts to recreation within the CLWA. However, the potential development (Page 4-2) for 106, 700 new residents and 35,600 new units to house them may impact future recreation opportunities for those within the CLWA, and in turn, to future Castaic Lake operations.	With respect to impacts to recreation within CLWA, Section 3.12.3.3 of the DEIR states: "No direct significant impacts to recreational resources would occur; therefore no mitigation measures are required. Mitigation measures for indirect impacts are addressed in Chapter 4, Growth-Inducing Effects and Growth-Related Impacts." (A direct impact is a direct physical change in the environment resulting from the Project; an indirect impact is a reasonably foreseeable physical change in the environment resulting from the Project. [See *Friends of the Eel River v. Sonoma County Water Agency* (2003) 108 Cal.App.4th 859, 876-877.]) Those mitigation measures are referenced in DEIR Section 4.2.12. DEIR Section 4.2.12 concludes that indirect significant impacts are avoidable with those mitigation measures. Sections 3.12.3.1 and 3.12.3.2 state that no direct or indirect impacts to recreational resources of the SWP or WRMWSD would occur as a result of the Project. Thus, DEIR Section 3.12.4 concludes that there are no unavoidable direct or indirect significant impacts to recreational resources resulting from the Project.

16	LAFD	LAND DEVELOPMENT UNIT: The County of Los Angeles Fire Department, Land Development Unit appreciates the opportunity to comment on this project. However, this project does not propose structures or any other improvements that appear to have a significant impact that requires a comment from the Land Development Unit. Specific fire and life safety requirements for the construction phase will be addressed at the Building and Fire Safety plan check. There may be additional fire and life safety requirements during this time. Should any questions arise regarding subdivision, water systems or access, please contact Inspector Marvin Dorsey at (323) 890-4243.	This comment is noted; no text revisions are required.
17	LAFD	FORESTRY DIVISION: The statutory responsibilities of the County of .Los Angeles Fire Department, Forestry Division include erosion control, watershed management, rare and endangered species, vegetation, fuel modification for Very High Fire Hazard Severity Zones or Fire Zone 4, archeological and cultural resources, and the County Oak Tree Ordinance. The areas germane to the statutory responsibilities of the Los Angeles County Fire Department, Forestry Division have been addressed.	This comment is noted; no text revisions are required.
18a	VRMA	None	No comments were submitted.
18b	VPWA	None.	No comments were submitted.
19	SCERC	The Stanislaus County Environmental Review Committee (ERC) has reviewed the subject project and has no comments at this time.	No comments were submitted.
20	BIA	CLWA's transfer of 41,000 acre-feet of water from Kern County in 1999 represented wise water planning for the Santa Clarita Valley. The BIA is pleased to see that the CLWA has produced this new EIR so that the litigation pending on the 1999 transaction can finally be resolved.	This comment is noted; no text revisions are required. Indeed, by augmenting CLWA's supplies, the Project serves to mitigate anticipated water resource shortages for existing land uses and for land uses projected by local general and specific plans.

No.	Commenter	Comment	Response
20 (cont)	BIA	We are in the midst of a housing shortage in our State, especially in the Los Angeles and Ventura County regions. With housing supply in high demand it is critical for agencies such as CLWA to plan for future infrastructure needs. The continuance of such planning and water management programs is designed to enable the agency to meet its mission of providing water for anticipated growth in the Santa Clarita Valley. We support the Agency board and staffing in continuing that mission. CLWA has taken the proper steps to insure that its current users as well as future users will be assured safe and reliable water. The Building Industry Association would like to commend the CLWA for taking these preemptive actions.	
21	C-WIN	**CLWA is the Wrong Lead Agency and Must Wait for DWR to Complete the new Monterey Plus EIR.** Under the principles articulated by the 3rd District Court of Appeal in the PCLvDWR case (#CO24576), CLWA is not the proper lead agency in this transaction which has tremendous statewide significance as it necessarily must address the Monterey Amendments. DWR is the only proper lead agency.	Please refer to the Master Response.
22	C-WIN	This transfer is not consistent with the PCLvDWR settlement, reached in May of 2003, under which DWR has already commenced its own statewide review of the Monterey Amendments. Until the new EIR, known as "Monterey Plus" is finalized and the project is approved, the only transfers recognized as final are those listed in attachment E of the settlement. This is not one of those transfers and therefore would be illegal until completion and certification of the new "Monterey Plus" EIR. The CLWA proposed EIR is potentially on a collision course with DWR's "Monterey Plus" EIR and could produce a result that is at odds with the court mandated EIR on the Monterey Amendments currently being produced by DWR. C-WIN incorporates the January 10, 2002 letter from attorney Robert H. Clark to then General Manager of CLWA Robert C.	Please refer to the Master Response and to Comments 2, 3, 5, 6, 8, 9 and 10 and the Responses thereto. This Project is consistent with the Monterey Amendment Settlement Agreement. Section II of the Monterey Amendment Settlement Agreement provides that the Monterey Amendment will remain in place during preparation of the new EIR for the Monterey Amendment. Nothing in the Monterey Amendment Settlement Agreement prevents transfers from continuing to occur under the Monterey Amendment while the new Monterey Amendment Program EIR is being prepared. Section III(C)(4) of the Monterey Amendment Settlement Agreement only requires the Monterey Amendment EIR to analyze past, present and future transfers as they relate to the potential environmental effects of the Monterey Amendment. The Monterey Amendment Settlement Agreement's recognition of certain transfers as final and immune from challenge did not state nor imply that other

No.	Commenter	Comment	Response
22 (cont)	C-WIN	Sagehorn where he points out this problem and warns, "Alternatively, CLWA may choose to create an EIR that does not rely in any way on Monterey Amendment provisions, and then complete the 41,000 AF water entitlement transfer outside of Monterey. There are adverse financial implementations to this course of action, and any water transfer outside of Monterey—assuming it might be acceptable to Kern County Water Agency and Wheeler Ridge—*could be made subject to agricultural water deficiency provisions in the same manner that the Devil's Den water entitlement transfer was originally made subject to those agricultural water deficiency provisions" (emphasis added*) (See Attachment A). C-WIN also incorporates a letter from attorney Alyse M. Lazar to DWR Director Lester Snow dated May 18, 2004 and the response from Mr. Snow's office dated June 17, 2004. In the response letter, Mr. Snow says, "DWR's treatment of the transfer of Table A amounts from Kern County Water Agency to Castaic Lake Water Agency will be governed by the Settlement Agreement. As provided in Paragraph III.C.4 of the Settlement Agreement, the EIR will include an "analysis of the potential environmental impacts relating to (a) the Attachment E transfers, and (b) the Kern-Castaic Transfer, in each case as actions that relate to the potential environmental impacts approving the Monterey Amendments." Section 1(0) of the Settlement Agreement defines the "Kern-Castaic Transfer" as "the transfer of 41,000 AF of water from Kern County Water Agency to the Castaic Lake Water Agency, approved by DWR on march 31, 1999." DWR has not completed any draft or final analysis regarding these transfers." (See Attachment B).	transfers are prevented from becoming final. In fact, Section II(E) of the Monterey Amendment Settlement Agreement recognized that this Project is not subject to the jurisdiction of the Sacramento Superior Court in the *PCL* case. Instead, the Monterey Amendment Settlement Agreement acknowledged that environmental review for this Project is subject to the jurisdiction of the Los Angeles Superior Court. Because the May 5, 2003 Monterey Amendment Settlement Agreement provides for the Monterey Amendment to remain in effect, the issue addressed in the prior January 10, 2002 letter of Robert Clark referenced in this comment about the transfer being subject to pre-Monterey Amendment agricultural deficiency provisions is moot. Please also refer to Comment 45 and to the Response thereto. As noted in the Response to Comment 45, CLWA would benefit from the Project under pre-Monterey Amendment agricultural water deficiency provisions. Regarding the letter from Alyse M. Lazar, the fact that the new Monterey Amendment Program EIR will analyze the Project and other past, present and future transfers as they relate to the potential environmental effects of the Monterey Amendment does not necessitate that CLWA await the Monterey Amendment EIR before it can approve the Project. Indeed, the new Monterey Amendment Program EIR could take months to complete, and CLWA is under mandate of the Los Angeles County Superior Court in *Friends of the Santa Clara River v. Castaic Lake Water Agency* ["*Friends I*"], Los Angeles Superior Court Case No. BS 056954, to certify an EIR that complies with CEQA and is consistent with the views expressed in the Court of Appeal opinion in *Friends I* contained at 95 Cal.App.4th 1373.

No.	Commenter	Comment	Response
23	C-WIN	**The Proposed Transfer is Currently the Subject of Litigation.** The CLWA EIR states that CLWA has 95,200 AF of Table A SWP water. This is not accurate as the 41,000 AF from the sale by KCWA to CLWA under the old Monterey Amendments is the subject of ongoing litigation. Allowing development of new homes based on this challenged and uncertain source of water is not prudent or reasonable. C-WIN is currently a plaintiff in several cases against CLWA opposing proposed transfers that depend on the 41,000 AF transfer mentioned above. Any transfer that is dependent on a water source that is not free and clear is not reliable. C-WIN hereby incorporates our ongoing case against CLWA, the Department of Water Resources (DWR) and Semitropic Water Storage District , Civ No. 215327. Castaic is proposing to transfer 24,000 AF of its 2002 allocation of it's State Water Project (SWP) water, heavily relying on and siting the 41,000 AF transfer as complete to help justify the 24,000 AF transfer, and store it in the Semitropic Water Bank. This case is currently going to appeal.	The DEIR correctly states that the current CLWA Table A Amount is 95,200 AF. The judgment of the trial court on remand from the Court of Appeal in *Friends I* did not invalidate the 41,000 AF Project that is the subject of this DEIR. The trial court in that case did not enjoin any part of this Project. According to the trial court, "Respondent will not be prohibited from using the water to which it is entitled, but petitioner may renew its application for such prohibition based upon evidence of the actual use of such additional water for purposes it considers improper." In a subsequent appeal of the trial court's judgment on remand, in an unpublished opinion, the Court of Appeal affirmed that judgment. The comment states that the Project allows for the development of new homes. However, the Project does not constitute an approval for the development of new homes. As noted in DEIR Section 1.1, CLWA is not a land use agency that can approve new homes or other new development. That section appropriately cautions any land use agencies intending to rely on the Project for a water supply for development projects that "past water deliveries are not a guarantee of future water delivery rates." The delivery projections and reliability models mentioned in the DEIR are used to identify environmental impacts of this Project, not as environmental review for new development. The DEIR analyzes the indirect environmental effects of the Project—those impacts that could arise from future development using the water provided by the Project. The comment mentions the case of *California Water Network and Friends of the Santa Clara River v. Castaic Lake Water Agency* [*"Network"*], Ventura Superior Court No. 215327, wherein the Court refused to invalidate a water storage project. That 24,000 acre-foot storage project was a 10-year banking of water to firm up CLWA's water supply for existing uses, and was defined as not providing water to accommodate new development. (See DEIR Section 6.3.3.1) The trial court in *Network* upheld

No.	Commenter	Comment	Response
23 (cont)	C-WIN		CLWA's environmental review for the water banking project, and, as the comment indicates, the case is now on appeal. Nothing in the *Friends I* trial court judgment on remand or *Friends I* Court of Appeal opinion prevented the storage project addressed in *Network* from using a portion of the 41,000 acre-feet available in Year 2002.
24	C-WIN	As the EIR states, under current law, urban water suppliers must maintain updated water management plans (Urban Water Management Plans). CLWA's UWMP is currently being challenged in court for claiming to have more water than is actually available.	The Court of Appeal in *Friends of the Santa Clara River v. Castaic Lake Water Agency* (2004), 123 Cal.App.4th 1, ["*Friends II*"] ordered the trial court to vacate CLWA's approval of its UWMP based upon the Court's determination that the UWMP must address the timing for remediation of perchlorate contamination found in a limited portion of the groundwater basin. CLWA intends to adopt an amended or updated UWMP that fully discusses issues raised by the Court of Appeal. The invalidation of the UWMP does not constitute a new substantial environmental impact or an increase in the severity of an environmental impact for the Project. The DEIR does not tier off or rely on the UWMP for any information, including information regarding estimates of water supply, water use, water demand, or water supply reliability. As stated in DEIR Section 5.6, "Although information in the UWMP was considered in the analysis for the Project, an independent analysis and determination of environmental impacts was carried out for the Project." This Project is not a development project that would rely on the UWMP in the CEQA process. The "paper water" issue in *PCL* referred to misleading local land use planners as to how much water can be relied upon to serve the long-term needs of a development project. This DEIR does not use UWMP projections to determine the amount and reliability of this Project. DEIR Section 1.1 cautions any land use agencies intending to rely on the Project for a water supply for development projects that "past water deliveries are not a guarantee of future water delivery rates." The delivery

No.	Commenter	Comment	Response
24 (cont)	C-WIN		projections and reliability models mentioned in the DEIR are used to identify environmental impacts of this Project, not as environmental review for new development.
25	C-WIN	Public comments submitted on the recently finalized DWR "SWP Delivery Reliability Report" underscore the continuing problem that contractor estimates of reliability have frequently promised more water than is actually obtainable for building purposes. This EIR is representative of the "paper water" critically described in the 3rd District Appeal Court decision mentioned above. **Water Reliability as Stated in the Proposed EIR is Not Accurate**. This EIR, along with many other proposed developments in California, is dependent on the analysis by DWR and it's State Water Project Delivery Reliability Report, Final 2002, to give planners and the public accurate information on SWP water reliability. These numbers are critical because planners and the public count on them when considering water availability to meet future demand. This Reliability Report has been seriously criticized for overstating actual available supply, questionable modeling and simulations, and lack of proper peer review. C-WIN hereby incorporated this Final Report, including all of the published comment letters in Appendix B. Please make a special note of those letters submitted by Senator Michael Machado, Robert Wilkinson, Arve Sjovold, Joan Wells, Dr. Peter Gleick and myself. C-WIN also incorporates "A Strategic Review of CALSIM II and its Use for Water Planning, Management, and Operations in Central California" submitted by the California Bay Delta Authority Science Program Association of Bay Governments, December 4, 2003. This document raises significant questions about the accuracy of DWR's Delivery Reliability Report. In addition, C-WIN incorporates two letters, the first from Systems Analyst Arve R. Sjovold dated November 11, 2003, title, "Analysis of SWP Reliability of Delivery". (See	Please refer to Comments 4 and 5 and the Responses thereto. The "paper water" issue in *PCL* referred to misleading local land use planners as to how much water can be relied upon to serve the long-term needs of a development project. That issue might come up with reference to an EIR for a new development project or with reference to an urban water management plan upon which new development might rely. But it does not pertain to this DEIR that analyzes the environmental impacts of augmenting CLWA's existing water supply. Therefore, the reliability analysis for the DEIR helps determine the extent of environmental impacts (including indirect growth inducing impacts) to be analyzed, and nothing more. The delivery projections and reliability models mentioned in the DEIR are not used as environmental review for new development. DEIR Section 1.1 appropriately cautions any land use agencies intending to rely on the Project for a water supply for development projects that "past water deliveries are not a guarantee of future water delivery rates." The comment incorrectly states that the DEIR depends on DWR analysis from the 2002 Final State Water Project Delivery Reliability Report to give planners and the public accurate information on SWP water supply reliability. As set forth in DEIR Section 3.15.2.2 at pages 3.15-30 and 3.15-31, the DEIR assessed water supply reliability for this Project based instead on two independent model studies using the DWRSIM model conducted by DWR in 1998 for the 2000 CALFED Bay-Delta Program EIR. As set forth in the Response to Comment 4, the DWRSIM model studies provided the best estimates of SWP supply reliability that were available when DEIR supply analyses were conducted, and are consistent with the 1998 environmental setting used in this EIR.

No.	Commenter	Comment	Response
25 (cont)	C-WIN	Attachment C). The second is from PCL President Sage Sweetwood dated February 2, 2004 to Delores Brown of DWR raising grave concerns about the validity of the DWR model known as CALSIM II. (See Attachment D). C-WIN incorporates a table prepared by DWR dated 9/16/02 titled "Historical versus Modeled Table A Deliveries and Demands." This is a draft document released by DWR. The modeled deliveries are significantly above the actual historical deliveries…graphically showing what the Third District Court of Appeal was referred to when they sited the "paper water" in the system. (See Attachment E).	Since the DWRSIM studies were conducted, the modeling tool DWR uses to simulate operations has evolved (first to CALSIM I, and more recently to CALSIM II). However, while the modeling tool itself has changed, the criteria used in the models to simulate SWP operations have not significantly changed. While DWR has completed a more recent assessment of SWP reliability in its SWP Delivery Reliability Report using CALSIM II, the results of these new studies are comparable to the results of the DWRSIM studies (see DEIR Appendix D, Section 2.2 and Figures 2.1 and 2.2 for a comparison of these model study results). As set forth in the Response to Comment 4, the DWRSIM model SWP delivery reliability results were slightly higher than delivery reliability results from these CALSIM II studies. Therefore, from an environmental impact assessment standpoint, the DEIR analyzed the worst-case scenario, i.e., the scenario that would result in greater direct and indirect impacts in both the CLWA and WRMWSD service areas. DWRSIM, like CALSIM II, estimates the amount of water the SWP could deliver to Contractors in each month over the 73 years of operation, for a given set of facilities and operating constraints and for a given level of Contractor demand. The results are interpreted as the capability of the SWP to meet the assumed SWP demand, over a range of hydrologic conditions, for that assumed set of physical facilities and operating constraints. The DEIR uses results from the two DWRSIM studies to determine SWP water supplies for both the pre-Project environmental baseline and the Project environmental impact analysis. Results from the DWR SWP Delivery Reliability Report are only used in the DEIR to determine estimates of SWP water supplies for the current environmental setting. Because the DEIR only depends on the DWR SWP Delivery Reliability Report results to determine the current

No.	Commenter	Comment	Response
25 (cont)	C-WIN		environmental setting, criticisms of that Report referenced in the comment that are directed at assumed use of that Report and at use of the CALSIM II model for assessing water supply reliability are not valid. Nevertheless, CLWA has considered the letters referenced in the comment that refer to the DWR SWP Delivery Reliability Report, and the DWR responses thereto, and provides the following summary analysis of those comments. The DWR responses can be found at the same web site where the letters are located, www.swpdelivery.water.ca.gov. <u>10/21/02 Letter by Arve Sjovold of Citizens Planning Association and 3/24/03 DWR Response</u>: The primary criticism of the 2003 DWR Report was that it did not calibrate results to historical delivery records. The DWR response provided information regarding why past deliveries cannot accurately be used to predict future deliveries and therefore, why calibrating CALSIM II to historical deliveries is not appropriate. <u>10/31/02 Letter by Robert Wilkinson and 4/2/03 DWR Response</u>: The primary criticism of the 2003 DWR Report and CALSIM II model were that the model projects nearly a million acre-feet more than extracted from the Delta during the 1980s and 1990s. The Wilkinson letter asserts that the Report and model fail to take into account environmental and legal constraints. The DWR response refutes those contentions, explaining that current environmental regulations and Delta protection standards allow for more operational certainty of the SWP, giving an example of how CALSIM II accurately predicted the lower deliveries in the prior decades given prior legal and operational constraints. <u>08/29/02 Letter by Peter Gleick of Pacific Institute and 08/29/02 DWR Response</u>: The Gleick letter raises concerns very similar to those raised by the Wilkinson letter.

No.	Commenter	Comment	Response
25 (cont)	C-WIN		10/30/02 Letter by Michael Machado of California State Senate and 3/11/03 DWR Response: The Machado letter attaches Nov. 1, 2002 comments by Dennis O'Connor of the California Research Bureau on the Report. The O'Connor comments describe five major concerns with the Report: 1) recent deliveries lower than the modeled 2001 conditions; (2) year 2021 studies do not seem to reflect growth in upstream use; (3) CALSIM II has not been calibrated or verified; (4) the results appear inconsistent with previous estimates and models; (5) CALSIM II is not being used as designed. In response, DWR explained the following: (1) the report used 2001 demand conditions that are higher than historical demand. Therefore, during wetter years when deliveries are limited by demand and not supply, the model will show higher deliveries than historically to meet that higher current demand. During dry periods when supplies are limited, the model's delivery results, when adjusted to reflect historic conditions, are quite comparable to historic deliveries; (2) the model does account for growth in upstream consumptive use; (3) DWR continually checks CALSIM II to determine if it reasonably simulates water operations in the system; (4) of two model examples cited, the first model used a daily and not a monthly time-step as used in CALSIM II. Regarding the second example, DWRSIM results in CLWA's UWMP, DWR stated: "DWR understands that the [UWMP] incorporates a more conservative interpretation of the results of the referenced DWRSIM study. DWR supports and encourages local water agencies to apply the level of SWP reliability they determine is appropriate for their areas, taking into account local supplies, other imported supplies, demand-management programs and

No.	Commenter	Comment	Response
25 (cont)	C-WIN		local planning criteria. The DWP Delivery Reliability report should serve as a reference document to help clarify decisions that are made at the local level"; (5) CALSIM studies are best used as comparative studies. 10/19/02 Letter by Carolee Krieger of Citizens Planning Association and DWR 3/24/03 Response: This letter raises issues similar to those in the Sjovold, Gleick and Wilkinson letters. In addition to the comment letters to the DWR SWP Delivery Reliability Report, CLWA has considered the information regarding the CALSIM II model referenced in this comment and has determined that CLWA's use of the CALSIM II model for the limited purpose set forth in the DEIR is appropriate. CLWA makes note of the following with regard to the documents referenced in the comment: December 4, 2003 "A Strategic Review of CALSIM II and its Use for Water Planning, Management and Operations in Central California." While the peer review panel did identify a number of areas for model improvement in this document, that was a primary purpose for commissioning their review. However, they did not characterize any of these areas as so flawed that the model's results could not be relied on. In fact, the peer review panel's conclusions regarding the CALSIM II model on page 2 of this document states: "We believe the use of an optimization engine for simulating the hydrology and for making allocation decisions is an appropriate approach and is in fact the approach many serious efforts of this kind are using. It is a substantial improvement of the previous modeling approaches and provides a basis for consensus among federal and state interests. The modeling approach addresses many of the complexities of the CVP-SWP system and its water management decisions." And on page 20, they go on to state: "Few, if any, modeling organizations in the country have consistently done as good a job on model development and

No.	Commenter	Comment	Response
25 (cont)	C-WIN		application for such a large, complex, and controversial system as the modeling group which developed CALSIM II." The August 2004 joint response of DWR and the Bureau of Reclamation to this document can be found at baydeltaoffice.water.ca.gov/modeling/index..cfm under "Peer Review Response." February 2, 2004 Sage Sweetwood Letter. This letter does not contain any independent evidence regarding CALSIM II. The letter merely restates the December 4, 2003 Report's suggestions for improvements to the model. The letter also acknowledges the 2003 Reports conclusions about the usefulness of the model. November 11, 2003 Analysis of SWP Reliability of Delivery. The Analysis reviews the DWR 2003 State Water Project Delivery Reliability Report. The Analysis is based on calculations using CALSIM II, and does not contain an independent analysis of the CALSIM II model. The Analysis uses CALSIM II model published results to question the reliability estimates for the SWP contained in the DWR 2002 Report. According to the Analysis, the 2002 Report 76% level of reliability for average years must take into account actual contractor practices and contractor specific situations. Thus, the Analysis contains information that is not germane to whether CALSIM II is an appropriate model. Draft September 16, 2002 Chart of Historical vs. Modeled Table A Deliveries. The Chart does not contain sufficient information about what model is used or what data set is used, or who prepared the chart. The Chart also indicates it is in draft, and not final form. Assuming the chart is prepared by DWR and refers to the DWR SWP Delivery Reliability Report, the chart shows that historic deliveries have been limited by historic contractor demand in most years, and that in many of those years there was adequate water available to meet the higher demand used in the model study.

No.	Commenter	Comment	Response
26	C-WIN	Significant Cumulative Impacts Not Recognized. CLWA is continuing to speculatively and irresponsibly approve proposed developments incrementally based on the hope that they will successfully acquire this 41,000 AF of SWP Table A allocation from the Kern County Water Agency. C-WIN hereby incorporates the following comment letters to show just how much is being proposed incrementally using this contended source as final. The cumulative impacts are not being considered. This is very significant when the true reliability numbers for the actual water supply are factored in as well. ▪ The C-WIN January 1, 2004 objection letter to the CLWA on the Negative Declaration for a proposed 35,000 AF transfer for a Groundwater Banking Project that depends on this same 41,000 AF transfer. ▪ The C-WIN February 3, 2004 objection letter to the LA County Regional Planning Department on the proposed West Creek Project #98-008 to build 2,545 residential units that depend on this same 41,000 AF transfer. ▪ The C-WIN February 26, 2004 objection letter to the County of Los Angeles Regional Planning Department regarding the proposed River Valley Project No. 00-196 to build 1,444 residential units, 1.5 million square feet of non-residential mixed-use space, along with a 7 acre elementary school and public recreational facilities; this project also relies on this 41,000 acre foot transfer. ▪ The C-WIN May 4, 2004 letter to the Planning and building Services Department of the City of Santa Clarita regarding the proposed River Park Project No. 02-175 to build 1,183 residential units, heavily relying on this same 41,000 AF transfer.	The cumulative impacts of the projects referenced in the comment are considered at Sections 6.3.3.1 (CLWA projects) and 6.3.3.2 (DMS projects) of the DEIR. CLWA does not approve new development, and the Project includes no approval of new development. As noted in DEIR Section 1.1, CLWA is not a land use agency that can approve new development. That section appropriately cautions any land use agencies intending to rely on the Project for a water supply for development projects that "past water deliveries are not a guarantee of future water delivery rates." The delivery projections and reliability models mentioned in the DEIR are used to identify environmental impacts of this Project, and are not intended or represented to constitute environmental review for new development. CLWA did not participate in any water supply assessment for either the West Creek or the River Village projects. The Riverpark project is listed in the Los Angeles County Development Monitoring System (DMS), as are the other two mentioned development projects. The River Village project did not rely on this Project for its water supply reliability analysis. The 35,000 acre-foot Groundwater Banking Project is now final and not subject to challenge, and is a one-time 10-year storage project that cannot, because it is short-term by its nature, cause or promote growth. (See DEIR Section 6.3.3.1).
27	C-WIN	This 41,000 AF water transfer should be rejected until the EIR for the new "Monterey Plus: has been finalized and adopted. When and if you do proceed, it is required that DWR be the lead agency.	Please refer to the Master Response and to Comments 9, 10, 11 and 22 and the Responses thereto.

No.	Commenter	Comment	Response
28	C-WIN	CWN hereby incorporates all other comments by reference opposing this transfer submitted on this CLWA EIR proposing to permanently transfer 41,000 AF of Table A allocation from the Kern County Water Agency to the Castaic Lake Water Agency.	This comment is noted; no text revisions are required.
29	FSCR I	As we noted in our response to the Notice of Preparation, the Castaic Lake Water Agency (CLWA) is not the proper Lead Agency to prepare an Environmental Impact Report (EIR) for this project under the California Environmental Quality Act.	Please refer to the Master Response.
30	FSCR I	The 1995 Monterey Agreement between the California Department of Water Resources (DWR) and water contractors of the State Water Project was put in place to control transfers of the type described in the subject document. There is at present no Monterey Agreement EIR because of the PCL decision of September 2000, which held that the Monterey Agreement EIR prepared by CCWA was inadequate. The court held that the DWR was the proper Lead Agency for this Agreement because only the DWR has the statewide perspective needed to evaluate the environmental impacts to the entire water distribution system.	Please refer to the Master Response and to Comments 9, 10 and 11 and the Responses thereto. The comment incorrectly states that the 1995 Monterey Amendment was necessary to control transfers of the type specified in this Project. The 1995 Monterey Amendment had as one of its purposes to help facilitate transfers between agricultural and urban contractors, but such transfers were not prohibited prior to execution of the Monterey Amendment. The Monterey Amendment Settlement Agreement explicitly states that the SWP will operate under the Monterey Amendment while the new Monterey Amendment Program EIR is prepared. This includes operation under Article 53, pursuant to which the Kern County Water Agency consented to up to 130,000 acre-feet of agriculture to urban transfers. Suggestions that consideration of such transfers must await completion of the new Monterey Amendment Program EIR would render this element of the Monterey Amendment Settlement Agreement a nullity, contrary to the clear understanding of the signatories to that document. As the comment notes, a new Monterey Amendment Program EIR has not yet been certified, but DWR is in the process of preparing that new EIR. This comment confuses this Project and the DEIR with the Monterey Amendment and its new Program EIR. As noted in the Response to Comment 10, several transfers have occurred since the September 2000 *PCL* decision.

No.	Commenter	Comment	Response
31	FSCR I	The EIR for the 41,000 acre-feet transfer must tier from a certified Monterey Agreement EIR, which does not currently exist. This was indeed suggested by the Second Appellate District Court decision of January 2002 in the case brought against CLWA by Friends of the Santa Clara River. Page 19 of this decision states that "Respondent may be able to cure the PCL problem by awaiting action by the state DWR complying with the PCL decision, then issuing a subsequent EIR, supplement to EIR, or Addendum to EIR (Guidelines 15162, 15163, 15164) tiering on a new Monterey Agreement EIR.	Please refer to the Master Response and to Comment 10 and the Response thereto. The statement by the Court of Appeal in *Friends I* was a suggestion, not a requirement. The Court of Appeal could not have intended to require CLWA to tier off a programmatic EIR when CEQA allows a lead agency for a project to choose whether or not to tier off an available programmatic EIR. CEQA does not require a lead agency to delay a project and to wait for a programmatic EIR to become available, even where a programmatic EIR is contemplated. (See 14 Cal. Code Regs. §§ 15160 & 15168)
32	FSCR I	Since CLWA cannot legally be the Lead Agency for the subject transfer, the only legitimate way for CLWA to proceed with EIR preparation is to await DWR's preparation and certification of a Monterey Agreement EIR. The subject DEIR is thus invalid and not in compliance with court decisions involving this transfer of state water.	Please refer to the Master Response.
33	FSCR II	Please include the following correspondence between our attorney and the Department of Water Resources and their response regarding the timeline for the completion of the Monterey Agreement Environmental Impact Report. Because this EIR must be tiered on the State wide impacts addressed in the Monterey Agreement EIR and could not proceed without this Agreement, your Agency must wait until the state wide document has been certified before certifying the EIR for this project.	Please refer to the Master Response. With regard to the attached 5/18/04 letter from Alyse M. Lazar and the 6/17/04 Lester Snow DWR response thereto, please refer to the Comment 22 and the Response thereto. There is no legal requirement that this EIR be tiered off the new Monterey Amendment Program EIR. Please refer to Comment 31 and the Response thereto.
34	FSCR II	We continue to protest that you may not approve this document because you are not the correct lead agency for a project with state-wide impacts. Since the Dept. of Water Resources was found to be the legitimate lead agency for such a transfer in the decision PCL v. DWR, 2000, we protest your disregard for legal precedent on this matter. We note that your current general manager, Dan Masnada, is the same person that proceeded illegally in the above case when he was general Manager of Central Coast Water Agency. He is well aware that your agency is not proceeding according to law.	Please refer to the Master Response. The identity of the CLWA manager is irrelevant to the issue of which agency is the appropriate lead agency for the Project.

No.	Commenter	Comment	Response
35	FSCR II	Further, we wish to state that none of these documents, nor the current EIR before you address the effects of an earthquake or levee break (such as recently occurred in the Sacramento Delta, news article attached). These emergencies were also not addressed in the Urban Water Management Plan 2000. We ask that you address how your agency intends to manage such a water emergency under current water availability scenarios and how water supply would be affected under such an emergency with the additional buildout this transfer would permit.	The potential for earthquakes or levee breaks to temporarily affect water supply is noted. These issues are more appropriately addressed in the updated Urban Water Management Plan, which is scheduled for release in 2005 and requires such analysis. The EIR focuses on the environmental impacts of the transfer of Table A Amount and evaluates the water supply that would be available to CLWA using an established model developed by DWR. While emergencies could occur and temporarily disrupt water supplies, these are not impacts of the Project, and the EIR evaluates reasonable scenarios and uses the worst-case scenario in terms of growth-related impacts. SWP and CLWA facilities are designed to resist damage upon the occurrence of a seismic event. CLWA maintains substantial reservoir storage for use should SWP deliveries be temporarily interrupted from any catastrophe. The potential for seismic or other catastrophic damage significant enough to interrupt CLWA water deliveries is low, but the concern expressed in the comment is noted. Any such damage could disrupt CLWA water deliveries temporarily, but any such temporary interruption would have a less than significant impact on the DEIR projections for the long-term reliability of the Table A Amount proposed to be transferred by this Project. The Project is intended to provide an augmented water supply, over the long term, to CLWA and its purveyors. Short-term disruptions in delivering this water supply will cause inconvenience to all those reliant on CLWA's supplies. That inconvenience could occur equally today with CLWA's present sources of supply, should a catastrophic event occur. CLWA's purveyors have made provision for use of groundwater in the event CLWA deliveries are interrupted.
36	FSCR II	We ask that you respond to the recommendations made recently by the two experts, Kathy Kelly and Jonas Minton who gave testimony regarding State Water project availability before the City of Santa Clarita Planning Commission on June 29th, 2004. They both suggested that the planners should	The DEIR focuses on the environmental impacts of the transfer of Table A Amount and evaluates the water supply that would be available to CLWA using an established model developed by DWR. Three hydrologic scenarios are analyzed. The average year supply is the average amount of water available

No.	Commenter	Comment	Response
36 (cont)	FSCR II	analyze the effect of cutbacks that would be required under the worse case historical delivery rate, 13% of Title A amounts in 1991, on existing businesses and residents in the Santa Clarita Valley. Since ground water sources are in the Santa Clarita Valley are fully utilized, substantial cutbacks would be required. This significant impact should be addressed.	based on DWRSIM model results over its entire period of hydrologic record. The multiple dry year period supply is the average amount of water available over the four consecutive drought years of 1988 through 1991 based on DWRSIM model results. The single dry year supply is the supply available in the single year with the lowest total SWP deliveries based on DWRSIM model results, which occurred in 1977. In this single dry year, the supply was about 22% of Table A Amounts, and the increase in SWP supply due to the Project was estimated to be 9,200 acre-feet. If instead the supply in a single year were 13% of Table A Amounts, then the increase in supply due to the Project would be reduced to 5,300 acre-feet. Any environmental impacts based on this lower supply amount would be less than those described in the DEIR. Use of the 22% supply amount results in analysis of the worst-case environmental impact assessment scenario. The Project would have a beneficial impact to water supply, including groundwater, because it would increase the amount of water available to the CLWA service area, and would not result in a potentially significant impact. The comment implies that CLWA approves development projects. CLWA does not have the authority to approve development projects. The DEIR includes an analysis of indirect impacts of the Project, focusing on growth-related impacts, but CLWA defers to the local agencies with land use authority to conduct site-specific and project-specific CEQA review of proposed development projects. Please refer to the response to Comment 26. The comment states incorrectly and includes no evidence that groundwater sources in the Santa Clarita Valley are fully utilized. As Section 3.15.1.3 of the DEIR indicates, at Page 3.15-18, average annual production from the Alluvial Aquifer is approximately 30,000 acre-feet, within or below the 30,000-40,000 acre feet per annum operational yield. In addition, Page 3.15-19 indicates that average annual production from the

No.	Commenter	Comment	Response
36 (cont)	FSCR II		Saugus Formation is 6,800 acre-feet, well below a conservative estimate of the operational yield at 15,000 acre-feet per annum. Those yields factor in the increased groundwater pumping that occurs in dry years, given the amount of State Project water available under the Project as calculated using DWR reliability studies. (See DEIR Table 3.15-7) The projected average water demand will be less than the projected water supply available for the foreseeable future. (See Table A-1 in Attachment A to Volume II of the FEIR) Thus, the DEIR indicates that groundwater use will not increase above average operational yield even with increased dependence on State Project water. As DEIR Section 3.15.1.3 notes, the prior importation of State Project water has increased the yield of the Alluvial Aquifer as a result of return flows. Thus, increased importation under the Project potentially could increase groundwater yields. The comment provides no evidence of a significant environmental impact on groundwater resources as a result of the Project.
37	PCL/CPA	This letter provides comments on the Draft EIR entitled *Supplemental Water Project Transfer of 41,000 Acre-Feet of State Water Project Table A Amount*, on behalf of the Planning and Conservation League (PCL) and the Citizens Planning Association of Santa Barbara County (CPA). If finalized, that transfer would be the largest permanent agriculture-to-urban transfer under article 53 of the Monterey Amendments, with major implications for water resources and land use planning in Southern California. The environmental impacts of these amendments, including the instant transfer, remain to be addressed in DWR's pending "Monterey Plus" EIR review. The scoping comments submitted for that review (attached as Exhibit 1), including those of PCL, should be studied in connection with the present EIR review.	This comment is noted. Please refer to the Master Response. The commenter correctly identifies the Project as a large permanent transfer of SWP Table A Amount. However, the comment incorrectly implies that the new Monterey Amendment Program EIR will evaluate the specific environmental impacts of this Project. The Monterey Amendment Settlement Agreement provides that this Project is subject to the jurisdiction of the *Friends I* trial court, which court has ordered that CLWA certify a new EIR for this Project. The Monterey Amendment Settlement Agreement provides that the new Monterey Amendment Program EIR must analyze the environmental impacts of this Project and other transfers as they relate to the environmental impacts of approving the Monterey Amendment. The upcoming Monterey Amendment EIR will not analyze the local Project-related growth-inducing impacts in the same degree of detail for the CLWA service area, although the Monterey Amendment EIR will include the 41,000

No.	Commenter	Comment	Response
37 (cont)	PCL/CPA		acre-feet transfer in its analysis together with all other transfers of Table A Amounts. The DEIR analyzes the potential indirect environmental impacts of the Project, arising out of growth that may be served by this water supply, taking into account pre-Monterey Amendment baseline conditions, including those for agricultural State Project water. (See DEIR 3.0) The DEIR analyzes the Project impacts both with and without the Monterey Amendment. (See DEIR 3.15.2.2 & Table 3.15-5) As set forth in the Master Response, the choice of lead agency is not dictated by the size of the project, but by which agency has principal responsibility to approve and carry out the Project. Also, as described in the Master Response, CLWA, as the local agency principally approving and implementing the Project, not DWR, has more expertise and perspective to explore the implications for water resources and land use planning within CLWA's jurisdiction.
38	PCL/CPA	PCL and CPA were among the plaintiffs whose successful CEQA challenge set aside the Central Coast Water Authority's original 1995 Monterey Program EIR. That ruling led to decertification of the predecessor EIR for Castaic's transfer, which unlawfully relied upon that defective analysis. The instant Draft EIR, prepared by the same firm (SAIC) as the decertified Monterey EIR, provides a case of history repeating itself. It is legally insufficient in process and substance, failing Castaic's duty under CEQA to properly inform decision-makers and the public of the project's environmental consequences. The Draft EIR cannot be reconciled with the Monterey Amendments court decision (*Planning and Conservation League v. Department of Water Resources* (2000) 83 Cal.App.4th 892) and the settlement agreement later reached in that case. (The full Settlement Agreement appears on DWR's website at http://www.montereyamendments.water.ca.gov/.)	Please refer to the Master Response. The decertified Monterey Amendment EIR analyzed the potential environmental impacts of major amendments to the SWP contracts, with statewide implications. The "project" to be analyzed in the new Monterey Amendment Program EIR will differ significantly from the Project in this DEIR. This DEIR analyzes the potential environmental impacts of a local project. The lead agency and water supply reliability issues identified in *PCL* as not having been adequately analyzed in the decertified Monterey Amendment EIR, have been addressed in this DEIR to the extent those issues are relevant to the Project. In any event, the identity of the firm preparing the EIR is not relevant in establishing the issue of the adequacy of an EIR. The comment points to no substantive evidence of the inadequacy of the DEIR in support of its statement that the DEIR is insufficient in process and substance and fails CLWA's duty under CEQA.

No.	Commenter	Comment	Response
39	PCL/CPA	PCL and CPA submitted a comment letter on August 22, 2004. This letter, attached as exhibit 1, addressed both the instant transfer and a related proposal to transfer 16,000 acre-feet of Table A amounts from another of the Kern County Water Agency's member districts. PCL urged Castaic that it should "refrain from moving forward with these separate project reviews, which are premature and likely to operate at cross-purposes with DWR's statewide review" of the project referenced in the Monterey Amendments case settlement. PCL and CPA advised Castaic that if it prematurely attempted to proceed with separate EIRs on these permanent transfers, it would "lack the institutional authority and statewide accountability" to serve as CEQA lead agency. The DEIR simply ignores PCL's comments, and sidesteps similar ones made by other organizations.	Please refer to the Master Response and to Comments 2, 3, 5, 6 and 22 and the Responses thereto. The DEIR does not include an analysis of a 16,000 acre-foot transfer of Table A Amount as part of the Project because any such future transfer is speculative and is not linked to the Project. However, the DEIR does discuss the cumulative impacts of the 16,000 acre foot transfer in DEIR Section 6.3.3.1. CLWA issued an NOP for the 16,000 acre-foot transfer, but because the option agreement for the 16,000 acre-foot acquisition expired, CLWA has conducted no further environmental review. DWR's new Monterey Amendment Program EIR will not constitute an EIR for this Project. The Monterey Amendment Program EIR will analyze the potential impacts resulting from this Project and other transfers as they relate to potential environmental impacts of approving the Monterey Amendment. CEQA does not require that a lead agency delay a project to await a program EIR that will discuss the project as part of a broader analysis of similar projects. CEQA gives agencies the choice to prepare a project EIR in lieu of tiering off a program EIR. As the parties to the Monterey Amendment Settlement Agreement recognized, a transfer between two State Contractors is not a project for which DWR should be the lead agency. The EIR for this Project is being prepared by CLWA under the supervision and at the direction of the Los Angeles Superior Court. DWR does not have principal responsibility to approve or carry out the Project, and is acting as a responsible agency. The physical environmental impacts of a two party transfer are generally confined to the respective service areas of the two agencies involved (CLWA and WRMWSD, as a member agency of KCWA), although the DEIR analyzes potential impacts upon SWP facilities as well.

No.	Commenter	Comment	Response
40	PCL/CPA	PCL filed similar comment letters on several local projects contesting Castaic's improper and premature reliance on the 41,000 acre-feet transfer as an integral part of its reliable water supply. These comments (addressing, respectively, the West Creek Project, the River Village Project, and the Riverpark project) are attached as exhibits 2-4. They raise important questions affecting the adequacy of this EIS, as well as the prospect of possible cumulative impacts not addressed in Castaic's draft.	Please refer to the Response to Comment 26.
41	PCL/CPA	Castaic's so-called "stand-alone" Draft EIR is fraught with potential for inconsistency with DWR's upcoming environmental review and decision on the "Monterey Plus" project. That review will address the identical transfer from a statewide perspective, with an integrated analysis of that project in its entirety. Castaic lacks the expertise and authority to proceed based upon its isolated assessment of project impacts, alternatives, and mitigation, each of which may well be undermined by DWR's subsequent analysis and decision.	Please refer to the Master Response and to Comments 2 through 6 and the Responses thereto. The comment incorrectly suggests that the new Monterey Amendment Program EIR will address this Project in its entirety with an integrated analysis. The Los Angeles Superior Court in *Friends I* ordered CLWA, not DWR, to prepare the EIR for this Project. The Monterey Amendment Settlement Agreement requires DWR to prepare a new program EIR for the Monterey Amendment, not for this Project. The Monterey Amendment Settlement Agreement excludes the possibility that the new Monterey Amendment Program EIR could constitute an EIR for this Project because it states that the Los Angeles Superior Court retains jurisdiction over the environmental document for this Project. The Monterey Amendment Settlement Agreement only requires that DWR analyze the potential impacts resulting from this Project and other transfers as they relate to the potential environmental impacts of approving the Monterey Amendment. Attachment D of the Monterey Amendment Settlement Agreement recognizes that non-final individual transfer projects will be reviewed by DWR only as the responsible agency. There is no evidence that this DEIR will be undermined by DWR's new Monterey Amendment Program EIR. Both this DEIR and the Monterey Amendment DEIR use the same DWR model (CALSIM II) to evaluate potential impacts, and CLWA

No.	Commenter	Comment	Response
41 (cont)	PCL/CPA		has coordinated with DWR, acting as a responsible agency, to ensure that the DEIR will not undermine DWR's efforts in preparing the new EIR for the Monterey Amendment.
42	PCL/CPA	Two recent Second District Court of Appeals cases reinforce the point that Castaic Lake Water Agency (CLWA) should not pursue its own independent EIR on the 41,000 acre foot transfer in advance of the completion of DWR's tier-one "Monterey Plus" EIR. In *Friends of the Santa Clara River v. Castaic Lake Water Agency* (2002) 95 Cal.App.4th 1373, the Second District court of appeal ordered the decertification of the previous EIR Castaic prepared to support the instant transfer. The Friends group and other environmental organizations opposed the project decision on that Kern/Castaic transfer, citing environmental consequences in the Santa Clara River area and association with numerous sprawl development projects. In its CEQA assessment, the court recognized that the proposed 41,000 acre-feet transfer "is part of an overall larger scheme, analyzed on a programmatic basis in the Monterey Agreement EIR." (*Id.* at 1384.)	Please refer to the Master Response and to Comments 37, 39 and 41 and the Responses thereto. The possibility that the Project can be considered part of an overall larger scheme for purposes of tiering off a program EIR, instead of preparing a stand alone project EIR, does not mandate that the agency tier off a program EIR.
43	PCL/CPA	Another recent Second District appellate decision, *Santa Clarita Organization for Planning and the Environment (SCOPE) v, County of Los Angeles (*2003*)* 106 Cal.App.4th715, critically addressed Castaic's characterization of the 41,000 acre-feet transfer. In that case, the County of Los Angeles violated CEQA in its review of the West Creek development project that erroneously assumed that 100 per cent of Castaic's purported 41,000 acre-feet would be available in wet years and 50 per cent in drought years. Drawing on *Planning and Conservation League's* assessment of the historic disparity between Table A amounts and deliverable water, the court concluded that the EIR failed to undertake a "serious and detailed analysis" of State Water Project supplies, and observed that "[t]he dream of water entitlements for the incomplete State Water Project is no substitute for the reality of actual water the SWP can deliver." (*Id.* at pp. 723, 717.)	This comment is noted, but it is inapplicable to the DEIR. It is not a comment on the Supplemental Water Project EIR. The project that was the subject of the *SCOPE* litigation and EIR is distinguishable from this Project. In *SCOPE*, the EIR for a development project[1] was invalidated because its cumulative impacts analysis of past, present and future developments on the amount of water available relied heavily on SWP Table A Amounts in calculating the total available water supply. The EIR in *SCOPE* made no attempt to calculate or even discuss the differences between Table A Amounts and actual supply. The EIR in *SCOPE* did not contain estimates or past delivery history from DWR, the agency that manages the SWP, in projecting how much water the SWP can deliver in different types of years.

No.	Commenter	Comment	Response
43 (cont)	PCL/CPA		In contrast, this DEIR does not analyze a development project, but a transfer of SWP Table A Amount. CLWA's acquisition of an additional 41,000 acre-feet Table A Amount serves to firm up CLWA's SWP deliveries to meet CLWA's current demand and to help meet future demand projected in local land use agency planning documents. The DEIR for this Project contains a detailed calculation of the total available water supply and discusses in detail the differences between Table A Amounts and actual supply. The DEIR for this Project contains DWR reliability estimates using DWR models as to how much water DWR can deliver in different types of years. The DEIR in Section 1.1 also cautions any land use agencies intending to rely on the Project for a water supply for new development that "past water deliveries are not a guarantee of future water delivery rates." [1] *The EIR in SCOPE was not prepared by Castaic as suggested in the comment – CLWA does not approve development projects.*
44	PCL/CPA	The Courts have also emphasized that DWR must act as lead agency in performing Tier 1 environmental studies. If Castaic continues with its separate environmental reviews without awaiting DWR's assessment in the "Monterey Plus" EIR, it would violate CEQA's lead agency requirement based upon the well-established standards set forth in *Planning and Conservation League v. Department of Water Resources*. The court in that case could hardly have been clearer that *DWR* is the "state agency charged with the statewide responsibility to build, maintain, and operate" the State Water Project. (*Id.* at p. 906.; see also Wat. Code, §12930, *et seq.*) Finding that DWR was the only entity with the requisite statewide perspective and expertise to serve as lead agency, the court found it "incongruous to assert that any of the regional contractors" could "assume DWR's principal responsibility for managing the SWP." (*Id.*) The court-approved settlement agreement in *Planning and Conservation League* recognizes DWR's duty as "the	Please refer to the Master Response and to Comments 2, 3, 4, 5, 6, 8, 9, 10, 22 and 72 and the Responses thereto. The DEIR is not a Tier 1 environmental study. The Project does not encompass administering, building, maintaining, managing and operating the SWP. DWR's role in the Project is as a responsible agency, charged with responsibility of approval of a point of delivery agreement to facilitate the transfer. The Monterey Amendment Settlement Agreement recognizes the role of State Water Project contractors as lead agencies for two party transfers between contractors. The Monterey Amendment Settlement Agreement provides that the Monterey Amendment will remain in place during preparation of the new Monterey Amendment Program EIR, thus permitting contractor transfers of the 130,000 acre-feet identified in Section 53 the Monterey Amendment. CLWA, not DWR, has local expertise regarding anticipated future projects within CLWA for indirect and cumulative impacts analysis. DWR's statewide authority and experience has been utilized, to the extent appropriate, in evaluating the Project's potential environmental

No.	Commenter	Comment	Response
44 (cont)	PCL/CPA	State agency responsible for administration and operation of the SWP," as well as its continuing obligation to comply with applicable requirements of CEQA and the Water Code. (Settlement Agreement, Section X.B.) The transfer guidelines disclosed to contractors under the settlement agreement also recognize the continuing need to comply with all existing legal requirements, including CEQA, and to honor the lead agency principles identified in the Third District's decision in the Monterey Amendments case (see http://ceres.ca.gov/ceqa/cases/2000/PCLvDWR-2000.html). These principles apply clearly to the proposed permanent transfers of the Table A amounts referenced in the state project contracts, which require DWR's approval and presuppose the application of Monterey. They also concededly require changes in the amount of supplies available to several water agencies, the location and timing of project deliveries, and changed utilization of the project's conveyance and storage facilities. The transfers, which may require the fallowing of farmland in agricultural areas outside the jurisdiction of CLWA and are associated with proposed annexations linked to some of the more controversial development projects in California, demand the statewide authority and experience that only DWR can provide.	impacts, in that DWR has been consulted as a responsible agency. DWR's new Monterey Amendment Program EIR will not analyze the Project in its entirety. According to the Monterey Amendment Settlement Agreement, DWR will only analyze the potential environmental impacts resulting from this Project and other transfers as they relate to the potential environmental impacts of approving the Monterey Amendment. Oversight of the CEQA analysis for the Project falls within the jurisdiction of the Los Angeles Superior Court, as stated in the decision in the *Friends I* case and as acknowledged by the Monterey Amendment Settlement Agreement, Section III(E). There is no evidence that this DEIR will violate DWR's lead agency status in the preparation of the new Monterey Amendment Program EIR. The Monterey Amendment project description is substantially different from the description for the Project. The two environmental analyses share one common feature--both this DEIR and the Monterey Amendment EIR use the same DWR model (CALSIM II) to evaluate potential impacts. The Project does not require the fallowing of farmland and is not linked to any development project. Please refer to the Response to Comment 72 for a thorough discussion regarding the lack of need for fallowing resulting from the Project. Please also refer to the Responses to Comments 23 and 26.
45	PCL/CPA	Lastly, Castaic's hypothetical "non-Monterey" analysis of the transfers in the Draft EIR cannot substitute for DWR's new assessment of the Monterey changes. In *Friends*, Castaic unsuccessfully attempted to portray its transfer EIR as capable of standing alone, outside the Monterey Amendments program. Although transfers were available under Article 41 of the pre-Monterey State Water Project contracts subject to express DWR approval, DWR has neither reviewed nor conferred approval on the present transfer under Article 41.	Please refer to the Master Response and to Comments 3, 5 and 10 and the Responses thereto. As those comments from DWR note, DWR has approved of the DEIR's "non-Monterey" analysis. The *Friends I* court rejected CLWA's claim that the prior Project EIR stood alone because the prior Project EIR did not analyze the environmental impacts on the seller's lands under pre-Monterey Amendment conditions. However, the DEIR does analyze those impacts, as set forth in DEIR Section 3.2 and Appendix C. Therefore, the "straw man" problem of

No.	Commenter	Comment	Response
45 (cont)	PCL/CPA	Moreover, it is highly speculative whether agriculture-to-urban transfers such as the 41,000 acre foot transfer would even have taken place without the Monterey Amendments, since those Table A amounts would have been subject to "agriculture first" cutbacks under pre-Monterey article 18(a). Read in context, such maneuvers would amount to little more than the "straw man" argument considered and rejected in the *Friends* appeal. (95 Cal.App. 4th at p. 1387.)	referencing the Belridge EIR that did not address the impacts to the seller's lands, discussed in *Friends I*, has been resolved in the DEIR. To clarify, the Project could occur either pre- or post-Monterey Amendment and has been analyzed accordingly in this "stand alone" DEIR. The commenter fails to acknowledge that the Monterey Amendment Settlement Agreement provides that the Monterey Amendment remains in full force and effect, and that permanent Table A Amount transfers may occur under the Monterey Amendment, while DWR prepares the new Monterey Amendment EIR. As noted in DEIR Section 1.4.2, CLWA has 12,700 acre-feet of SWP agricultural contractor water previously purchased under the pre-Monterey Amendment condition. DEIR Table 3.15-17 illustrates that CLWA would obtain more of an advantage from the Project under imposition of pre-Monterey Amendment Article 18(b) in average and multiple dry years than it would under the Monterey Amendment. Therefore, the Project is potentially advantageous to CLWA even without the Monterey Amendment. That is because the remaining 41,500 of CLWA's 54,200 Table A Amount pre-existing the Project is designated as M&I contractor water and would benefit in years when agricultural contractor cutbacks would occur under pre-Monterey Article 18(b).
46	PCL/CPA	The instant Draft EIR, includes glaring errors. A piecemeal and startlingly inaccurate description of the Monterey case Settlement Agreement (ES 2-4) fails even to inform the reader that DWR's statewide review of the "Monterey Plus" project could affect the future of this transfer or of the Monterey Amendments themselves.	The description of the Settlement Agreement is accurate and contains the specific information relevant to the EIR analysis. Because the new Monterey Amendment EIR is still in preparation, the Supplemental Water Project EIR contains an analysis of environmental impacts that would occur both with and without the Monterey Amendments in place, consistent with CEQA Guidelines section 15144, which indicates that "while foreseeing the unforeseeable is not possible, an agency must use its best efforts to find out and disclose all it can." Trying to forecast what future changes to SWP Contracts might occur as a result of the new Monterey Amendment EIR, and

No.	Commenter	Comment	Response
46 (cont)	PCL/CPA		what the environmental impacts of such changes would be, is speculative and not required by CEQA (CEQA Guidelines section 15145). Because the Monterey Amendment Settlement Agreement provides that the Monterey Amendment will remain in full force and effect while DWR prepares a new EIR, it is appropriate that the environmental analysis for this Project include both the "with and without Monterey Amendment" conditions. The September 24, 2002 trial court judgment on remand in *Friends I* provided as follows with respect to the water transfer under this Project pending certification of an EIR that complies with CEQA and the Court of Appeal opinion: "Respondent will not be prohibited from using the water to which it is entitled, but petitioner may renew its application for such prohibition based upon evidence of the actual use of such additional water for purposes it considers improper." The Court of Appeal affirmed that judgment in a subsequent unpublished opinion. Please refer to the Master Response and to Comments 2-6 and the Responses thereto. The DEIR is not tiered off the new Monterey Amendment Program EIR. The new Monterey Amendment Program EIR is still pending and could take many months to complete. As noted by DWR, the approach to environmental analysis in the DEIR is not inconsistent with the approach that DWR is taking in preparing the new Monterey Amendment Program EIR. DWR is a responsible agency that must approve or disapprove the Project and will rely upon CLWA's certified EIR to perform that function.
47	PCL/CPA	The "Settlement Agreement underscores the non-finality of the 41,000 acre-feet transfer and the need for DWR's statewide review. For example: • Section III.D refers to a list of transfers listed in attachment E to the agreement, which the settling parties, without specifically endorsing or opposing them, recognize as	Please refer to the Master Response and to Comments 9, 10 and 22 and the Responses thereto. The Monterey Amendment Settlement Agreement does not state or imply that the new Monterey Amendment Program EIR must serve as the EIR or as a Tier 1 EIR for this Project. Section (III)(C)(4) of the Monterey Amendment Settlement Agreement only requires that the new Monterey Amendment Program EIR analyze the

No.	Commenter	Comment	Response
47 (cont)	PCL/CPA	"final" and agree not to challenge. This transfer is *not* included in that list. • Further evidence of the non-finality of the Castaic transfer is that section III.E singles out this transfer for a special acknowledgment recognizing that it is the subject of pending litigation in this Court.[fn.1] • Section III.C.4 recognizes DWR's commitment to provide in its forthcoming statewide programmatic EIR an "[a]nalysis of the potential environmental effects" relating to "the Kern-Castaic Transfer," identifying it as one of the actions "that relate to the potential environmental impacts of approving the Monterey Amendments." [Fn. 1 from letter:] The Draft EIR erroneously attempts to recast this provision as a "specific exclusion" of this transfer from "any prohibitions against transfers of Table A amounts by the Settlement Agreement." That is simply wrong. Section III.E recognizes that this transfer is "subject to pending litigation in the Los Angeles Superior Court following remand from the Second District Court of Appeal." It reflects a recognition that "jurisdiction with respect to that litigation should remain in the [Los Angeles] court," and the settling parties' concurrence that "nothing in this settlement agreement is intended to predispose the remedies or other actions that may occur in that pending litigation."	potential environmental impact of Monterey Amendment Settlement Agreement Attachment E transfers and this Project as actions that relate to the potential environmental impacts of approving the Monterey Amendments. Section III(E) of the Monterey Amendment Settlement Agreement, which recognizes that the Los Angeles County Superior Court in *Friends I* has jurisdiction over this Project, serves to limit the analysis required by Section III(C)(4). The Los Angeles County Superior Court in *Friends I* stated in its judgment on remand with respect to this Project: "Respondent will not be prohibited from using the water to which it is entitled, but petitioner may renew its application for such prohibition based upon evidence of the actual use of such additional water for purposes it considers improper." With respect to DEIR reference to a "specific exclusion," see the Response to Comment 10.
48	PCL/CPA	DWR has recently confirmed that this transfer remains subject to the Settlement Agreement and its future "Monterey Plus" EIR. As DWR Director Lester Snow wrote on June 17, 2004 to *Friends* case lead counsel Alyse Lazar, "DWR's treatment of the transfer of Table A amounts from Kern County Water Agency to Castaic Lake Water Agency will be governed by the Settlement Agreement. As provided in Paragraph lllC4 of the Settlement Agreement, the EIR will include an "analysis of the potential environmental impacts relating to (a) the Attachment E transfers, and (b) the Kern-Castaic Transfer, in each case as	Please refer to the Master Response and to Comments 22, 33 and 47. The Snow letter does not state that the Project will be reviewed by DWR as a new project. In fact, the Snow letter reaffirms what the Settlement Agreement provides, i.e., that the Project and the Settlement Agreement Attachment E transfers will be reviewed only "as actions that relate to the potential environmental impacts of approving the Monterey Amendments."

No.	Commenter	Comment	Response
48 (cont)	PCL/CPA	actions that relate to the potential environmental impacts approving the Monterey Amendments." Section 1(0) of the Settlement Agreement defines the "Kern-Castaic Transfer" as "the transfer of 41,000 AF of water from Kern County Water Agency to the Castaic Lake Water Agency, approved by DWR on March 31, 1999." DWR has not completed any draft or final analysis regarding these transfers." Given both the required state leadership on an ongoing Tier 1 environmental study and the pending litigation, the future of the Castaic transfer and, indeed, the broader Monterey Amendments, cannot be assumed.	
49	PCL/CPA	The Draft EIR's assertion that the Settlement Agreement "did not change the substance of the Monterey Amendments" is also misleading. Although those amendments are part of the "Monterey Plus" project, the agreement also eliminates misleading references to "entitlements" from the state contracts and adds a new provision to the contracts imposing water reporting requirements. The agreement also imposes a host of other substantive changes in State Water Project operation that should be described in the Final EIR.	Section II of the Monterey Amendment Settlement Agreement authorizes the continued administration and operation of the SWP and Kern Water Bank in accordance with the Monterey Amendment and the amendment attached as Exhibit A to the Settlement Agreement. As the recitals and Section 8 of the Exhibit A amendment explains, the intent of most of the Exhibit A changes was "solely for clarification purposes" and to "not in any way change the rights, obligations or limitations on liability of the State or the District." The only other provision in the Exhibit A amendment was the addition of Article 58, which provides for biennial reporting by DWR of the delivery capability. Article 58 is a procedural, and not a substantive change. None of the Exhibit A changes or other provisions of the Settlement Agreement appear to alter the environmental impacts of the Monterey Amendment. In any event, the Monterey Amendment is an entirely different project from that analyzed in the DEIR for the Project. Under the Monterey Amendment Settlement Agreement, the Monterey Amendment remains in place, including Article 53 that provides for permanent agricultural to urban contractor transfers of 130,000 acre-feet of Table A Amounts from Kern County. This Project was a transfer that fell within that 130,000 acre-feet Table A Amount, but the Project could equally occur under Article 41 of the State Water Project contract without the Monterey Amendment in place. Section III(E) of the Settlement

No.	Commenter	Comment	Response
49 (cont)	PCL/CPA		Agreement confirms that the environmental analysis for this Project is subject to the jurisdiction of the Los Angeles County Superior Court, the venue for the *Friends I* case, and is not subject to the jurisdiction of the Sacramento County Superior Court, the venue for the challenge to the prior Monterey Amendment Program EIR.
50	PCL/CPA	Castaic's refusal to await DWR's "Monterey Plus" EIR would fatally compromise its ability to identify alternatives to the proposed transfer that might maximize its benefits and minimize its environmental impacts statewide prior to rendering the transfer a *fait accompli*. DWR's EIR will programmatically address Castaic's transfer in the context of statewide contract amendments. A major issue requiring assessment in that document will be the possible *alternative* dispositions of the 41,000 acre feet of Table A amounts to serve other uses. To list several possible examples, the alternative uses subject to statewide analysis might include ecological restoration, urban infill development in Los Angeles or San Diego, and relief from cutbacks of Colorado River deliveries in excess of the California's 4.4 million acre-feet in annual entitlement. (See *Arizona v. California* (1964) 376 U.S. 340 (Colorado River); fn. 7, *supra* p. 16).) In short, legally adequate assessment of these issues under CEQA will require DWR's "statewide perspective" rather than the provincial experience of a local water agency, and demands recognition that this transfer is an overall part of the Monterey program. (*Friends I*, 95 Cal.App.4th at p. 1384.)	Please refer to the Master Response. The comment misconstrues what the Monterey Amendment Settlement Agreement states regarding analysis of the Project in DWR's new Monterey Amendment Program DEIR. Section III(C)(4) of the Monterey Amendment Settlement Agreement states that DWR will analyze the potential environmental impacts of the Project as they relate to the potential environmental impacts of approving the Monterey Amendment. Thus, DWR's analysis of the Project in the new Monterey Amendment Program DEIR will be included as part of a broader analysis of past and future permanent transfers of Table A Amounts. But DWR's analysis of the Project impacts will not constitute the EIR for the Project and is not required to serve as a Tier 1 EIR for the Project. Section III(E) of the Monterey Amendment Settlement Agreement, which recognizes that the Los Angeles County Superior Court in *Friends* I has jurisdiction over this Project, serves to limit the analysis required by Section III(C)(4). The comment appears to confuse the appropriate environmental analysis of the Monterey Amendment with the appropriate analysis of the Project that is the subject of the DEIR. An EIR need only consider alternatives to the project described and analyzed in that EIR. The Court of Appeal in *Friends I* ordered the environmental review for the Project to be conducted by CLWA under the jurisdiction of the Los Angeles Superior Court. The Monterey Amendment Settlement Agreement acknowledges the jurisdiction of that court over the EIR for this Project. The alternatives suggested for analysis by this commenter are more appropriate suggestions for consideration in DWR's preparation of the DEIR for the Monterey Amendment, to the extent that the alternatives are

No.	Commenter	Comment	Response
50 (cont)	PCL/CPA		feasible or acceptable. None of the alternatives suggested by the commenter fit within the criteria for alternatives to the Project. None of the suggested alternatives would feasibly attain most of the basic objectives of the Project as required by CEQA. The objectives of the Project are to augment CLWA's Table A Amount to meet the water demands of existing users and anticipated future growth and to provide a means of delivery for the augmented water supplies. The DEIR includes analysis of a "No Project" alternative and a reasonable range of alternatives that will foster informed decision-making and public participation, including those alternatives that would feasibly attain most of the basic objectives of the Project but would avoid or substantially lessen any of the significant effects of the Project. As noted elsewhere in these responses to comments, DWR has provided its statewide perspective to the DEIR in DWR's role as a responsible agency. DWR is charged with analyzing the potential environmental impacts of the Project and other transfers as they relate to the potential environmental impacts of approving the Monterey Amendment because DWR has agreed to prepare its new Monterey Amendment Program EIR in accordance with the provisions of the Monterey Amendment Settlement Agreement.
51a	PCL/CPA	The Draft EIR's water supply assessment (especially in sections 3.15 and Appendix D) make highly problematic assumptions about state water reliability,	Please refer to response to comment 25.
51b	PCL/CPA	as well as the availability of "surplus" water under Article 21 of the state project contracts.	SWP surplus water is SWP water that can be made available to Contractors when water and capacity are available in excess of SWP storage needs and Table A supplies. The different types of surplus water, and surplus water terminology, both with and without the Monterey Amendment are described in Table A-2 of Attachment A to Volume II of the FEIR. This table is a sub-set of Table 3.15-3 on page 3.15-8 of the DEIR. The uses of surplus water in the DEIR's water supply assessment are described below for each category of surplus water. As described below, the assumptions for surplus water

No.	Commenter	Comment	Response
51b (cont)	PCL/CPA		made in the water supply assessment are consistent with the SWP Contracts, SWP operations and the availability of surplus water, and both WRMWSD's and CLWA's ability to take delivery of surplus waters. **Scheduled Surplus Water** Scheduled surplus water was included only in the With Article 18(b) Implemented allocation scenario. It was included in this scenario because with the reduction in Table A Amounts under that scenario, scheduled surplus water would have been available on a scheduled or more dependable basis similar to Table A supplies (i.e., Contractors could schedule deliveries of scheduled surplus water in advance, in a manner similar to their annual Table A requests). Because the overall availability of SWP supply is independent of the way water is allocated among Contractors, it was assumed that the SWP supply would remain the same under this scenario. However, because total Table A Amounts would be proportionally reduced to the "minimum project yield," there would be frequent occasions when water above this minimum project yield amount would be available as part of allocated supplies. For example, if DWR anticipates the available SWP supply to be 3.0 MAF in a particular year, and if all Contractors' Table A Amounts were reduced to a hypothetical new minimum project yield of 2.0 MAF, then the 1.0 MAF of available SWP supply above that minimum project yield could be scheduled, in advance, for delivery to Contractors similar to Table A supplies. This is consistent with the SWP Contracts, SWP operations and the availability of surplus water, and both WRMWSD's and CLWA's ability to take delivery of this water. Scheduled surplus water is assumed to be unavailable under the Without Monterey Amendment and With Monterey Amendment allocation scenarios because (1) for the Without Monterey Amendment allocation scenario, scheduled surplus water was generally available only during the early years of the

No.	Commenter	Comment	Response
51b (cont)	PCL/CPA		SWP, when total Contractor demands were low, and has not been available since the mid-1980s due primarily to increasing Contractor demands for Table A supplies, and (2) for the With Monterey Amendment allocation scenario, the category of scheduled surplus water was eliminated as part of the Monterey Amendment. This is consistent with the SWP Contracts, SWP operations and the availability of surplus water, and both WRMWSD's and CLWA's operations and facilities. **Unscheduled Surplus Water and Article 21 Water** As described on page 3.15-36 lines 33-40, unscheduled surplus water/Article 21 water was not included in the water supply analysis for any of the three water allocation scenarios. This was because unscheduled surplus water/Article 21 water is not available on a routine or predictable basis, and is generally only available for short periods of time during low demand months when most Contractors have a limited ability to use it. While unscheduled surplus water/Article 21 water is available under the SWP Contracts and SWP operations, it is only periodically and temporarily available and is not a reliable supply. Not including this water is consistent with WRMWSD's and CLWA's operations and facilities because both agencies have limited capacity to take delivery of this water when it is available (as compared to a few other SWP Contractors that have large surface and/or groundwater storage facilities and can take delivery of large amounts of unscheduled surplus water/Article 21 water when it is available and store the water for future use).
51c	PCL/CPA	DWR's record of deliveries to contractors under the SWP figured centrally in the Third District's conclusion that the 1995 EIR must be set aside. (See *PCL v. DWR*, 83 Cal. App. 4th at 908 (noting the "huge gap between what is promised and what can be delivered" and that "actual, reliable water supply" is "in the vicinity of 2 to 2.5 MAF of water annually" rather than the 4.23 MAF of Table A "entitlements"); 83 Cal. App. 4th at 913	CLWA has obtained and included in the DEIR a frank assessment of DWR's record of deliveries. In the DEIR, CLWA shows a record of historic SWP deliveries for 1990 through at least 2001, showing total SWP deliveries, SWP deliveries to WRMWSD, and SWP deliveries to CLWA (see Tables 3.15-2, 3.15-5, and 3.15-8, respectively). In addition to showing actual acre-feet of deliveries, these tables show the SWP allocation

No.	Commenter	Comment	Response
51c (cont)	PCL/CPA	(average actual deliveries under the SWP from 1980-1993 "were around 2.0 MAF"). A frank assessment of DWR's record of deliveries is essential to a wide variety of issues addressed in the EIR, including the no project alternative as well as the assessment of hydrologic impacts, land use and planning impacts, growth-inducing impacts, and cumulative impacts. Anticipating the importance of this issue, the Monterey Settlement Agreement required periodic SWP reporting on the reliability of SWP deliveries.	percentage for each year. These allocation percentages show the percentage of Contractors' requested Table A Amounts the SWP was able to meet. For example, while total SWP deliveries appear low in 1998, the allocation of 100 percent indicates that Contractors' SWP requests were completely met. Low deliveries that year were due to 1998 being a very wet year, which reduced Contractor demands for SWP water. Therefore, the low deliveries in 1998 were limited by demand, not by supply. In 2001, total SWP deliveries were only slightly less than in 1998. However, the allocation percentage that year was only 39 percent, indicating that SWP supplies were only able to meet 39 percent of Contractors' requested Table A Amounts. Clearly, the low SWP deliveries in 2001 were constrained by the amount of available supply. The *PCL* and *SCOPE* cases (*Planning & Conservation League v. Department of Water Resources* [2000] 83 Cal.App.4th 892 and *Santa Clarita Organization for Planning the Environment v. County of Los Angeles* [2003] 106 Cal.App.4th 715) do not require CLWA to prepare a study or model independent of DWR studies and models. Several commenters on the SWP Delivery Reliability Report questioned the reliability estimates in the report, based in part on the argument that historic deliveries were much lower than the report's estimates. However, at least one of these commenters (Dennis O'Connor) acknowledges in his comments that "while many try to compare the modeled 2001 reliability against historic SWP operations, it is not really appropriate for much of the period" (O'Connor 2002). This is because Contractors' contractual Table A Amounts and requests for SWP water were in a build-up phase during much of this period. Table A Amounts, which limit how much SWP water a Contractor may request, reached a maximum in 1990 for most Contractors; and delivery requests for most Contractors have only recently increased up to their Table A Amounts. In addition, the regulatory rules governing the Delta and SWP

No.	Commenter	Comment	Response
51c (cont)	PCL/CPA		operations have become more stringent over the years, with most of the current rules issued in 1995. Therefore, as O'Connor notes in his comments, "comparing modeled 2001 reliability against actual deliveries is somewhat misleading much beyond the last few years" (O'Connor 2002). DWR has responded to the comments of O'Connor and others on this issue (see letter from DWR to Senator Michael Machado dated March 11, 2003; DWR 2003c). In addition to providing information on historic SWP deliveries, the DEIR includes a detailed analysis of indirect and growth-related impacts of the Project (see Chapter 5). The DEIR also provides a summary of the effects of the Project with regard to local and regional Plans and Policies (see DEIR Chapter 4).
51d	PCL/CPA	The Draft EIR uses dubious modeling assumptions to claim an average of annual deliveries exceeding the historical record by approximately a million acre-feet. (See DEIR, 3.15-7.)	Please refer to Responses to Comments 25 and 51c.
51e	PCL/CPA	In part, Castaic's EIR relies upon dated studies employing an outmoded model (DWRSIM).	The differences between DWRSIM and CALSIM II model study results were considered and found to be so minimal as to not result in changes to the environmental impact determinations in this DEIR. Moreover, use of the slightly higher SWP supplies associated with the use of DWRSIM resulted in DEIR consideration of the worst-case scenario; i.e., the scenario that would result in greater direct and indirect impacts in both the CLWA and WRMWSD service areas. Direct impacts would remain less than significant regardless of the modeling tool used, and indirect impacts from growth-related development would remain significant regardless of the modeling tool used. No new environmental impacts would result from the use of CALSIM II instead of DWRSIM. As described on page 3.0-5 line 10 through page 3.0-6 line 27, page 3.15-31 line 15 through page 3.15-32 line 2, in Appendix D section 2, and in Responses to Comments 4 and 25, the environmental impact analysis was conducted using DWRSIM because these studies were consistent with the 1998 "pre-

No.	Commenter	Comment	Response
51e (cont)	PCL/CPA		Project" environmental setting used in the DEIR. Additionally, at the time the analysis was conducted for the DEIR, the DWRSIM studies from the CALFED Bay-Delta Program EIS/EIR provided the best available estimates of SWP deliveries, and were the most comprehensive, well-established, publicly available model studies available. The two DWRSIM studies used received extensive public and technical review as part of the CALFED process and formed the basis for the SWP and CVP water supply analysis for the CALFED Bay-Delta Program EIS/EIR. Once DWR released the CALSIM II studies conducted for DWR's SWP Delivery Reliability Report, the SWP deliveries from these studies were compared with the results from the DWRSIM studies used for this DEIR. While the modeling tool itself has changed, the criteria used in the models to simulate SWP operations have not significantly changed. The delivery results of DWR's more recent assessment of SWP reliability in its SWP Delivery Reliability Report using CALSIM II are comparable to the results of the DWRSIM studies (see Table A-3 of Attachment A to Volume II of the FEIR and Appendix D of the DEIR, Section 2.2 for a comparison of these model study results). As shown in Table 3, the results of the two modeling studies are similar; however, in general, the estimates of SWP supplies associated with the 41,000 AF of Table A Amount based on the SWP Delivery Reliability Report and CALSIM II are somewhat lower than the amounts under the DWRSIM studies for the comparable allocation scenario. Therefore, from an environmental impact assessment standpoint, the DEIR analyzed the worst-case scenario; i.e., the scenario that would result in greater direct and indirect impacts in both the CLWA and WRMWSD service areas. The reasons for these differences were discussed in the DEIR on page 3.15-31 line 29 through page 3.15-32 line 2 and are briefly summarized below: • The results in this EIR account for the variable demand used by DWR in its model studies (consistent with the way DWR actually has allocated water), while the results

No.	Commenter	Comment	Response
51e (cont)	PCL/CPA		as presented in DWR's delivery reliability report do not (i.e., in DWR's report, deliveries are presented as a percentage of Table A, regardless of the lower demands used in some years of the study); and, • The "existing" case in this EIR is based on 1998 SWP demand conditions, while the "existing" case in DWR's report is based on higher 2001 SWP demand conditions. The 2001 total SWP demand is higher than the 1998 demand due to increased M&I Contractor demands. A higher total demand can result in some years in less water being allocated to the same Table A Amount, so the higher 2001 demand results in a slightly lower quantity of water associated with the 41,000 AF of Table A Amount.
51f	PCL/CPA	To move beyond DWRSIM's obvious deficiencies, the Draft EIR also makes unwarranted extrapolations from DWR's 2003 reliability report.	The commenter refers to "unwarranted extrapolations from DWR's 2003 reliability report," but provides no further information regarding any specific "extrapolations" or what is "unwarranted." As discussed in more detail in Response to Comment 25, the SWP Delivery Reliability Report was used in the DEIR only to estimate SWP supplies for the current environmental setting. The pre-project 1998 environmental baseline and the project environmental impact analyses were based on separate model studies (DWRSIM model studies conducted by DWR for the CALFED Bay-Delta Program EIS/EIR), and not on model studies from the SWP Delivery Reliability Report. While the derivation of supply estimates in the DEIR for the current environmental setting is based on data from the SWP Delivery Reliability Report, the derivation method used is straightforward and was performed just as suggested by DWR in that report. In that report, DWR presents the probability of being able to meet total SWP deliveries as a percent of full Table A Amounts. DWR suggests that this information can be directly applied to individual Contractors by multiplying the total delivery percentages by an individual Contractor's Table A Amount. In the DEIR, supply estimates were derived for

No.	Commenter	Comment	Response
51f (cont)	PCL/CPA		three hydrologic conditions. Estimates of total SWP supplies under each of these hydrologic conditions were taken directly from Table B-3 of DWR's SWP Delivery Reliability Report. The delivery percentage under these conditions were determined by dividing these total SWP deliveries by total Table A Amounts of 4.133 million AF, and CLWA's share of that supply was determined by multiplying this percentage by CLWA's Table A Amount of 95,200 AF. For example, the average supply available to CLWA was estimated by starting with the average total SWP supply from DWR's Table B-3, which is 2.962 million AF. Dividing this supply by the total Table A Amounts of 4.133 million AF results in a delivery percentage of 71.7 percent. Multiplying this percentage by CLWA's Table A Amount of 95,200 AF results in an estimated average supply to CLWA of 68,300 AF. Supply estimates for the hydrologic conditions based on specific hydrologic years were derived in the same manner, starting with total SWP deliveries from DWR's Table B-3 for those specific years. These limited extrapolations, which were conducted just as suggested by DWR, are not "unwarranted." None of the environmental impact analyses performed for the DEIR were based on the particular data that were derived from the SWP Delivery Reliability Report.
51g	PCL/CPA	That report has faced significant controversy regarding its overall conclusions and the computer modeling that underpins its reliability projections. For instance, the reliability report constructs delivery probability charts for the SWP for two years, 2001 and 2021. As noted by several commenters, the median delivery identified in the report (3.297 MAF) is on the order of 50% greater than the actual record of historic deliveries to the SWP as reported by DWR. A detailed analysis by Dennis O'Connor for the California Research Bureau, referenced in the comment letter of Senator Machado [fn2], indicates that the draft reliability report provides no credible explanation for this disparity. O'Connor's analysis concludes that among other problems, the results are inconsistent with previous estimates	Please refer to Response to Comment 25.

No.	Commenter	Comment	Response
51g (cont)	PCL/CPA	and models, recent deliveries were lower than the modeled 2001 conditions, and 2021 does not reflect any growth in upstream consumptive use. His assessment also observes that CALSIM II is not calibrated or otherwise verified, and that the draft reliability report does not use the CALSIM II model as designed. Because the draft reliability report appears to overstate the supply reliability of the SWP, O'Connor's analysis warns that DWR's assessments of reliability should not replace the "paper water" problem with a new, simulation-based "cyber water" problem. Other comment letters, notably those of Robert C. Wilkinson, Peter Gleick, and Arve Sjovold, reach similar conclusions. (Please see http://swpdelivery.water.ca.gov/ and comments submitted regarding the instant EIR by Arve Sjovold.) [2][Fn 2 from letter]: See Appendix E page E-94 at http://swpdelivery.water.ca.gov/SWP%20Delivery%20Reliability.final.2002.pdf.	
51h	PCL/CPA	Controversy over the reliability report, on which this EIR relies, led to review of CALSIM II modeling by an External Review Panel including some of the world's leading experts on water resource systems. Their report, "Strategic Review of CALSIM II and its Use for Water Planning, Management, and Operations in Central California" was released on December 4, 2003. The Panel raised serious concerns regarding the application of the model to predicting reliable deliveries, especially as those deliveries related to particular contractors. Many of the Panel findings agree with concerns we have articulated throughout the Monterey EIR process. Notably, the Panel found that: • "Examination of the report "CALSIM II Simulation of Historical SWP/CVP Operations,' DWR (2003) indicates that the current formulation of CALSIM II: Overestimates water deliveries to SWP and CVP contractors…" (p. 11) • "Most successful applications of optimization [CALSIM's type of computer model] …have calibrated	Please refer to Response to Comment 25.

No.	Commenter	Comment	Response
51h (cont)	PCL/CPA	• their objective functions…so that the model results correspond to what actually happens or would happen under a particular hydrologic and demand scenario…It does not appear that such a calibration of the objective function weights in CALSIM has yet been completed." (p. 4) • "…currently many users are not sure of the accuracy of the results. A sensitivity and uncertainty prediction capability and analysis is needed" (p. 8) • "In our opinion, CALSIM II has not yet been calibrated or validated for making absolute predictions values." (p. 9) • Regardless of how possible it is to match the model closely with observed behavior, statistics on the accuracy of the calibration run should be supplied to users to enable them to gauge the likely errors involved with using the model output. (page 9) • In CALSIM II, "Groundwater resources are assumed infinite, i.e., there is no upper limit to groundwater pumping." (p. 8) • "Realistic upper bounds to pumping from any of the aquifers represented in the model need to be developed and implemented." (p. 27) • "In general, the level of representation of groundwater in CALSIM II is not reasonable from the point of view of the reviewers." (p. 27) • "In many cases, it appears that water use and other hydrologic data inputs to CALSIM II are based on data collection and analyses that took place during the 1960's when DWRSIM and PROSIM were being constructed. It is important to ensure that data used for CALSIM II are up-to-date and consistent with the best current information." (p. 20). • In general, it appears that the developers of CALSIM II do not have a clear idea of how to define the scope of CALSIM II use and many of its applications are evolving in a reactionary manner. Model developers	

No.	Commenter	Comment	Response
51h (cont)	PCL/CPA	should identify clearly the desired uses for CALSIM II and then determine acceptable approaches for satisfying those desires. Developers should seek to improve data accuracy and overcome unrealistic assumptions to improve the confidence in model results. (page 25)	
52	PCL/CPA	Furthermore, as numerous CEQA cases have consistently held, local agencies such as CLWA have an independent responsibility to adequately assess reliability. Castaic therefore, and cannot rest its analysis solely on its old DWRSIM studies and the DWR Reliability Report.	The *PCL* and *SCOPE* cases (*Planning & Conservation League v. Department of Water Resources* [2000] 83 Cal.App.4th 892 and *Santa Clarita Organization for Planning the Environment v. County of Los Angeles* [2003] 106 Cal.App.4th 715) do not require CLWA to formulate an independent model to assess SWP supply reliability. DWR is the state agency that manages and operates the SWP. It is also the state agency responsible for development and periodic updates of the statewide water plan. As such, DWR is in the best situation to have the SWP-specific knowledge and operational experience necessary to estimate SWP supply reliability, as well as knowledge of the broader statewide water user information affecting future SWP reliability. The modeling tools that DWR has developed are based on this extensive experience and knowledge. CLWA and other SWP Contractors have participated in extensive discussions with DWR regarding the development, use and adequacy of the DWRSIM and CALSIM II models. While recognizing that no model is perfect, DWRSIM, the DWRSIM studies conducted for the CALFED Bay-Delta Program EIS/EIR, CALSIM II, and the CALSIM II studies contained the SWP Delivery Reliability Report provide the most comprehensive and accurate assessment of SWP reliability available. Additionally, in their comment letter on the DEIR, DWR stated that the DEIR "adequately discusses the reliability of the SWP, pre- and post-Monterey Amendment conditions, future conditions, and SWP operations." (See Response to Comment 5) The SWP is a very complex water system. Its operations are governed by river flow requirements, Delta regulatory and

No.	Commenter	Comment	Response
52 (cont)	PCL/CPA		water quality requirements, and facility constraints; its operations must be coordinated with the U.S. Bureau of Reclamation's (USBR) operation of the comparably complex Central Valley Project system; and all of these operations are affected by numerous other water users upstream of the Delta. Added to this system complexity is the more typical water supply uncertainty due to hydrologic variability. SWP supplies to an individual SWP Contractor are further affected by the demands of the other Contractors. Given the complexity of this entire system, CLWA relies on DWR to provide the best estimate of SWP supply reliability. Also, as directed by DWR, the SWP Contractors must factor their other available water supplies into their assessments of SWP supply reliability.
53	PCL/CPA	Without adequate review, the transfer would place available water in one of the places in California most likely to promote urban sprawl and destroy environmental habitat The Draft EIR's growth inducement section (Chapter 4) fails to appreciate the significance of this transfer as a linchpin of sprawl development. Following the *PCL* decision and through the Monterey EIR, the state has a responsibility and, as noted above is the only entity with the requisite resources and purview, to determine the environmental impacts, particularly including induced growth impacts, of transfers such as the 41,000 acre-foot transfer. Local agency analysis of these impacts prior to the Tier I Monterey EIR impermissibly and imprudently ignore the state's role in considering alternatives to that transfer which would, for example, meet existing shortfalls in developed Southern California dependent on diminishing Colorado River supplies, while avoiding "dumb growth" in the undeveloped frontier at the Los Angeles-Kern County border.	Please refer to the Master Response and to Comments 37 and 50 and the Responses thereto. CLWA has no jurisdiction over land use planning. Nonetheless, Chapter 4 of the DEIR analyzes the potential indirect (growth related) impacts of the Project. CEQA does not require CLWA to speculate that land use plans might lead to urban sprawl or destroy habitat. CEQA does not require CLWA to analyze growth inducing impacts that are not reasonably foreseeable. City and county land use plans are an appropriate benchmark for what constitutes a reasonably foreseeable impact. Any new project that proposes to rely upon the transferred Table A Amount will have to satisfy CEQA requirements to describe its environmental impacts, provide public notice and information, and mitigate its impacts. The Project, by its nature, does not create the kinds of impacts described in this comment, and it will be the job of appropriate planning agencies to ensure that future land use decisions do not promote urban sprawl or destroy environmental habitat. The DEIR analyzes the indirect environmental impacts of the Project, acknowledging that firming up and augmenting local water supplies will remove one obstacle to growth. CLWA has a responsibility to provide water for future

No.	Commenter	Comment	Response
53 (cont)	PCL/CPA		population and housing needs projected in local general and area plans to the extent feasible and consistent with law. The cities and counties have been charged by the California Legislature to govern issues of urban growth while addressing the environmental concerns resulting from growth. To that end, local agencies with land use authority have adopted general plan documents to appropriately plan for and mitigate the environmental impacts of future development within their respective jurisdictions. Each of the local general plans has a final environmental document that analyzes potential environmental impacts of the growth described in the document, and proposes mitigation measures for those impacts. The *PCL* decision concluded that DWR was the proper lead agency for a project that impacted SWP facilities, contracts and operations statewide. The *PCL* decision did not hold that if a project's environmental impacts relate to statewide issues that a state agency should be the lead agency. The key reason for DWR being designated by the *PCL* court as the appropriate lead agency was that the Monterey Amendments involved changes in the operation of statewide infrastructure, substantive changes in SWP contracts statewide and disposition of state-owned land. If *PCL* stands for the proposition that state agencies must be the lead agency where an environmental issue is a statewide issue, such as urban sprawl, then it would require state agency review of virtually every major local development project and would eviscerate CEQA statutory and regulatory provisions that require local lead agency environmental review. The new Monterey Agreement Program EIR will not analyze in detail growth inducing impacts on the Southern California region, and on the CLWA service area in particular, as suggested by the commenter. A programmatic EIR by its nature will focus on wider programmatic impacts of the Monterey Amendment, which impacts may include growth

No.	Commenter	Comment	Response
53 (cont)	PCL/CPA		inducing impacts in the urban areas of Southern California that receive permanent Table A transfers. Further, with respect to the suggestion that the DEIR should consider alternatives to the 41,000 acre-foot transfer, those are alternatives more appropriately suggested to DWR for consideration as it prepares its new Monterey Amendment Program DEIR, to the extent that the alternatives are feasible or acceptable. Those alternatives are not appropriate in the analysis of impacts of the Project.
54	PCL/CPA	Rather than squarely confronting the scope and mitigation of growth inducement, the Draft EIR improperly defers the issue to subsequent decisions of local agencies on individual projects. A "chicken and egg" problem emerges here. As reflected in PCL's comment letters on specific projects, local agencies are relying upon *Castaic* to inform them of the reliable water available to support specific proposed projects ranging in scope from small developments to Newhall Ranch. The Draft EIR is entirely speculative in its assumption that project-related growth can be mitigated to insignificance. This issue cannot be credibly reviewed in isolation from the statewide Monterey EIR.	Please refer to the Master Response and to Comments 12, 22, 23, and 53 and the Responses thereto. Please note that CLWA has worked closely with DWR (see Comments 2 through 6 and the Responses thereto) to ensure that the approach to analyzing impacts of the Project will be consistent with the approach taken by DWR in preparing its Monterey Amendment DEIR. CLWA's analysis of the indirect impacts of the Project, associated with growth, acknowledges that environmental impacts will occur and relies upon the local land use agencies to perform their analysis and mitigation of future projects consistent with CEQA. CLWA's reliance on local land use agencies is consistent with requirements by the California Legislature that the local land use agencies include a water supply assessment as part of its environmental impact analysis and mitigation for development projects. (See Water Code §§ 10910, 10911.) Contrary to the suggestion in the comment, CLWA does not assume that project-related growth can be mitigated to insignificance. CLWA has no land use regulatory authority and must rely upon local agencies to exercise their authority in a manner consistent with all applicable laws, including CEQA. CEQA does not require CLWA to implement mitigation measures that are outside CLWA's jurisdiction and that fall within the jurisdiction of local land use agencies. Each of the general and area plans adopted by land use agencies within CLWA's service area underwent CEQA review prior to adoption. Those environmental documents are final and not subject to challenge. This DEIR has relied upon those plans and their mitigation measures approved under

No.	Commenter	Comment	Response
54 (cont)	PCL/CPA		CEQA in projecting and addressing indirect growth inducing impacts of the Project.
55	Public Citizen	Public Citizen, a consumer rights organization that has been working to strengthen public oversight over water, urges Castaic Lake Water Agency to refrain from conducting the environmental review of permanent transfers of State Water Project Table Amounts. We believe that is unlawful for CLWA to be the lead agency under CEQA for this project because the Department of Water Resources is currently conducting its statewide review of the "Monterey Plus" Project. Please refer to the Sierra Club's August 15 letter for further reasoning why the DWR must be the lead agency.	Please refer to the Master Response.
56	Public Citizen	We request that this document be withdrawn and that the document not be re-submitted for circulation until the Monterey Agreement EIR is completed and certified.	Please refer to the Master Response.
57	SCOPE	As we stated in our NOP comments, we believe that Dept. of Water Resources must be the lead agency for the following reasons: ▪ The published appellate decision in PCL v. DWR, 2000 found that the Dept. of Water Resources should be the lead agency for this review. ▪ DWR is best suited to ensure that widespread notification of interested parties occur. ▪ DWR is best suited to recognize environmental impacts that might be incurred to a wide spread area of the state as a result of this water transfer and to properly assess such impacts. DWR, in its capacity as operations manager of the SWP, will be acquainted with other state projects that would affect or be affected by this transfer.	Please refer to the Master Response. The published decision in the *PCL* case did not concern this Project and made no finding with respect to the environmental review for this Project. The *PCL* case involved a programmatic EIR affecting the entire SWP system and all of its contractors. This Project involves a project EIR for a transfer between two SWP contractors. DWR and WRMWSD participated in helping CLWA identify parties to whom notice was given. The areas affected by the Project are the receiving and sending areas associated with this 41,000 acre-feet transfer. DWR is not the agency best suited to provide notice to those areas or to analyze potential site-specific impacts in those locales. A local agency has more knowledge of those parties who should receive notice and more information regarding potential localized impacts. As to those areas, CLWA has provided notice as required by CEQA, and CLWA can properly analyze the potential Project impacts in those areas. Notice to other areas under the jurisdiction of DWR is not necessary or required by CEQA. CLWA made a concerted effect to identify and notify potentially interested parties regarding this DEIR,

No.	Commenter	Comment	Response
57 (cont)	SCOPE		including parties who are outside CLWA's and WRMWSD's service areas, but who might have an interest in the DEIR and the Project. With respect to DWR knowledge of State projects that may have an effect on the Project, DWR's knowledge has been shared with CLWA in DWR's capacity as a responsible agency. See Comment 6 and the response thereto. With regard to WRMWSD knowledge of WRMWSD projects and localized impacts, WRMWSD's knowledge has been shared with CLWA in WRMWSD's capacity as a responsible agency.
58	SCOPE	Changes to water quality including increased chlorides, nitrates or other constituents of SWP project water, and how these constituents will affect the new TMDL requirements approved by Regional Water Quality Control Board approved subsequently to the previous EIR, should be discussed and mitigated. Increased pollution from Trihalomenthanes in public water supply due to higher percentage of reliance on SWP project water as main source should be disclosed. Trihalomenthanes now exceed the new MCL standards after filtration by CLWA due to the filtration method currently used.	The Project does not contemplate or cause a change in regulatory water quality compliance levels. The Project does not include or cause an increase in contaminant levels of Castaic's SWP water deliveries. New TMDL requirements approved by the Regional Water Quality Control Board are not part of or caused by the Project. As shown by DEIR Table 3.15-4 and as discussed on pages 3.15-8 through 3.15-9 and 3.15-25, the average water quality for SWP deliveries to CLWA is well below MCL (Maximum Contaminant Level) standards for chlorides, nitrates and other constituents. As shown by DEIR Table 3.15-10 water quality test results for drinking water within CLWA, including both SWP water and groundwater supplies, show typical values well below MCL standards for identified constituents, including chloride, nitrate and trihalomenthanes (THMs). The issue of chloride concentration deals with indirect impacts to local surface water from water discharges after use. As set forth on DEIR pages 3.15-24 and 3.15-25, the primary cause for high chloride concentration is water softeners. As DEIR page 3.15-25 notes, Sanitation Districts of Los Angeles County has adopted an ordinance that prohibits the installation and use of self-regenerating water softeners in the Santa Clarita Valley.

No.	Commenter	Comment	Response
58 (cont)	SCOPE		As DEIR Section 4.2.15 states, because all new development will be regulated by that ordinance, indirect chloride loading impacts to local surface water will be mitigated to a less than significant level. With respect to THMs, which can be produced under certain conditions by water treatment processes using chlorine, CLWA's Rio Vista Water Treatment Plant uses a treatment process that utilizes both chlorine and ozonation, and is in compliance with THM MCL standards. As noted in DEIR Section 6.3.3.1, CLWA is upgrading the Earl Schmidt Filtration Plant to comply with current and proposed water quality regulations. The Earl Schmidt Filtration Plant and the Rio Vista Water Treatment Plant will be in compliance with water quality standards by June 2005.
59	SCOPE	This document relies on transfers to the Semi-Tropic Water Banking project for supply reliability, but does not address potential water quality issues that could preclude groundwater from being pumped back into the aqueduct. This is an issue that would be addressed if DWR were the lead agency. We incorporate by reference all contracts between, DWR, CLWA, and Semitropic, particularly the pumpback agreements and sections of the EIR indicating high arsenic and radon levels in the Semi-tropic groundwater basin. There is no up to date water quality data from the groundwater in the Semi-Tropic area included in this report. If the Semi-tropic Water Storage program is going to be relied upon to increase water supply reliability, then water quality data should be made available for review.	The DEIR does not rely on either the 2002 or the 2003 CLWA Water Banking projects in its water supply reliability analysis. DEIR Sections 3.0 and 3.15 make clear that the DEIR relies on two 1998 studies using the DWRSIM model to assess water supply reliability. Those studies took place prior to the water banking projects. The 2002 and 2003 water banking projects are short term and are separate and independent from the Project. They are not intended to, and do not, provide long-term water supply upon which new development can rely. Those water banking projects are not transfers as suggested in the comment; each constitutes a temporary one-time storage of prior SWP deliveries to CLWA, as described in DEIR Section 6.3.3.1. This comment seeks to improperly apply to the Project the issue of potential water quality impacts of pump-back provisions for the water banking projects despite the finality of the environmental review for those two water banking projects. The 2003 water banking project negative declaration became final without any challenge having been filed within the statute of limitations period. The 2002 water banking project has already been litigated and the Ventura County Superior Court judgment in favor of CLWA is now on appeal.

No.	Commenter	Comment	Response
59 (cont)	SCOPE		The issue of groundwater quality impacts resulting from pump-back provisions was raised in the *Network* case; the trial court concluded that the negative declaration adequately analyzed the issue. As the July 14, 2004 Ventura Superior Court decision in *Network* explained, "Petitioners contend that the initial study was inadequate, particularly in its water quality component. The delivery agreement between DWR, Castaic and the Kern County Water Agency requires that ground water re-introduced into the aqueduct must meet the terms of the Semitropic Turn-in Agreement (AR 13:2573), the net effect of which is that water must meet DWR's then current water quality criteria (AR 12:2248). As such, there is no potential for an outdated water quality standard to be applied." The *Network* case is presently on appeal. The Administrative Record in the *Network* case, which can be found at the CLWA Administrative Office, showed that the Semitropic groundwater does not contain levels in excess of drinking water primary MCLs or in excess of imported (secondary) SWP water quality standards. (See *Network* Administrative Record 1:138, 139, 140; Tables 5-11 & 5-12; 8:1542-43, 1542-43.) That Administrative Record showed that water pumped by Semitropic under its Groundwater Banking Program has met DWR water quality standards. (See *Network* Administrative Record 47:2501.) In addition, the 1994 Semitropic Groundwater Banking Project EIR, which also can be found at the CLWA Administrative Office, included information showing that the groundwater sub-basin used for water banking creates a barrier against and prevents poor groundwater quality migration. (See *Network* Administrative Record 400)
60	SCOPE	In conclusion, we request that this document be withdrawn, that the document not be resubmitted for circulation until the Monterey Agreement EIR is completed and certified, and that all parties whose groundwater may be impacted are properly notified when re-circulation occurs.	Please refer to the Master Response.

No.	Commenter	Comment	Response
61	Sierra Club	In the notice of preparation for this project, the Castaic Lake Water Agency announced its intention to move forward within its own separate environmental review of permanent transfers of State Water Project Table A Amounts. The Sierra Club and others commented at that time that such a procedure would violate state law, several court decisions and the Monterey Agreement Settlement to which CLWA is a signatory. As you are aware, in the Monterey settlement agreement, which Castaic signed, the court-identified lead agency, the Department of Water Resources. DWR is already conducting a statewide environmental review of a new "Monterey Plus" project. We strongly urge Castaic to refrain from moving forward with this separate project review, which is premature and likely to operate at cross-purpose with DWR's statewide review.	Please refer to the Master Response. Please see Responses to Comments 10 and 44.
62	Sierra Club	Moreover, even if Castaic continues to proceed now with its own separate EIR on this transfer, it lacks the institutional authority and statewide accountability to serve as CEQA lead agency under the Planning and Conservation League decision.	Please refer to the Master Response. The reference in *PCL* to institutional authority and statewide accountability refers to facilities and territory of DWR, both of which were issues pertaining to the Monterey Amendment EIR, not to this Project-specific DEIR.
63	Sierra Club	The Sierra Club re-iterates the following legal issues put forward in January 2004 comment letter by the Planning and Conservation League. These issues were either ignored or inadequately addressed in the Environmental Impact Report now under review: The "Monterey Amendments" Problem. Under Planning and Conservation League and two sequel decisions addressing Castaic's transfer of Table A amounts, "tiering" or otherwise relying on that EIR would render the approval decision vulnerable to CEQA challenge. However, any attempts by Castaic to conduct a separate Monterey review in advance of DWR's, or to rely on its own hypothetical non-Monterey analysis, would shift rather than solve this fundamental CEQA problem. In *Planning and Conservation League*, the Third District Court of Appeal found that Central Coast Water Agency's 1995 EIR	Please refer to the Master Response and to Comment 43 and the Response thereto. This DEIR does not undertake to conduct a separate Monterey Amendment review in advance of DWR's new Monterey Amendment EIR. Contrary to the assertion in the comment, the *SCOPE* decision did not address CLWA's characterization of the transfer. The *SCOPE* case addressed the assumption made in the environmental analysis of the development project, conducted by the County of Los Angeles as lead agency, that 100% of CLWA's Table A Amount would be available for delivery in all years, without discussing DWR models, historic SWP deliveries, or valid projections for future SWP delivery reliability. The court rejected this assumption, finding that it

No.	Commenter	Comment	Response
63 (cont)	Sierra Club	"failed to meet the most important purpose of CEQA, to fully inform the decision makers and the public of the environmental impacts of the choices before them." (83 Cal.App.4th at 920.) CCWA improperly served as lead agency in place of DWR and prejudicially failed to analyze the enforcement of the pre-Monterey permanent shortage provision, article 18(b), prior to its elimination from the State Water Project contracts. The appellate court found it unnecessary to adjudicate the other CEQA deficiencies identified by the Monterey plaintiffs after analyzing the defects in the lead agency selection and no project assessment, observing that "DWR, with its expertise on the statewide impacts of water transfers, may choose to address those issues in a completely different and more comprehensive manner." (*Id.*) The court also noted that the deficiencies in the 1995 EIR might be related to the "provincial experience" of CCWA. (*Id.*) In *Friends of the Santa Clara River v. Castaic Lake Water Agency* (2002) 95 Cal.App.4th 1373, the Second District Court of Appeal ordered the decertification of an EIR prepared by Castaic, supporting its Monterey Amendments-based attempt to permanently acquire 41,000 acre-feet of State Water Project entitlements (now "Table A" amounts) from the Kern County Water Agency and its Wheeler Ridge member district. The appellate court found that Castaic's EIR violated CEQA by "tiering" from the invalidated Monterey EIR. This ruling involved precisely the same transfer that Castaic now attempts to address in its separate 41,000 NOP. That piecemeal approach, however, is in apparent defiance of the expectation of the court of the appeal in the Friends case that Castaic would await "action by the DWR complying with the PCL decision." (95 Cal.App.4th at p. 1388.) Another recent Second District appellate decision, *Santa Clarita Organization for Planning and the Environment (SCOPE) v. County of Los Angeles* (2003) 106 Cal.App.4th 715, critically addressed	was not based upon adequate evidence in the administrative record, and thus concluded that the environmental analysis was inadequate. In contrast, this DEIR uses DWR modeling to project reliability of the Table A Amount transferred for this Project. With regard to the cases addressing interim use of the water from the Project, none of those cases are relevant to the present environmental review of the Project. Therefore, they do not constitute evidence of a significant environmental impact resulting from the Project. Please also refer to Responses to Comments 23, 39, 46, and 47.

No.	Commenter	Comment	Response
63 (cont)	Sierra Club	Castaic's characterization of the 41,000 acre-feet transfer. In that case, the County of Los Angeles violated CEQA in its review of the West Creek development project that erroneously assumed that 100 percent of Castaic's purported 41,000 acre-feet would be available in wet years and 50 percent in drought years. Drawing on Planning and Conservation League's assessment of the historic disparity between Table A amounts and deliverable water, the court concluded that the EIR failed to undertake a "serious and detailed analysis' of State Water Project supplies, and observed that "[t]he dream of water entitlements for the incomplete State Water Project is no substitute for the reality of actual water the SWP can deliver." (*Id*. at pp. 723, 717.) The EIR appears to confuse the legitimacy of Castaic's separate review with the distinct issue of the interim operation of the 41,000 acre-feet transfer pending further environmental review. (See Public Resources Code section 21168.9; 41,000 NOP p.1) The trial court did not enjoin interim operation, but left the issue open to further demonstrations that could lead to interim prohibition. Various cases addressing the interim use of this water for new projects prior to the completion of CEQA review are now working their way through the Court system. The 41,000 acre-feet transfer is not on the list of Table A amount transfers recognized as "final" in the Monterey Amendments settlement agreement (Attachment E.). Such transfers cannot proceed without new environmental analysis satisfying CEQA. (Monterey Settlement Agreement, section VII.A.) That settlement agreement, while recognizing that the remedial issue remains before the Second District, also requires DWR's "Monterey Plus" EIR to analyze the 41,000 acre-feet transfer, as well as other transfers facilitated by Monterey Amendments provisions, such as other agriculture-to-urban transfers referenced in Article 53 of those amendments. (Section II.C.4.) If Castaic rushes to finality by continuing its separate	

No.	Commenter	Comment	Response
63 (cont)	Sierra Club	environmental reviews at this stage, without the benefit of DWR's statewide "Monterey Plus" EIR, its perspective would mirror the "provincial experience" criticized in the *Planning and Conservation League* decision. (83 Cal. App. 3d at 918.) Such an attempt would also create a substantial risk of final decisions based on local analysis that may well prove inconsistent with DWR's "Monterey Plus" EIR.	
64	Sierra Club	If Castaic continues with this separate environmental review without awaiting DWR's assessment in the "Monterey Plus" EIR, it would violate CEQA's lead agency requirement based upon the well-established standards set forth in Planning and Conservation League v. Department of Water Resources. The court in that case could hardly have been clearer that DWR is the "state agency charged with the statewide responsibility to build, maintain, and operate" the State Water Project. (Id. At p. 906.; see also Wat. Code, section 12930, et seq.) Finding that DWR was the only entity with the requisite statewide perspective and expertise to serve as lead agency, the court found it "incongruous to assert that any of the regional contractors" could "assume DWR's principal responsibility for managing the SWP." (Id.) Similarly, the court-approved settlement agreement in Planning and Conservation League expressly recognizes DWR's duty as "the State agency responsible for administration and operation of the SWP," as well as its continuing obligation to comply with applicable requirements of CEQA and the Water Code. (Agreement, Section X.B.) The transfer guidelines disclosed to contractors under the settlement agreement also recognize the continuing need to comply with all existing legal requirements, including CEQA, and to honor the lead agency principles identified in the Third District's decision in the Monterey Amendments case. (Agreement, Attachment C.) These principles apply clearly to the proposed permanent transfers of the Table A amounts referenced in the state project contracts, which require DWR's approval and presuppose the	Please refer to the Master Response. The transfer guidelines referenced by the commenter are included in the Monterey Amendment Settlement Agreement and state that the State Water Project contractor, and not DWR, shall be the lead agency for a two party transfer such as this Project. (The two parties are CLWA, the transferee, and WRMWSD, a KCWA member agency.) Because the Project could occur as a pre- or post-Monterey Amendment transfer, the non-Monterey Amendments analysis contained in the DEIR is precisely what the Court called for in the *PCL* case. The analysis addresses what supplies would have been available based on the "agriculture first" cutbacks under pre-Monterey article 18(a). (See DEIR section 3.15.2, including Table 3.15-15.) As DWR notes in its Comment 5, DWR would have provided this same analysis if it had been preparing the DEIR. The quote from the *PCL* case about the necessity for DWR lead agency expertise on statewide impacts of water transfers refers to a statewide program affecting all water transfers, not to an isolated contractor to contractor transfer as in this Project. With respect to the issues of transferring water from agriculture to urban use raised by this comment, please refer to Responses to Comments 44 and 45. The identity of the CLWA manager is not relevant to the adequacy of environmental review in this DEIR.

No.	Commenter	Comment	Response
64 (cont)		application of Monterey. They also concededly require changes in the amount of supplies available to several water agencies, the "location and timing" of project deliveries, and changed utilization of the project's "conveyance and storage facilities." The transfers, which may require the fallowing of farmland in agricultural areas and are associated with proposed annexations linked to some of the more controversial development projects in California, demand the statewide authority and experience that only DWR can provide. Neither the summary references to other project EIRs nor a hypothetical "non-Monterey" analysis of the transfers can substitute for DWR's new assessment of the Monterey changes based on its statewide expertise and authority. For example, although transfers with DWR approval were available under Article 41 of the pre-Monterey State Water Project contracts, it is highly speculative whether agriculture-to-urban transfers such as this proposal would even have taken place without the Monterey Amendments, since those Table A amounts would have been subject to "agriculture first" cutbacks under pre-Monterey article 18(a). Read in context, such maneuvers would amount to little more than "straw man" argument considered and rejected in the Friends appeal. (95 Cal.App.4th at p. 1387.) Lastly, we note that the same General Manager of Central Coast Water Agency, Dan Masnada, under whose guidance, CCWA proceeded in violation of CEQA as the wrong lead agency, is now the general manager of Castaic Lake Water Agency. In that capacity, he is once again directing his agency with full knowledge of the consequences, to proceed as lead agency in violation of the law.	

No.	Commenter	Comment	Response
65	Sierra Club	Communities, local organizations and agencies that would have the most knowledge of impacts surrounding these statewide issues, the accuracy of the environmental disclosure and the viability of proposed mitigation, were not notified. Failure to notice and receive input from interested parties deprives the decision-makers of a full disclosure of all impacts and deprives the affected community or public agency of its right to provide information during the public process. The DWR would be better equipped to ensure that all parties are properly noticed and involved in the project review.	Please refer to the Master Response. This comment provides no specifics and therefore no evidence that proper notice was not given. Please also refer to the responses to Comment 57 and to Attachment B of Volume II of the FEIR.
66	Sierra Club	This EIR purports to analysis statewide issues, including but not limited to, impacts to agricultural lands, sensitive species, the accuracy of the DWR CalSim model, air quality, etc., but since the EIR was not circulated on a statewide basis, the public and agencies from other areas may not have been informed of the release of the document, and thus did not have the opportunity to review its accuracy.	Please refer to the Master Response. CEQA does not require that an EIR that considers statewide issues have a state agency as its lead agency or give notice to all agencies that may have some interest in those issues. Please refer to the responses to Comments 53 and 57 and to Attachment B of Volume II of the FEIR.
67	Sierra Club	<u>Impacts to DWR facilities</u> – Castaic Lake Water Agency cannot presume to be the lead agency for State Water Project facilities.	Please refer to the Master Response. This Project does not impact all or even a majority of SWP facilities. The Project's potential impacts are primarily locale-specific, occurring primarily in Kern County (the sending site) and CLWA's service area (the receiving site), with a minor impact to a small portion of SWP facilities (from KCWA to CLWA)..
68	Sierra Club	Nor does it discuss the ability of the State Water Project facilities to accommodate this huge transfer now that the Metropolitan Water District will be requiring delivery of a greater amount, if not all of its Title A amount. Adequacy of facilities such as the Banks pumping station, effects of the ESA and CalFED Record of Decision, capacity in the San Luis Reservoir in light of recent sharing agreements are not discussed.	The vast majority of MWD deliveries proceed through the East Branch of the California Aqueduct, not the West Branch, through which CLWA receives its deliveries. (See DWR Bulletin 132-02, page 272-275 and 288. The tables on those pages show the large amount of MWD deliveries through the East Branch and show that West Branch deliveries are only at approximately one-half capacity) Amendment 18 to the CLWA SWP contract with DWR provides that DWR will modify the instantaneous rate of flow to CLWA through the West Branch from 99 to 150 cfs. That increase in instantaneous capacity will be more than sufficient to provide for the annualized increase in capacity shown as needed by CLWA for the Project on Exhibit A to Amendment 18.

No.	Commenter	Comment	Response
68 (cont)	Sierra Club		Increased deliveries by MWD through the West Branch combined with increased deliveries to CLWA under the Project will not overtax the delivery system because the Castaic Lake reservoir has sufficient capacity to handle those deliveries. As the DEIR explains at pages 3.15-41 and 3.15-42: "The amount of water stored at Castaic Lake would not be expected to change as a result of the Project. As discussed in section 3.15.1.2, Castaic Lake is the terminal reservoir on the West Branch of the California Aqueduct and is operated to help meet peak deliveries during the summer months for those SWP Contractors that receive deliveries from Castaic Lake and to provide an emergency water supply in case of a major supply system outage. Castaic Lake is also used for year-round recreational purposes. Under normal operations, the amount of storage that is withdrawn from Castaic Lake to make deliveries to Contractors over the summer (the amount withdrawn that exceed the amount delivered to the lake) is typically about 30,000 AF (or about 10 percent of the lake's volume). The amount of this storage withdrawal is small relative to total deliveries from the West Branch, which averaged about 403,000 AF from 1990 through 2000. In other words, most deliveries from the West Branch are conveyed through the California Aqueduct and Castaic Lake in about the same month the water is delivered to Contractors from the lake. In the future, DWR is expected to maintain this same general operation at Castaic Lake regardless of whether deliveries from the West Branch increase, and regardless of whether increased deliveries are due to Table A Amount transfers such as the Project."
69	Sierra Club	<u>Impacts to Agricultural Resources</u> – In a letter dates 5-19-98 from the Planning Department of Kern County to the original Notice of Preparation for this project, a request was made to ensure that the transfer of 130,000 acre feet from the Monterey Agreement was not exceeded. This Agency requested that acknowledgment of previous actions be made in the DEIR and that cumulative impacts of SWP capacity rights be analyzed.	Please find attached as Table A-4 in Attachment A of Volume II of the DEIR, a compilation of total transfers to date under the 130,000 acre-foot amount referenced in Article 53(a) of the Monterey Amendment. As Table A-4 demonstrates, this Project will not cause the amount of total transfers under that provision to exceed the 130,000 acre-foot amount. As noted in the Response to Comment 10, since the 1998 letter referenced

No.	Commenter	Comment	Response
69 (cont)	Sierra Club	We would like to re-state that request for this document and include that letter which you have in your possession by reference into these comments.	by the comment, there have been other transfers outside of the 130,000 acre-foot provision of Article 53(a) pursuant to the Monterey Amendment. As noted in the Response to Comment 49, the present Project was intended by CLWA and KCWA to be included in the 130,000 acre feet of Table A Amount to be made available for transfer from agricultural to urban SWP contractors, but the Project could equally occur under Article 41 of the State Water Project contract without the Monterey Amendment in place. Any agricultural to urban transfers from areas listed in Article 53(a) in excess of 130,000 acre-feet will be processed pursuant to other provisions of the State Water Project contract. Please refer to Comments 68 and 72 and the Responses thereto regarding SWP capacity.
70	Sierra Club	They also requested an analysis of the impacts on the land within the WRMWSD in Kern County including Agricultural Preserve Map 204, 220 and 220No. 4-12-19. Additionally, they requested a table showing "the ultimate potential amount of capacity that could be transferred how many acre feet would be converted to M&I allotment for urban users and as a condition of transfer, if any land in WRMWSD would be permanently fallowed, retired or detached from the District." This information is important because it allows the decision-makers to access the impacts that might be caused to agricultural land or the increase in pumping of groundwater that might be caused by this project.	The May 19, 1998 Kern County letter requests an analysis of Project impacts on the lands within the WRMWSD, including Williamson Act lands. DEIR Section 3.2.2.2.2 explains that because no new construction will occur, the Project will cause no direct losses of Important Farmland or conflicts with existing zoning or Williamson Act contracts. DEIR Section 3.2.2.2.2 also explains that the Project will not cause indirect impacts to agricultural resources within WRMWSD's service area. In years of average or greater than average SWP deliveries, water associated with the 41,000 AF Table A Amount would be in excess of WRMWSD's demands. In years of less than average SWP deliveries, WRMWSD water management actions, including participation in groundwater banking projects, will allow WRMWSD to provide other water resources within the district when SWP deliveries alone are not sufficient to meet demands. Table 3.2-3, which summarizes the change in acreage impacts on the WRMWSD land from 1998 to 2000, provides support for the Section 3.2.2.2.2 analysis. DEIR Section 3.2.1.2 also provides support for that analysis, by stating that there have been no agricultural zoning changes to WRMWSD lands that are part of the Project since 1998. As noted in DEIR Table 3.2-4 and Section 3.2.1.2, lands under

No.	Commenter	Comment	Response
70 (cont)	Sierra Club		Williamson Act contracts in Kern County have increased since 1998. The May 19, 1998 Kern County letter additionally requests analysis of the feasibility of the use of groundwater supplies and of the potential economic losses. DEIR Section 3.2.1.2 provides that analysis, noting that by the year 2001, WRMWSD had developed more than 88,000 acre feet of new annual supply, including groundwater and supplemental water from groundwater banking projects. As evidenced by the discussion in that section, the 1991 financial loss caused by the 1991 drought was reversed and/or offset by the subsequent acquisition of the new groundwater supplies and by the income generated from groundwater banking projects. Also, as noted in DEIR Section 3.2.2.2.2, the reduction in WRMWSD Table A Amount caused by this Project will help reduce financial costs and/or offset financial losses by reducing WRMWSD's share of fixed SWP costs. Alternative sources of water are available to the agricultural operations within WRMWSD's service area at lower overall costs than they would incur by retaining this Table A Amount. Thus agriculture is made more viable by reducing the overall cost of water and by transferring for value Table A Amounts no longer used by WRMWSD. Finally, the May 19, 1998 Kern County letter requests disclosure of the ultimate potential amount of WRMWSD capacity that could be converted to urban use and the amount of fallowing required by WRMWSD for that to happen. DEIR Section 3.2.2.2 demonstrates that the Project will not cause fallowing or conversion or agricultural land to urban uses within WRMWSD. Fallowing will not occur in average or above-average water years, and prior WRMWSD diversification of water sources provides sufficient alternative water supply in the absence of the 41,000 Table A Amount so as to not require fallowing. DEIR Section 3.15.1.2 estimates that under favorable economic conditions, demands within the contract lands are

No.	Commenter	Comment	Response
70 (cont)	Sierra Club		approximately 180,000 to 190,000 AF, and that demands will not increase because the suitable agricultural lands within the district are already in agricultural production. With regard to fallowing, DEIR Section 3.2.1.2 notes that fallowing of an annual average of 27,300 acres occurs regardless of the Project for economic reasons related to crop markets and prices and for agronomic reasons related to pests and disease. Under CEQA, the DEIR does not analyze fallowing or conversion of agricultural land to urban use because these are not foreseeable results of the Project.
71	Sierra Club	The EIR includes a report entitlement "Effects on Agricultural Production…etc." found in Appendix C. We note that this report, included for circulation in the DEIR is labeled as *DRAFT* report. We wonder why the Final Report was not included for circulation and request that CLWA state how they can base their assumptions on a draft report.	The final report has been substituted in place of the draft report. The final report is entirely consistent with the draft report.
72	Sierra Club	A chart found on page 15 of this report is apparently presented in response to the Kern Agency request. It appears to show water need already in excess of WRMWSD Title A amount even using 100% of the water entitlement, a situation that the Court has already found not to be tenable (see foot note 7, PCL v DWR, 2000). This chart is footnoted with the statement that it "Assumes supplies available regardless of source." There is no analysis as to whether this transfer will cause fallowing in future drought years, only the statement that it hasn't in the past. There is also no analysis as to whether overdraft is occurring or will occur in the next drought cycle, only a statement that the chart assumes supplies are available without any explanation of the impacts of over-pumping to make them available. There is no chart that shows how much water was used from what sources before the transfer in question and how much water will be needed and how it will be supplied *after the transfer*.	Please refer to Comment 70 and the Response thereto. The Table 4 chart found at page 15 of the DEIR Appendix C, referred to in the comment, does not show WRMWSD demand for SWP water in excess of WRMWSD's Table A Amount. Table 4 estimates the amount of water applied to various crops from various water sources, only one of which is SWP water. However, Table 4 overstates the amount of water applied to crops during limited SWP water supply years such as 1991. (See DEIR Appendix C, Page 14.) Table 4 reflects only actual SWP delivery amounts, not the WRMWSD Table A Amount. Therefore, Table 4 does not show WRMWSD demand in excess of WRMWSD's Table A Amount. The DEIR provides adequate information to determine that fallowing will not result from the Project. (See DEIR Section 3.2.) As indicated by DEIR Section 3.15.1.2, WRMWSD has several sources of water supply available, including but not limited to groundwater, groundwater banking, and surplus water. DEIR Table 3.15-5 shows the total available supply, and that amount significantly exceeds in recent years the peak demand of 180,000 to 190,000 AFA as set forth in DEIR Section

No.	Commenter	Comment	Response
72 (cont)	Sierra Club		3.15.1.2. As explained in Section 3.15.1.2, demands within the district are not anticipated to materially increase in the future because the suitable agricultural lands within the district's service area already are in agricultural production. As to overdraft, according to personal communication with W.Taube (WRMWSD General Manager), WRMWSD groundwater data and hydrographs indicate that since WRMWSD ceased use of the subject Table A Amount, groundwater levels have increased through time due to return flows from the importation of the current level of supplemental water deliveries, and there is no evidence of overdraft occurring in that portion of the Kern County Groundwater Basin in which WRMWSD is located. As to the use of various water supply sources caused by the Project, DEIR Section 3.2.2.2.2 explains that prior WRMWSD diversification will allow WRMWSD to continue to provide surface water within the district when SWP deliveries alone are not sufficient to meet demands. Also, as DEIR Section 3.15.2.2 explains, at page 3.15-46, economic decisions made by farmers whether to use local groundwater in-lieu of using imported water are not dictated by the Project. As explained in DEIR Section 3.15.1.2, even if transferred water were needed, and groundwater pumping were the sole source of replacement, the potential environmental impact to WRMWSD would be less than significant, given the significant volume of water in storage and the trend of increasing groundwater levels.
73	Sierra Club	The original purpose of the state water project was to provide a supplementary water source so that groundwater would not be pumped in excess of sustainable levels. Now it appears that this water transfer will bring about the very situation one sought to avoid. We believe it is imperative that CLWA notify all interested parties in surrounding areas of their intention to make this transfer, and of the possible increased need for groundwater pumping if this transfer occurs. Because pumping of groundwater sources to replace state water	Please refer to Comments 70 and 72 and to the Responses thereto. The Project will not require increased groundwater pumping in WRMWSD or KCWA because there are sufficient alternative available water sources, as explained in DEIR Section 3.2.2.2.2. Assuming that the amount transferred were needed by WRMWSD and that groundwater were the only source, Section 3.15.1.2 notes that groundwater production of that amount would have a less than significant impact because there is a vast amount of groundwater in storage, which

No.	Commenter	Comment	Response
73 (cont)	Sierra Club	transferred to other areas will have significant impacts on the Public Trust and the vitality of farming operations, we reiterate, the DWR should be the lead agency for this document.	amount has been increasing since the transfer began, as indicated by groundwater levels. The Project will not result in increased groundwater pumping in CLWA's service areas because the Project provides supplemental water to augment and firm up existing CLWA supplies. Please also refer to Comment 36 and the Response thereto. The public trust doctrine does not apply to the State Water Project, to transfers of SWP water, or to groundwater.
74	Sierra Club	The closing paragraphs of this report include a rather chilling understatement; ***"In a series of consecutive 'dry years', the unavailability of a proportional share of the SWP contract amount may contribute to a mismatch between water supply and demand."*** Have farmers been notified of this "mismatch"? How much fallowing will this cause, what will be the economic impacts to farmers, laborers and communities? Isn't this exactly the question that everyone has requested that the EIR address? Where is the answer? Given the substantial move away from annual row crops into permanent orchards of fruits, nuts and vineyards that require multiple years of investment (see Table 2 on pg. 6), dry years with insufficient state water will substantially damage these crops. <u>*One should also note the increase in groundwater pumping indicated by this table.*</u>	The comment takes out of context the sentence contained at page 22 of DEIR Appendix C. The remainder of that paragraph explains: "However, the effect depends on the annual reliable supply and costs of the water from district wells and other supplemental sources. If the supplies from the supplemental sources offset the reduced SWP entitlement, there should be a limited effect on water availability. Overall, the water supplies from the supplemental sources more than offset the reduced SWP Entitlement and, when the carrying cost of holding excess SWP Entitlement is considered, at a lower cost." This language has been slightly reworded in the final NEA Report, without changing the substance. (See FEIR Volume II, Section 4.) As set forth in the Response to Comment 72, WRMWSD has several different water supply options in a period of multiple dry years. Please also refer to the Response to Comment 70. Also, as set forth in the Response to Comment 72, personal communication with W. Taube indicates that groundwater levels are increasing and there is no evidence of overdraft.

No.	Commenter	Comment	Response
75	Sierra Club	Flooding and water quality changes – In a letter dated May 21st 1998 also from the previous EIR review, the Ventura County Flood Control Department notes that the NOP correctly identifies downstream flooding from increased effluent flows as a potential significant impact. There should be a discussion of the potential for this impact in the DEIR for the project before you.	The referenced letter states: "The initial study correctly identifies flooding as an unknown potentially significant impact. Potential development in eastern Ventura County with additional water allotments could increase the need for additional flood control facilities." The potential for growth-related development to increase flooding is addressed in section 4.2.15 of the DEIR. Also note that the letter from the Ventura County Flood Control Department on the current EIR (included in Appendix A) states that "the District has no comments with respect to flood control and NPDES issues."
76	Sierra Club	Changes to water quality including increased chlorides, nitrates or other constituents of SWP project water, and how those constituents will affect the new TMDL requirements approved by Regional Water Quality Control Board approved subsequently to the previous EIR, should be discussed and mitigated. Increased pollution from Trihalomenthanes in public water supply due to higher percentage of reliance on SWP project water as main source should be disclosed. (See attached news article.)	Please refer to the Response to Comment 58.
77	Sierra Club	This document purports to address statewide issues, but fails to discuss the impacts of the Bay-Delta water quality standards on this project. Again, this is but another example of why DWR must be the lead agency.	These standards are included as part of DWRSIM, the model that was used to identify Project impacts. Please refer to section 1.1 of Appendix D, which includes a description of water quality criteria applicable to the SWP Delta pumping. As discussed in section 3.15.2.2, the Project would have an imperceptible or minor impact on the water quality of the Delta, and all changes would be within applicable quality standards and agreements.
78	Sierra Club	This document relies on transfers to the Semi-Topic Water Banking project for supply reliability, but does not address potential water quality issues that could preclude groundwater from being pumped back into the aqueduct. This transfer project is currently being litigated.	Please refer to the Response to Comment 59.
79	Sierra Club	Growth Impacts – In a letter dated May 12th, 1998 from the City of Santa Clarita, the City states that "the DEIR should define current and anticipated water availability for the CLWA service area as compared to the ultimate buildout of the City of Santa Clarita General Plan, and the Santa Clarita Valley Areawide	Information regarding the existing versus new population that could be served by the Project is summarized in DEIR Section 3-0. As noted, this is dependent upon the availability of SWP water, which can vary from year to year. The population that could be served by the Project is compared to relevant growth

No.	Commenter	Comment	Response
79 (cont)	Sierra Club	Plan. This information was requested to clearly identify the need for the project, and should be included for the current project. The City's requests for disclosure in the areas of geology, growth inducement and impacts to Kern County groundwater and development monitoring system analysis should also be addressed for the current project.	projections in Section 5.3. The referenced letter from the City of Santa Clarita does not address impacts to Kern County. These issues were addressed in the DEIR, however, for both the CLWA and WRMWSD service areas. (The development monitoring system (DMS) is a list of proposed and approved projects that is maintained by the County of Los Angeles, and the analysis of cumulative impacts based on DMS projects is specific to the CLWA service area.)
80	Sierra Club	In response to this question, the CLWA relies, but pretends not to rely, in the Urban Water Management Plan that is being litigated. The issue under litigation is over-statement of water supply, particularly the reliance on the availability of polluted water from wells that are now closed because they exceed the MCL for ammonium perchlorate. The Sierra Club requests than an analysis of the impact of growth in a multiyear drought scenario in the Santa Clarita Valley be conducted as part of this EIR. Santa Clarita is now relying on state water as its primary source of supply (since the groundwater is either fully committed or polluted –see attachment). We believe it would be particularly important for decision makers to understand the impacts of the recurrence of the historical SWP worst-case scenario when only 13% of the contractors' Title A amounts were available. (See notes attached from presentation to Santa Clarita City Council, June 29, 2004. Transcript to be provided before Final EIR is released.)	Please refer to Response to Comment 24. The DEIR does not tier off nor rely on the UWMP for any information, including information regarding estimates of water supply, water use, water demand, or water supply reliability. DEIR Section 3.15.1.3 provides a discussion of the studies that were relied upon for its information. As a review of pages 3.15-19, 3.15-20 and 3.15-26, 3.15-27 and 3.15-28, the DEIR's analysis of the perchlorate issue is based on recent studies and reports, not the UWMP. As stated in DEIR Section 5.6, "Although information in the UWMP was considered in the analysis for the Project, an independent analysis and determination of environmental impacts was carried out for the Project." The analysis requested in the comment was performed in the DEIR (refer to section 3-0, "Population and Housing Impacts, Allocation of Project Water to Existing and Future Users;" section 3.10.2.2.3; and section 4.2). Three scenarios were identified, including a multiple dry year period (this supply is the average amount of water available over the four consecutive drought years of 1988 through 1991 based on DWRSIM model results). The single dry year supply is the supply available in the single year with the lowest total SWP deliveries based on DWRSIM model results, which occurred in 1977. In this single dry year, the supply was about 22% of Table A Amounts, and the increase in SWP supply due to the Project was estimated to be 9,200 acre-feet. If instead the supply in a single year were 13% of Table A Amounts, then the increase in supply due to the Project would be reduced to 5,300 acre-feet. Any environmental impacts based on this lower

No.	Commenter	Comment	Response
80 (cont)	Sierra Club		supply amount would be less than those described in the DEIR. Use of the 22% supply amount results in analysis of the worst-case environmental impact assessment scenario.
81	Sierra Club	<u>Sensitive species</u> – The current project is based on an EIR that does not address impacts to endangered species as a result of the entitlement transfer. Draw down of groundwater will result in reduction or elimination of surface water and may occur in both the transferring and receiving agencies (during drought periods when state water is unavailable) as a result of this project. Since species issues were not addressed in the Warm Springs/Maricopa/Belridge EIR, they should be addressed for the proposed project, as its implementation would cause significant impacts. These include impacts to endangered species impacted in both areas including but not limited to the San Joaquin Kit Fox in the WRMWSD and the Unarmored Three-Spine Stickleback in the Castaic Lake Water Agency. The Kit fox could be impacted by draw down of groundwater that impacts surface flows or diversion of surface flows required by lack of state water project supplies. The Stickleback could be affected by increased effluent flows that cause a change in surface water quality (this problem has already been identified as an area of concern by the Regional Water Quality Board) or increased pumping of groundwater required to make up for delivery cutbacks during a drought. Impacts and proposed mitigations should be discussed. We note that a section 4d consultation may be required if endangered species will be affected and request that the US Army Corps of Engineers be sent notification of this project since it appears that they have not been so notified.	The comment that the current project is based on an EIR that does not address impacts to endangered species as a result of the entitlement transfer analysis is not correct. The Supplemental Water Project EIR is a stand-alone document and is not based on any other EIR. Impacts to special status species are addressed in section 3.4, Biological Resources. No mitigation measures are identified, because no significant impacts would occur. Section 4d of the Endangered Species Act is not applicable to this project, because no impacts to threatened species would occur. A copy of the DEIR was sent to the Ventura Office of the U.S. Army Corps of Engineers (refer to Attachment B of Volume II of the FEIR), but no comments were received from that agency.
82	Sierra Club	The EIR includes a list of sensitive species in Appendix B, but does not discuss how these species will be affected when substantial over-draft occurs, either due to over-reliance on this SWP water in the Santa Clarita Valley without sufficient back up sources or over-draft in the farming areas due to transferring away to much of their supplemental SWP water supply.	Please refer to the Responses to Comments 36 and 72 for a discussion about groundwater supply. This Project is not a groundwater project. The Project augments CLWA's groundwater supply and will not result in groundwater draw down in the WRMWSD service area. Please refer to the Response to Comment 58 regarding the quality of water provided by CLWA to its purveyors. The comment presents no evidence of a groundwater drawdown that could significantly

No.	Commenter	Comment	Response
82 (cont)	Sierra Club		impact sensitive species. The DEIR analyzes impacts to groundwater and concludes that impacts to the CLWA service area would be beneficial and that impacts to WRMWSD would be less than significant (refer to section 3.15.2). The comment fails to provide factual evidence to support the presumption that overdraft or significant drawdown will occur in either the CLWA or WRMWSD service areas as a result of the Project. Consequently, these comments cannot constitute sufficient evidence of a significant effect upon the environment under Public Resources Code section 21082.2(c). (See Citizen Action To Serve All Students v. Thornley (1990) 222 Cal.App.3d 748 [speculation and generalizations about traffic, parking, economic effects, and earthquake safety did not constitute substantial evidence].)
83	Sierra Club	Further, it has recently come to our attention that Berrenda Mesa has published a draft EIR to withdraw/divert approximately 70,000 AF from local streams and groundwater sources. Since the transfer of SWP surface water will affect ground water pumping sources, this EIR and its impacts must be included and addressed during the water transfer review process. We therefore believe this document must be included in the review process and incorporate it by reference.	Any withdrawal of water proposed by Berrenda Mesa would be a separate project not connected to this EIR or any other CLWA program, nor would it affect the same environmental resources as the Project evaluated in the present EIR. The service areas of Berrenda Mesa and WRMWSD are approximately 50 miles apart, and the service areas of Berrenda Mesa and CLWA are approximately 150 miles apart.
84	Sierra Club	<u>Air Quality</u> – The effect of the project on increasing particulate matter from increased or overdraft use of groundwater in a PM10 non-attainment zone for this air pollution problem should also be addressed. THE EIR only addressed project specific impacts such as pumping facilities and grading for new pipes. It did not address fugitive dust created by dried up landscapes. CLWA is well aware of the problems created by dust due to draw down of Owens Lake and its impact on surrounding communities because one of its Directors helped negotiate the settlement on behalf of LADWP. This is an example of an impact that must be anticipated in both the transferring farmlands and the receiving Santa Clarita area. Santa Clarita is already in a non-attainment zone for PM10s as is the Central Valley. Clean Air Act compliance will be	The potential for fugitive dust emissions to occur due to changes in agricultural practices is considered in section 3.3.2.2.2. Since no changes in agricultural practices would occur, fugitive dust emissions would not increase. A reduction in water supply causing air quality concerns would not occur. Direct air quality impacts in the CLWA service area are addressed in section 3.3.3.3.4. Indirect impacts resulting from induced growth are addressed in section 4.2.3, and it is concluded that impacts may not be mitigable to less than significant. As addressed in the Responses to Comments 70 and 72 and in portions of the DEIR cited therein, the Project will not directly or indirectly cause drawdown or overdraft that might increase fugitive dust.

No.	Commenter	Comment	Response
84 (cont)	Sierra Club	necessary. A cut-back in water supply caused by air quality concerns as already occurred for the LA Dept. of Water and Power in the Owens Valley, would be much more appropriately dealt with in the planning process than after new building is already approved based on that water.	
85	Sierra Club	State Water Reliability – One of the most apparent reasons that the review must await completion of the Monterey "Plus" environmental review is that a new hydrological model "CalSim II" is being proposed for use in evaluating the reliability of water deliveries of the sate project supply. This information is obviously critical to all the above stated issues. There has been substantial criticism of the model (peer review attached). Among other circumstances, the model does not address climate change or levee breaks such as the substantial recent failure in the Jones tract (news article attached). The DWR must complete its environmental review of this issue and resolve discrepancies before reliability factors on which the Castaic EIR is based, can be assumed to be accepted. Again, tiering is based on a DWR document that has not been circulated for review, has not been through the public comment process and has not been certified.	Please refer to the Response to Comment 25 for a discussion of the use of models in the DEIR. Refer to the Master Response for further discussion regarding the comments that the Supplemental Water Project EIR must await completion of the Monterey Plus EIR. Also, please note that this EIR does not tier from the Monterey Plus or any other EIR. It is a stand-alone, project EIR.
86	Sierra Club	We believe that DWR must be the lead agency for the following reasons: ▪ The published appellate decision in PCL v. DWR, 2000 stated: *"We agree with the trial court that DWR, not CCWA, has the statutory duty of assessing environmental consequences of projects involving the SWP* [State Water Project]." (Pg. 1 of Decision). We incorporate this decision by reference into the administrative record. ▪ DWR is best suited to ensure that widespread notification of interested parties occur. ▪ DWR is best suited to recognize environmental impacts that might be incurred to a wide spread area of the state as a result of this water transfer and to properly asses such impacts. ▪ DWR, in its capacity as operations manager of the SWP, will be acquainted with other state projects that would	Please refer to the Master Response and to Comments 2, 3, 4, 5, 6, 53 and 57 and the Responses thereto. The *PCL* case cited in this comment involves a program EIR analyzing the impacts of a major amendment to the SWP contracts statewide, alterations to the operation of the State Water Project, and the state's transfer of the Kern Fan Element property. For all of those reasons, the court in *PCL* held that DWR must be the lead agency for the Monterey Amendments Program EIR. This Project is a transfer of Table A Amount from WRMWSD, through KCWA, to CLWA. The Project does not encompass all or even a major part of the various provisions of the Monterey Amendment, does not impact a substantial part of the SWP facilities, and does not interfere with or preempt the Monterey Amendment DEIR process. CLWA has consulted DWR, as a responsible agency, in the preparation of the Project DEIR.

No.	Commenter	Comment	Response
86 (cont)	Sierra Club	affect or be affected by this transfer. ▪ CLWA failed to address many issues of statewide concern in this document.	
87	Sierra Club	We therefore request that this document be withdrawn, that the document not be re-submitted for circulation until the Monterey Agreement EIR is completed and certified, and that all parties whose groundwater may be impacted are properly notified when re-circulation occurs.	Please refer to the Master Response.
88	TCW	It is our understanding that this environmental document is being re-circulated by Court Order because the program EIR on which it was based was set aside in the decision PCL v. DWR, 2000. In that decision the Court found that an individual contractor (Central Coast Water Agency) could not be the lead agency for a state wide project that had impacts to a wide geographical and social group of people. The decision found that the Department of Water Resources should be the correct lead agency. We would like to express our dismay that your agency is now proceeding once again in a manner contrary to law by circulating this document as the lead agency and before the Monterey Agreement EIR has been completed. We note that the same General Manager of Central Coast Water Agency, Dan Masnada, that was found to be in violation of CEQA for proceeding as the wrong lead agency, is now the general manager of Castaic Lake Water Agency. In that capacity, he is once again directing his agency to proceed as lead agency in violation of the law. We believe that the Department of Water Resources must be the lead agency for the discussion of the statewide impacts of water transfers for the following reasons: 1. The published appellate decision in PCL v. DWR, 2000 stated "We agree with the trial court that DWR, not CCWA, has the statutory duty of assessing environmental consequences of projects involving the SWP [State Water Project]." (Pg. 1 of decision). We incorporate this decision by reference into the administrative record. 2. DWR is best suited to ensure that widespread	Please refer to the Master Response and to Comments 57 and 86 and the Responses thereto. The comment incorrectly states that this DEIR is a re-circulation of the prior EIR for this Project. The trial court in *Friends I* set aside the certification of that prior EIR and ordered that CLWA certify a new EIR that complies with CEQA and is consistent with the view expressed by the Court of Appeal in *Friends I*. This DEIR is the environmental document prepared in response to the trial court's order. The identity of the lead agency's manager is irrelevant to the adequacy of the DEIR.

No.	Commenter	Comment	Response
88 (cont)	TCW	notification of interested parties occur. 3. DWR is best suited to recognize environmental impacts that might be incurred to a wide spread area of the state as a result of this water transfer and to properly asses such impacts. 4. DWR, in its capacity as operations manager of the SWP, will be acquainted with other state projects that would affect or be affected by this transfer.	
89	TCW	Many anomalies in the CEQA process have already occurred because the general Manager of Castaic Lake Water Agency has chosen to proceed contrary to law and to the published appellate court decision in a case to which he was a party. This includes the fact that they were not notified of the circulation of this draft EIR, nor were others in water districts including Berenda Mesa and in other areas statewide.	Please refer to the Master Response and to Attachment B of Volume II of the FEIR and to Comment 57 and the Response thereto. The Project's potential environmental impacts primarily occur in Kern County and CLWA's service area. The DEIR also analyzes potential impacts to SWP facilities. The Project effects will occur in limited areas, not statewide. CEQA does not require notice to unaffected areas..
90	TCW	Further, it has recently come to our attention that Berenda Mesa has published a draft EIR to withdraw/divert approximately 70,000 AF from local streams and groundwater sources. Since the transfer of SWP surface water will affect groundwater pumping sources, this EIR and its impacts must be included and addressed during the water transfer review process. We therefore believe this document must be included in the review process and incorporate it by reference.	Please refer to the Response to Comment 83.
91	TCW	The original purpose of the state water project was to provide a supplementary water source so that groundwater would not be pumped in excess of sustainable levels. Now it appears that this water transfer will bring about the very situation one sought to avoid. We believe it is imperative that CLWA notify all interested parties in Berenda Mesa and other areas proposing increased groundwater pumping, of their intention to make this transfer, because pumping of groundwater sources to replace state water transferred to other areas will have significant impacts on the Public Trust and the viability of farming operations.	Please refer to the Response to Comment 73.

No.	Commenter	Comment	Response
92	TCW	Such impacts to groundwater that affect both public trust surface flows and water for farming, should be addressed in the program EIR. It is therefore improper for CLWA to proceed before the completion of the Monterey Agreement EIR.	Impacts to groundwater, surface water, and agricultural resources are addressed in the DEIR (sections 3.2 and 3.15). Please refer to the Master Response and to Comments 2, 72 and 73 and the Responses thereto.
93	TCW	In conclusion we request that this document be withdrawn, that the document not be re-submitted for circulation until the Monterey agreement EIR is completed and certified and that all parties whose groundwater may be impacted are properly notified when re-circulation occurs.	Please refer to the Master Response and to Comments 73, 91 and 92 and the Responses thereto.
94	UWCD	United Water Conservation District has reviewed the Draft EIR for the proposed transfer of 41,000 acre-feet of State Water Project Table A Amount water from the Kern County Water Agency's member unit Wheeler Ridge-Maricopa Water Storage District to Castaic Lake Water Agency. This proposed transfer of SWP water is beneficial to the Santa Clara River Watershed and is fully endorsed by United Water.	This comment is noted; no text revisions are required.
95	UWCD	The permanent transfer of 41,000 acre-feet of SWP water to the Castaic Lake Water Agency provides a valuable additional source of water for the Santa Clarita Valley. This additional water improves the potential for conjunctive-use of water within the valley. This is especially important given the urbanization of this area. Increased surface water supplies should provide water managers throughout the basin more flexibility with respect to the magnitude of additional groundwater pumping needed to meet the escalating M&I demand for water within the basin.	This comment is noted; no text revisions are required.
96	UWCD	Although discussed in various sections within the Draft EIR it should be reemphasized here that 41,000 acre-feet of SWP Table A Amount water doesn't guarantee this amount can be delivered every year. Hydrologic conditions and storage carryover in any particular year primarily dictate the annual allocation of water to the S WP Contractors. Historic deliveries to M&I Contractors should not be used to project future deliveries. The adoption of the Monterey Amendment (following the principles of the Monterey Agreement) will require that M&I Contractors and Agricultural Contractors more equitably share the pain of future water shortages.	This comment is noted; no text revisions are required.

No.	Commenter	Comment	Response
96 (cont)	UWCD	During the previous drought, allocations, as a percentage of table A Amount (Entitlement), to Agriculture contractors were significantly less than allocations to the M&I Contractors.	
97	UWCD	As an ongoing general comment to all water purveyors within the Santa Clarita Valley, United Water has a very real interest in the continued health of the Santa Clarita Groundwater Basin and the flow of the Santa Clara River. United Water represents the collective interests of downstream residents that depend on the flow of the Santa Clara River for recharge to groundwater, surface water diversions and environmental mandates. United Water's goal is that the quantity and water quality associated with the flow of the Santa Clara River into Ventura County not be diminished. The development and implementation of the inter-Agency regional monitoring program of groundwater levels, groundwater quality, surface water flows, and surface water quality should provide ongoing data with respect to the relative health of the Santa Clarita and downstream basins as well as surface water. In the event that surface water flow into Ventura County is diminished in either quantity or quality, and can be reasonably linked to over pumping of the aquifer systems and/or surface water discharges to the river within Santa Clarita Valley, United Water would seek to remedy the problem.	This comment is noted; no text revisions are required.
98	Sjovold	Please accept these comments with the attachments in opposition to the proposed transfer. Besides being an arrogation of power by CLWA unto itself, it flies in the face of the present process at the State level to properly assess the environmental impacts of the Monterey Amendments as mandated by the Court of Appeals. What is particularly troubling is the adoption of material developed by DWR on SWP reliability which is demonstrably in-correct. As a member of the plaintiff committee presently engaged with DWR to fashion a new Monterey EIR, I am quite aware of the issues involved with the CALSIM II model, which is the model used to generate the incorrect information on SWP reliability. The attached analysis shows why the reliability information is incorrect and argues that until the CALSIM II model can	Please refer to the Master Response and to Comments 2 through 6 and 25 and the Responses thereto. The Project does not encompass the Monterey Amendment and does not interfere with or preempt the Monterey Amendment DEIR process. CLWA has consulted DWR, as a responsible agency, in the preparation of the Project DEIR. The analysis attached to the comment refers to the CALSIM II model, with the principal criticism that it overstates deliveries if applied to the last several years. The DEIR used CALSIM II results only in estimating SWP supplies for the current environmental setting. All other SWP supply analyses in the DEIR (i.e., for both the 1998 environmental setting and the environmental impact analyses) used DWRSIM model studies.

No.	Commenter	Comment	Response
98 (cont)	Sjovold	correct its fundamental deficiencies it cannot be relied upon. Without this model's results the CLWA EIR is without any foundation for the claims made concerning the reliability of supplies that CLWA attaches to the SWP. In fact, one can make the argument on the same basis that present CLWA SWP supplies are already overtaxed.	The analysis attached to the comment fails to identify any defect in these DWRSIM model studies used in this DEIR. As set forth in the Responses to Comments 4 and 25, the DWRSIM model studies provided the best estimates of SWP supply reliability that were available when the DEIR supply analyses were conducted, and are consistent with the 1998 environmental setting used in this EIR. Also, as set forth in the Response to Comment 4, the DWRSIM model SWP delivery reliability results were slightly higher than delivery reliability results from the CALSIM II studies that subsequently became available in the DWR SWP Delivery Reliability Report. Therefore, from an environmental impact assessment standpoint, the DEIR analyzed the worst-case scenario, i.e., the scenario that would result in greater direct and indirect impacts in both the CLWA and WRMWSD service areas.
99	Swans	It has come to our attention the Castaic Lake Water Agency is possible planning to affect a position on the above captioned matter which, in our opinion, will gravely impact the Monterey Agreement EIR process. We also wish to comment that we see a direct conflict of interest and possible injustice to the public and interference with the CEQA process by your agency's spearheading any effort to circumvent, delay, interfere, or otherwise impede the more appropriate participation of the Department of Water Resources, the agency we believe entitled to administrate on behalf of the general public of the State of California in this matter. We, the below listed voters and community members raise our voices in writing in complete objection to any and all interference by the Castaic Lake Water Agency and formally request the immediate withdrawal of any and all past, present or future water transfer documents until the EIR is complete. Furthermore, we wish to be added to the list of mailings for any matters regarding this subject.	Please refer to the Master Response and to Comments 2 through 6 and the Responses thereto. Beyond those responses, CLWA is unable to respond to the comment because the comment fails to note in what manner the commenter believes that the DEIR will "gravely impact" the Monterey Amendment DEIR preparation process and fails to explain in what manner the DEIR or CLWA actions "circumvent, delay, interfere or otherwise impede" DWR participation. The commenter has been added to the mailing list for this EIR.

No.	Commenter	Comment	Response
100	Churchill	Water transfers are a statewide issue that induce growth and reduce water for farming. Therefore I believe that your agency is the wrong lead agency for this project; I believe the correct lead agency is the Department of Water Resources, which is both indicated and qualified under state law to address statewide impacts. DWR will also notify all interested parties to the extent of their knowledge. If such a major transfer is allowed to proceed under the lead agency status of a small regional water agency, it will set a precedent that will affect many major water decisions throughout the state of California. I believe it is imperative that such a major change in state policy receive full environmental review and comments from all affected parties. I therefore request that this project be re-noticed by the Dept. of Water Resources acting as lead agency as a project of statewide concern so that all impacts may be disclosed and properly addressed.	Please refer the Master Response and to Comments 53, 54, 70 and 72 and the Responses thereto. The *PCL* decision concluded that DWR was the proper lead agency for a project that impacted SWP facilities and operations statewide, amendment of the SWP contracts statewide, and disposition of state-owned land. The commenter fails to explain how the Project will "set a precedent that will affect many major water decisions throughout the state of California." As explained in more detail in the Responses to Comments 70 and 72 and in the DEIR sections cited therein, the Project will not reduce water available for farming. As noted in the Responses to Comments 10 and 69, this Project is only one of the many recent permanent transfers of Table A Amounts. This Project sets no precedent. The commenter also suggests that the Project represents a major change in state policy. In so doing, the commenter appears to confuse the Monterey Amendment, which does represent a major change in state policy, with the Project, which is a simple transfer of Table A Amount that could occur with or without the Monterey Amendment.
101	Volker	On behalf of California Water Impact Network and Friends of the Santa Clara River, we wish to incorporate by reference the comments submitted on the above DEIR by the Sierra Club. We wish to emphasize, in particular, that Castaic Lake Water Agency is not the correct "lead agency" for this project under the California Environmental Quality Act. As the Third District Court of Appeal made clear in *Planning and Conservation League v. Department of Water Resources*, 83 Cal.App.4th 892, 920 (2000), "DWR, with its expertise on the statewide impacts of water transfers, " is the proper lead agency under CEQA for decisions regarding transfers of State Water Project water between SWP water contractors. We also wish to incorporate by reference our Opening Trial Memorandum (filed August 21, 2003) and Reply Trial Brief (filed May 3, 204) in the matter *California Water Network and Friends of the Santa Clara River v. Castaic Lake Water Agency*, Ventura Superior Court No. 215327. These memoranda point out the importance of recognizing DWR's lead agency status	Please refer to the Master Response. The *PCL* case cited in this comment involves a program EIR analyzing the impacts of a major amendment to the SWP contracts statewide, alterations to the operation of the State Water Project, and the state's transfer of the Kern Fan Element property. For all of those reasons, the court in *PCL* held that DWR must be the lead agency for the Monterey Amendments Program EIR. This Project is a transfer of Table A Amount from one State Water Project contractor to another. DWR and the petitioners in the *PCL* case all acknowledged in the Monterey Amendment Settlement Agreement, Attachment D, Paragraph 4, that a single contractor-to-contractor transfer is not the same as a program that facilitates transfers statewide. The language regarding transfers quoted from the *PCL* case is taken out of context and is inapplicable to a transfer between two contractors as contemplated by this Project. With respect to the unspecified arguments contained in the trial

No.	Commenter	Comment	Response
101 (cont)	Volker	regarding transfers of State Water Project water.	briefs in the case of *California Water Network and Friends of the Santa Clara River v. Castaic Lake Water Agency* [*Network*] Ventura Superior Court No. 215327, the ruling of the Superior Court in that case held: "Petitioners argue that the Department of Water Resources should be the lead agency and cite the court to *Planning and Conservation League v. Dept. of Water Resources*, 83 Cal.App.4th 892. The fact present here are sufficiently different from those present in *PCL* to make the finding in that case that the DWR was the lead agency inapplicable here. *PCL* involved the Monterey Agreement and the resolution of conflict between urban and agricultural allocations of water during times of shortage. The agreement was statewide in its scope and involved 29 agencies. The present circumstance is local in its character and involves the DWR in a much more passive and secondary role. The present project does not involve either a substantial restructuring of the distribution of water, [n]or does it involve water throughout the state. It does involve a diversion of Castaic's water to a water bank, and the subsequent withdrawal of that water. Castaic is the agency most deeply involved in the planning, and execution of this project. It is the appropriate lead agency as described in *PCL*, Public Resources Code section 21067, and 14 CCR 15051(a). DWR is involved, and is a responsible agency, but it is not the lead agency for the project." (Ruling, page 2, line 28 through page 3, line 18.).
102	PM (Plambeck)	I'd just like to express my concern that this EIR is proceeding without completion of the Monterey Agreement. I think the court was fairly concise about the need for the programmatic EIR in both legal decision….	Please refer to the Master Response.
103	PM (Plambeck)	…very concerned about the lead agency, and Castaic Lake Water Agency is not the right lead agency.	Please refer to the Master Response and to Comments 53 and 54 and the Responses thereto.
104	PM (Plambeck)	It was my understanding prior to this that the two EIRs were moving forward in tandem and they would be completed simultaneously.	Please refer to the Master Response.

No.	Commenter	Comment	Response
105	PM (Plambeck)	And I just think that – that the folks up north that challenged the EIR will probably continue to challenge the EIR and that they're going to be very concerned that this is proceeding in a manner that's not consistent with an appellate court decision that they won, and that means that even though you know that's there and you're going ahead and doing this anyway, and it sort of seems like a waste of taxpayer's money since there's already a published appellate court decision on it. And so I would just ask you to keep that in mind and that it might be the better part of valor to move the two EIRs forward in tandem as I understood had been originally planned.	Please refer to the Master Response. Please also refer to the responses to Comments 31, 46 through 48.
106	PM (Bertoni)	First, I'd like to thank the board for providing us this opportunity to comment on the project, on the EIR. You have extended the public comment period beyond the normal 45 days to 60 days. You have also held the public hearing during your comment period, which is not required under CEQA, so you've gone above what's the minimum under CEQA and the City appreciates that and also appreciates being provided with all the documentation very quickly and promptly throughout the whole process. So first off, we'd like to thank you for that.	This comment is noted; no text revisions are required.
107	PM (Bertoni)	Second off, I noticed that by sharing on EIR for water transfer, it's not really the water transfer itself. In regards to the water transfer, I would just say that as we reviewed the EIR it appears that this EIR was prepared for water transfer that would allow to you a few things. One of them would be to provide more reliability in the existing water supply. The other would be to allow for growth that's already been anticipated under existing general plans for both of the City of Santa Clarita and the County of Los Angeles. So to that extent, the City is supportive of that. The City has always been supportive of additional water reliability and also to make sure that as well plan for our future growth, we will have water supplied for that. This city has a couple very high-profile projects that it is very important to the City and the point being the City to have adequate water supply for that. As you know, we're very – a housing rich city. We are trying to	This comment is noted; no text revisions are required.

No.	Commenter	Comment	Response
107 (cont)	PM (Bertoni)	balance that out to be as equally jobs rich and so things such as our employments such as the Center Point Business Park to the south of you or the Gate (inaudible) project in Newhall are very important for the City, very important for the City's goals. So to the extent that this would provide water for that, that's an important City goal. Also, things such as the redevelopment of downtown Newhall and that revitalization would require some additional water. So the supply part of it, the City is supportive of that additional reliability of water supply.	
108	PM (Bertoni)	We reviewed the EIR at the City and we reviewed it under the – to see if it adequately addressed the potential environmental impact to the City of Santa Clarita, and our review indicated that it has. So at this time we have no comment on the EIR and would happy to answer any questions. Thank you.	This comment is noted; no text revisions are required.
109	PM (Wisehart)	The United Water Conservation District has reviewed the draft EIR for the purpose – for the proposed transfer of 41,000 acre-feet of state project water that will come from the Kern County Water Agency's member unit Wheeler Ridge-0Maricopy Water Storage District to the Castaic Lake Water Agency. This proposed transfer of State Water Project water is beneficial to the Santa Clara River Watershed and is fully endorsed by United Water.	This comment is noted; no text revisions are required.
110	PM (Wisehart)	The permanent transfer of 41,000 acre-feet of State Water Project water to the Castaic Lake Water Agency provides a valuable additional source of water for the Santa Clarita Valley. This additional water improves the potential for conjunctive use of water within the valley. This is especially important given the urbanization of this area. Increased surface water supplies should provide water managers throughout the basin more flexibility with respect to the magnitude of additional groundwater pumping needed to meet the escalating M&I demand for water within the basin. As an ongoing general comment to all water purveyors within the Santa Clarita Valley, United Water has a very real interest in the continued health of the Santa Clarita groundwater basin and the flow of the Santa Clara River. United Water represents the collective interests of downstream residents that depend on	This comment is noted; no text revisions are required.

No.	Commenter	Comment	Response
110 (cont)	PM (Wisehart)	the flow of the Santa Clara River for recharge to groundwater, surface water diversions, and environmental mandates.	
111	PM (Wisehart)	United Water's goal is that the quantity and quality of water associated with the flow of the Santa Clara River into Ventura County not be diminished. The development and implementation of the inter-agency regional monitoring program of groundwater levels, groundwater quality, surface water flows, and surface water quality – and you know I am talking about the MOU agreement that we all signed with your upstream purveyors – should provide ongoing data with respect to the relative health of the Santa Clarita and downstream basins as well as surface water. In the event that surface water flow into Ventura County is diminished in either quantity or quality and can be reasonably linked to over pumping of the aquifer system and/or surface water discharges to the river within the Santa Clarita Valley, United Water would seek to remedy the problem.	This comment is noted; no text revisions are required.
112	PM (Wisehart)	We appreciate the efforts of the Castaic Lake Water Agency to appropriately plan and augment the water supplies of our watershed as represented by this water transfer project.	This comment is noted; no text revisions are required.
113	PM (Dunn)	When talking to DWR and asking how that happened, because this agency used to have originally a 23,000 acre-feet per year allocation from the state, that the state DWR would transfer and transport to Castaic Lake for Castaic Lake Water Agency, but DWR also had allocations from many farmers and other water users in the San Joaquin Valley. DWR said that those allocations the CLWA had been subsequently purchasing were designed to take turn-outs in the San Joaquin Valley, and those acre-feet were to get off in the San Joaquin Valley. In other words, they were telling me that the Tehachapi pumping station and the aqueduct, that is I guess mostly owned for use by the Metropolitan Water District, was not designed to transport those farmers' allocations here. So I have asked when I was on the agency and I have asked as a public comment when I'm not on the agency what contracts	Please refer to Response to Comment 68. The vast majority of MWD deliveries proceed through the East Branch of the California Aqueduct, not the West Branch, through which Castaic receives its deliveries. Amendment 18 to the CLWA SWP contract with DWR provides that DWR will modify the instantaneous rate of flow to CLWA through the West Branch from 99 to 150 cfs. That increase in instantaneous capacity will be more than sufficient to provide for the annualized increase in capacity shown as needed by CLWA for the transfer on Exhibit A to Amendment 18.

No.	Commenter	Comment	Response
113 (cont)	PM (Dunn)	do you have with Metropolitan Water District or DWR that says you can transport that water that you are purchasing, those additional purchases here? Doesn't matter is you've banked them up there. Some day you will want to transport them here, and I am told there are no such contracts. We know now that since the Arizona and those people re cutting off MWD's allocations by way of Colorado River, MWD not has to rely more heavily on the DWR an their allocation in this aqueduct and the capacity in the aqueduct. Many unaware, even in our community, that Castaic Lake Water Agency only has 5,000 acre-foot of storage in the Castaic Lake, Many think we've got a real good reservoir here, and we'll really high and dry. And so with the demand that MWD is going to have on the aqueduct now more so demand 'cause you can't get it from the Colorado River, and with the drought situations, and this agency has no contracts that they can transfer those additional allocations here, and I heard nothing in the words tonight just like it was going to be transferred. Nothing was in the Urban Water Management Plan It kind of scares me that we're going to sit here in the drought situation and MWD is going to need their full capacity of Castaic Lake and their full capacity of the state aqueduct, and all this water you purchased you can't bring here. I would like to see that addressed in the EIRs. I would like to see that addressed in the urban water management plans that you can bring this water here.	
114	PM (Mankin)	There is no issue more important in the future of this community than the availability of water. Having available water impacts almost every segment of this community business and consumer marketplace. It's about, again, as all of you know, it's about having local agency being aggressive in the way they find and bring new water into the valley, and most importantly, it's about the economic future of the Santa Clarita Valley. My job as president of the Chamber achieved spokesman of the business community is twofold. First, I work with companies	This comment is noted; no text revisions are required.

No.	Commenter	Comment	Response
114 (cont)	PM (Mankin)	from outside of this market and try to encourage them to locate their company or business here. I am heavily involved in business recruitment. Second, and probably more important, I am actively involved with working with local companies to assure that they have the right kind of political, economic, and physical infrastructure in place to make it possible for them to grow their respective businesses. Regional economic analysts have predicted – and I heard this at a meeting this spring – they predicted that we will generate some 4,700 new jobs here in the valley this year alone. I suspect we're ahead of that pace already. In looking at specific projects, one project, Center Point Business Park which is now under construction will generate an estimate – estimated 8,000 new jobs over the next few years. Many other such project area either now on the books nor have actually started development. There is no issue more important to as many of these companies than knowing that one, two or ten ears from now they can turn on a water facet and actually have water flow out of it. The issue you are discussing this evening will provide these companies with some sense of security that water, in fact, can and will e available to them during times of drought. I highly encourage you to continue to make the necessary decisions that can and will make these new water resources available to both our existing business community and to those businesses that will soon call us home in the future.	
115	PM (Donlon)	BIA is pleased to see that CLWA has produced a new EIR for the litigation pending on the transaction which can be resolved. The CLWA transfer of 41,000 acre-feet of water from Kern County in 1990 represented wise water planning at the time for the Santa Clarita Valley. Such planning and water management programs on the part of CLWA ensures that its current users as well as future users will be assured safe and reliable drinking water. BIA would like to commend CLWA and its agency and staff for taking these preemptive actions.	This comment is noted; no text revisions are required.
116	PM (Donlon)	We urge you to support and certify this EIR.	This comment is noted; no text revisions are required.

No.	Commenter	Comment	Response
117	EHL	Endangered Habitats League is concerned that your agency is the wrong lead agency for this project. Water transfers are a statewide issue that induce growth and reduce water for farming. They should be addressed by an agency that is qualified under state law to address statewide impacts and will notify all interested parties. In this case, this is the Department of Water Resources.	Please refer to the Master Response and to Comments 2 through 6 and the Responses thereto. The Project has localized (in KCWA's service area, the sending site, and in CLWA's service area, the receiving site) and not statewide impacts. The choice of lead agency is determined by many factors (please refer to the Master Response and to the Responses to Comments 37, 39 and 53), not by nature of the environmental issues raised.
118	EHL	The impacts of this transfer are considerable and affect a wide variety of interest, yet sufficient notification has not occurred, for example to our group.	Please refer to Comment 57 and the Response thereto. CLWA made a good faith attempt to notify all interested parties of the EIR's release, sending approximately 250 copies of the DEIR to agencies (including water agencies), organizations, and individuals throughout the state. The distribution list is included in Attachment B of Volume II of the FEIR. CLWA also provided notices regarding the availability of the DEIR to the County Clerk's office of the affected counties. Additionally, the release of the DEIR was noticed in *The Signal* newspaper, and CLWA held a public meeting to present an overview of the EIR and to receive comments on July 28. The meeting notice was posted on CLWA's website, and the meeting was held at 7 P.M. to facilitate the attendance of the working members of the public. All Kern County member agencies were notified. Please see Attachment B of Volume II of the FEIR, the notice/distribution list.
119	EHL	If such a major transfer is allowed to proceed under the lead agency status of a small regional water agency, it will set a precedent that will affect many major water decisions throughout the state of California. It is imperative that this major change in state policy receive full environmental review and comments from all affected parties. We therefore request that this project be re-noticed by the Dept. of Water Resources acting as lead agency as a project of statewide concern so that all impacts may be disclosed and properly addressed.	Please refer to the Master Response. This comment fails to identify the "major state policy" to which it refers. That particular comment is too vague to allow for a substantive response. Please see the Response to Comment 100.

No.	Commenter	Comment	Response
120	Library	This is in response to the Notice of Completion for the Draft Environmental Impact Report for the Castaic Lake Water Agency Supplemental Water Project Transfer. The County of Los Angeles Public Library has reviewed the document and determined that this project will not have an impact on library services.	This comment is noted; no text revisions are required.
121	SCAG	The Draft EIR, in Section 5.0, Consistency with Adopted Plans and Policies, cited SCAG policies and addressed the manner in which the proposed Project is consistent with applicable core policies and supportive of applicable ancillary policies. This approach to discussing consistency or support of SCAG policies is commendable and we appreciate your efforts.	This comment is noted.

MASTER RESPONSE

TO ISSUES RAISED BY COMMENTERS REGARDING APPROPRIATE LEAD AGENCY TO PREPARE EIR AND THE RELATIONSHIP BETWEEN THIS EIR AND THE EIR FOR THE MONTEREY AMENDMENT

I. CLWA MUST BE THE LEAD AGENCY UNDER THE DOCTRINE OF THE LAW OF THE CASE.

The doctrine of the law of the case requires that CLWA be the lead agency for the Project. Under the doctrine of the law of the case, "Litigants are not free to continually reinvent their position on legal issues that have been resolved against them by an appellate court." (*Yu v. Signet Bank/Virginia* (2002) 103 Cal.App.4th 298, 312.)

The Court of Appeal held with respect to the prior EIR prepared by CLWA for the Project: "We have examined all of appellant's other contentions and find them to be *without merit*. If the *PCL*/tiering problem had not arisen, we would have affirmed the judgment." (*Friends of the Santa Clara River v. Castaic Lake Water Agency ["Friends"]* (2002) 95 Cal.App.4th 1373, 1387.) The Court of Appeal ordered that the trial court in that case retain jurisdiction over the Project and this subsequent EIR. (*Id.* at 1388.)

Thus, by deciding that there was no other legal defect with the prior Project EIR prepared by CLWA as the lead agency, and by retaining jurisdiction over this EIR in that case, the Court of Appeal resolved against subsequent legal challenges that CLWA is the proper lead agency for the Project. Indeed, the Court of Appeal ordered CLWA to act as the lead agency: "The trial court shall . . . retain jurisdiction until respondent certifies an EIR complying with CEQA . . .." (*Friends*, *supra*, 95 Cal.App.4th at 1388; See also the discussion of continuing jurisdiction of the court in Draft EIR ("DEIR") Section 1.2.1.)

II. CLWA MUST BE THE LEAD AGENCY BECAUSE IT HAS PRINCIPAL RESPONSIBILITY TO APPROVE AND CARRY OUT THE PROJECT.

CLWA must act as the lead agency because it has primary responsibility to carry out or approve the Project. The agency that has the primary responsibility to carry out or approve a project must be the lead agency, even if the project would be located within the jurisdiction of another public agency. (See Pub. Res. Code § 21067; 14 Cal. Code Regs. § 15051.) CLWA has the primary responsibility to carry out and approve the Project because CLWA will purchase, arrange for transport of, and use the Project water. (See DEIR Section 1.3 and Chapter 2.) The owner of the Project *res* is under mandate to act as the lead agency. (See *Friends of Cuyamaca Valley v. Lake Cuyamaca Recreation and Park Dist.* (1994) 28 Cal.App.4th 419, 428, *rev. denied*.) There is legal precedent for a local water agency acting as lead agency when it proposes to import supplemental water. (See *Temecula Band of Luiseno Mission Indians v. Rancho Cal. Water Dist.* (1996) 43 Cal.App.4th 425.)

As Section 1.1 of the DEIR indicates, CLWA has the principal responsibility for carrying out and approving the Project because a substantial portion of the Project occurs within CLWA's jurisdiction and substantially affects CLWA.

III. CLWA MUST BE THE LEAD AGENCY BECAUSE IT IS THE LOCAL AGENCY UNDERTAKING THE PROJECT.

CLWA must be the lead agency because it is the local agency undertaking the Project. The local agency undertaking a project must be the lead agency. (See Pub. Res. Code § 21152.) A local agency under CEQA is any public agency that is not a state agency, board or commission. (See Pub. Res. Code § 21062.) Thus, CLWA is a local agency. As explained in Sections 1.1 and 1.3 and Chapter 2 of the DEIR, CLWA will carry out the Project in that it is the major proponent of the Project and has assumed the primary task of effectuating the SWP water supply contract amendment.

Some of the comments to the DEIR suggest that CLWA lacks the institutional authority to undertake the Project because DWR must approve the delivery of the water through the SWP system. DWR is certainly a responsible agency because it must approve the transfer and execute amendments to the CLWA and KCWA SWP contracts. However, DWR cannot be the lead agency merely because it will approve the point of delivery for the Project. A state agency that has a role in approving or carrying out a local agency project must act as a responsible agency. (See *Bakman v. Department of Transportation* (1979) 99 Cal.App.3d 665, 678-679.)

In *Bakman*, the local agency submitting an application for a permit to expand an airport was held to be the lead agency, and the California Department of Transportation was held to be a responsible agency. It did not matter that the DOT had to consider the advantages and disadvantages to the public of the proposed expansion in acting to approve the airport.

DWR's role in the Project contrasts with DWR's role for the Monterey Amendment specified in *Planning and Conservation League v. Department of Water Resources* ["*PCL*"] (2000), 83 Cal.App.4th 892. In *PCL*, the Court of Appeal determined that the DWR was the appropriate lead agency for the Monterey Amendment because the Amendment involved major changes in DWR contracts with all 29 State Contractors, DWR changes in management and operation of the entire SWP system, DWR conveyance of the Kern Fan Element, and DWR facilitation of water transfers throughout the SWP system.

In contrast with *PCL*, the Project does not involve DWR conveying land, DWR changes in management and operation of the entire SWP system, major changes to statewide contracts, or DWR facilitating transfers among all contractors. As Sections 1.1, 1.3, 3.0 and Chapter 2 of the DEIR state, the Project, although requiring the use of SWP facilities, would involve a transfer to CLWA from WRMWSD through KCWA, its representative state contractor. The Project will take place within a limited geographic area and does not implicate the entire SWP water rights and supply framework. In this Project, DWR need only consider the capacity of a small portion of the SWP to deliver CLWA's newly purchased SWP contract water right.

The Project more closely resembles a recent water banking project between CLWA and Semitropic Water Storage District than the Monterey Amendment. Both the Project and the water banking project involve exchange of SWP water between two water contractors pursuant to a local project initiated and carried out by one of the State Contractors.

The recent Superior Court decision regarding that water banking project held that the local State Contractor agency, CLWA, was the appropriate lead agency under CEQA, even though DWR had a role in approving a point of delivery agreement and in facilitating the exchange through local changes in operation of the SWP. (See *California Water Network and the Friends of Santa Clara River v. Castaic Lake Water Agency* (2004), Ventura County Case No. CIV 215327.) The Superior Court in that case concluded: "Castaic is the agency most deeply involved in the planning and execution of this project. It is the appropriate lead agency as described in *PCL*, Public Resources Code Section 21067, and 14 Cal. Code Regs. 15014(a)." That case is currently on appeal.

IV. CLWA MUST BE THE LEAD AGENCY BECAUSE IT CANNOT DELEGATE ITS RESPONSIBILITY OVER ITS SWP CONTRACT RIGHTS.

Because CLWA is the party purchasing the SWP contract right pursuant to the Project, CLWA cannot delegate its review and consideration to another body. "Delegation is inconsistent with the purpose of the review and consideration function since it insulates the members of the council from public awareness and possible reaction to the individual members' environmental and economic values. Delegation is inconsistent with the purposes of the EIR itself." (*PCL*, 83 Cal.App.4th at 907, citing *Kliest v. City of Glendale* (1976) 56 Cal.App.3d 770, 779.)

In *PCL*, the Court of Appeal held that DWR could not delegate its responsibilities over execution of global, long term SWP contract amendments, Kern Fan Element conveyance, and statewide distribution of water because DWR had the appropriate statewide perspective and expertise for all of the elements of the Monterey Amendment. (*PCL*, 83 Cal.App.3d at 906.) In contrast, DWR is not primarily responsible for the elements of the Project, nor do all or even a majority of the Project elements require DWR's statewide perspective and expertise. CLWA has primary responsibility for purchasing, obtaining delivery of, and using the SWP contract rights pursuant to the Project. (See DEIR Chapter 2.) These are not matters requiring DWR statewide perspective and expertise, but are matters for which CLWA must stand accountable to its electorate.

As Section 1.1 of the DEIR indicates, CLWA has the expertise to implement the Project. CLWA has specific expertise to address growth inducement and growth-related impacts in its own service area, which are the primary impacts of the Project. CLWA is the agency with the greatest knowledge of local water supply issues and their relationship to planning decisions.

CLWA has been able to obtain the benefit of DWR's statewide perspective and expertise helpful to environmental analysis of the Project as a result of DWR's participation as a responsible agency. As responsible agencies, KCWA and WRMWSD have been actively involved in the development of the EIR and have provided input regarding baseline conditions and impacts to the WRMWSD service area, including impacts to agricultural resources, land use, air quality, water resources, and biological resources.

DWR comments on the DEIR confirm that DWR has been actively involved in the development of the DEIR: "DWR appreciates inclusion and consultation in the early stages of preparation of this DEIR." (Comment 5)

DWR comments on the DEIR also confirm that, from DWR's perspective, the DEIR has adequately addressed issues involving the SWP: "The [DWR] staff have reviewed the [DEIR] and found that the document adequately and thoroughly discusses the proposed project and its impacts. The DEIR provides a good discussion of the relationship between the 41,000 acre-feet Table A transfer and the current process for preparation of a new EIR for the Monterey Amendment. DWR notes that this DEIR adequately discusses the reliability of the SWP, pre- and post-Monterey Amendment conditions, future conditions, and SWP operations." (DWR Comments 1, 2 & 4)

With CLWA acting as lead agency, dissemination of information about the Project and the availability of the DEIR has been more extensive than CEQA requires. CLWA ensured that the DEIR, and notices of preparation of the DEIR, were widely distributed, sending approximately 250 copies to agencies (including water agencies), organizations, and individuals throughout the State. The notice and distribution list is included as Attachment A to this Master Response. DWR and WRMWSD cooperated with CLWA in the preparation of this notice/distribution list.

V. CLWA NEED NOT SUBORDINATE ITS LEAD AGENCY STATUS TO THE DWR PROGRAMMATIC ANALYSIS FOR THE NEW MONTEREY AMENDMENT EIR.

CLWA need not wait for or rely upon DWR's programmatic analysis in the new Monterey Amendment EIR. CEQA does not require a lead agency for a project to wait for another lead agency to prepare a programmatic EIR that is in the process of adoption; nor does CEQA require that a project EIR tier off a programmatic EIR. CEQA does not mandate that a program EIR be prepared even for a series of actions that can be characterized as one large project. (See 14 Cal Code Regs. 15168.)

The Court of Appeal in *Friends* did not require CLWA to tier off of or await adoption of DWR's new Monterey Amendment EIR. That Court of Appeal and appellant PCL merely suggested tiering as one course of action that CLWA could pursue if CLWA wanted to await action by DWR. (See *Friends*, *supra*, 95 Cal.App.4th at 1387-1388; See also DEIR Section 1.2.1.) The DEIR does not tier off either the old or new Monterey Amendment EIR. Except to the extent that it tiers off the 1988 CLWA Capital Program EIR, the DEIR stands alone as a project EIR.

There is no need for this project EIR to tier off the new Monterey Amendment EIR because the DEIR is for a stand alone project and because the DEIR contains thorough and independent analyses of the issues that *Friends* cited as lacking as a result of decertification of the original Monterey Amendment EIR. These issues include the potential environmental impacts that would arise as a result of KCWA transferring 130,000 acre-feet of Table A Amount, of which this 41,000 acre-feet transfer is a part. Unlike the 1999 Project EIR, the DEIR specifically identifies the environmental impacts to the SWP and associated facilities and to WRMWSD from the Project both with and without the Monterey Amendment. (See DEIR Sections 3.2, 3.4 & 3.15, particularly Section 3.15.2, and Appendices C & D.) Thus, the DEIR meets the requirements of CEQA to properly inform decision-makers and the public of the Project's environmental consequences.

The DEIR acknowledges use of a DWR modeling tool ("DWRSIM") that will generate slightly different water supply reliability estimates than would be generated from use of the more recent DWR modeling tool that DWR will use for the Monterey Amendment EIR ("CALSIM II"). Both models, however, use similar criteria to simulate SWP operations, and the results of both, while slightly different, are comparable for EIR purposes. (See DEIR Appendix D, Section 2.2.)

The DEIR publishes the water supply reliability results from both models and explains the differences and CLWA's reasons for using the DWRSIM model. (See DEIR Appendix D, Figures 2.1 & 2-2 and Section 2.2.) Thus, decision makers for this Project and public planning agencies interested in regional water planning are fully informed of the possible differences between modeling results as to the reliability of the amount transferred. In addition, the decision makers for this Project and public planning agencies are cautioned not to rely on past water deliveries as a guarantee of future deliveries. (See DEIR Section 1.1.)

The DEIR's use of the DWRSIM model to calculate the reliability of the transferred amount results in the DEIR considering slightly higher water supply reliability than would be the case if the CALSIM II model had been used. As a result, the DEIR analyzes slightly greater growth potential and environmental impacts than it would if the CALSIM II model had been used. However, these differences are not so significant as to cause a difference in analysis of significant impacts between DWR and CLWA (See Comments 2-6 by the DWR).

By using DWRSIM model results for its DEIR analyses, CLWA has used the model results that project the "worst case" growth rate (i.e., the greatest potential growth) and thereby the greatest potential environmental impacts. If one speculates that CALSIM II reliability figures will turn out to be more accurate, the need for the Project still remains, and the impacts will be less than described in the EIR. Thus, the public and decision makers are informed of the greatest possible environmental impact.

Because the DEIR does not rely on the CALSIM II model to project the reliability of the amount transferred, issues raised in various comments about the accuracy of the

CALSIM II model are not germane to this DEIR (those criticisms are discussed separately in the responses to particular comments).

However, the DEIR does use the CALSIM II model to calculate the current environmental setting. It was used for this purpose because it provides the best available estimate of SWP supplies at current levels of SWP demand. (See DEIR Section 3.15.2.2 and Appendix D, Section 6.1.2.2.)

The Settlement Agreement in *PCL* ("Monterey Settlement Agreement") does not require CLWA to wait for DWR certification of DWR's new Monterey Amendment EIR before CLWA can certify an EIR for the Project. (See DEIR 1.2.2.) Section III(C)(4) of the Monterey Settlement Agreement requires that the new Monterey Amendment EIR include, *inter alia*, analysis of the potential environmental effects relating to Attachment E Transfers and this Project.

Section III(C)(4) of the Monterey Settlement Agreement does not state that the new Monterey Amendment EIR must treat the Attachment E Transfers and this Project as new projects. Section III(C)(4) of the Settlement Agreement only states that the Monterey Amendment EIR must analyze the effects of the Attachment E Transfers and this Project "as actions that relate to the potential environmental impacts of approving the Monterey Amendments." Thus, Section III(C)(4) of the Settlement Agreement merely requires that the Monterey Amendment EIR consider the cumulative impacts of the Attachment E Transfers and the Project in its review of the Monterey Amendment.

Any claim that the Settlement Agreement requires either the Attachment E Transfers or this Project to be reviewed by the DWR as new projects as part of the new Monterey Amendment EIR is disavowed in the Settlement Agreement. Section III(D) states that the Attachment E Transfers are recognized as final. With respect to this Project and the *Friends* litigation that necessitated preparation of this EIR, Section III(E) of the Settlement Agreement states: "The Parties agree that jurisdiction with respect to that litigation should remain in that court and that nothing in this Settlement Agreement is intended to predispose the remedies or other actions that may occur in that pending litigation." One of the actions ordered by the Court of Appeal in "that pending litigation" was CLWA's certification of a new EIR (this EIR) for the Project. (See *Friends*, *supra*, 95 Cal.App.4th at 1388.) Thus, the Settlement Agreement is consistent with the present EIR process.

The parties to the Settlement Agreement acknowledged that DWR would not be required to act as the lead agency for the transfer of Table A Amounts between existing SWP Contractors. Sections I(D) and VII(D) incorporate by reference Attachment D Principles Regarding Public Participation Process in SWP Contract Negotiations. Paragraph 4 of the Attachment D Principles provides: "When DWR is a responsible agency, (e.g., when existing SWP Contractors agree to transfer entitlement between themselves), the public participation will be scheduled to facilitate coordination with the lead agency's CEQA process."

Section 4 – Changes to DEIR Text

4.0 CHANGES TO THE DEIR TEXT

Executive Summary and Chapter 1, Introduction

The following text from DEIR Page ES-4, lines 20-31, and DEIR Page 1-4, lines 13-23, should be deleted:

"It should be noted at this point that the Settlement Agreement concerning the PCL Litigation creates a specific exclusion for this Project from any prohibitions against transfers of State Water Project Table A Amounts by the Settlement Agreement. The exclusion states:

> With respect to Section III(c)(4)(b) regarding the Kern-Castaic Transfer, the Parties recognize that such water transfer is subject to pending litigation in the Los Angeles County Superior Court following remand from the Second District Court of Appeal (See Friends of the Santa Clara River v. Castaic Lake Water Agency 95 Cal.App.4th 1373, 116 Cal.Rptr.2d 54 (2002); review denied, April 17, 2002). The Parties agree that jurisdiction with respect to that litigation should remain in that court and that nothing in this Settlement Agreement is intended to predispose the remedies or other actions that may occur in that pending litigation."

The above text should be replaced with the following:

"The Monterey Amendment Settlement Agreement does not require that the new Monterey Amendment Program EIR be certified before an EIR for this Project can be certified, nor does it require that the EIR for this Project tier off the new Monterey Amendment Program EIR. The Monterey Amendment Settlement Agreement does not require that the new Monterey Amendment Program EIR serve as the EIR for this Project. Section III(C)(4) of the Monterey Amendment Settlement Agreement only requires DWR to analyze the potential impacts resulting from this Project and other transfers as they relate to the potential environmental impacts of approving the Monterey Amendment. Section III(E) of the Monterey Amendment Settlement Agreement clarifies that the Section III(C)(4) analysis is limited by remedies or other actions of the Los Angeles County Superior Court in *Friends I*, stating:

> With respect to Section III(C)(4)(b) regarding the Kern-Castaic Transfer, the Parties recognize that such water transfer is subject to pending litigation in the Los Angeles County Superior Court following remand from the second District Court of Appeal (*See Friends of the Santa Clara River v. Castaic Lake Water Agency 95 Cal.App.4th 1373, 116 Cal.Rptr.2d 54 (2002); review denied, April 17, 2002*). The Parties agree that jurisdiction with respect to that litigation should remain in that court and that nothing in this Settlement Agreement is intended to predispose the remedies or other actions that may occur in that pending litigation."

Table of Contents

Executive Summary

- Between 1990 and 1999, permanent crops increased from 30 percent to 38 percent of cropped land in Wheeler Ridge-Maricopa Water Storage District (WRMWSD). Between 1999 and 2001, they rose to 48 percent. Vineyards are the single most important permanent crop. Permanent cropped acreage has increased in both surface water and ground water service areas of the district.

- Because of the large capital costs for establishing a vineyard, grove, or orchard, the increase in permanent crop acreage suggests that farmers in the service area are confident that they will be able to consistently obtain the water necessary for their operations. The actions of WRMWSD have increased the reliability of water and helped offset the rising costs of SWP surface water. Growers are able to produce more labor-intensive, higher value crops.

- WRMWSD has diversified its water supply and management portfolio dramatically since the 1980s. The district's SWP entitlement remains an integral component of total supplies, but supplemental sources now provide a substantial drought buffer for the district.

- WRMWSD has invested in ground water recharge storage and recovery systems outside of the WRMWSD service area as well as distribution and pumping infrastructure in order to increase the reliability of water in dry years. Banking surface water when available or conjunctively using ground water in wet and normal years allows WRMWSD to have a more reliable water supply when normal demand exceeds supplies available from the SWP. This banking and reliability more than offsets any of the impacts of the 41,000 AF transfer of SWP surface water.

- The transfer of 41,000 AF of SWP water will have little or no impact on cropping patterns and production in WRMWSD. The district has taken adequate steps to insure that more reliable water supplies from various sources will be available at lower cost to offset the transfer. The transfer and resulting payment for the transferred water reduce the fixed costs of the unneeded SWP entitlement and thus reduce the financial burden to WRMWSD. The district is better able to continue to improve its water infrastructure and supply. Without this infrastructure and reliable supply, more lands will likely be removed from production temporarily or permanently.

- During the last 12 years, WRMWSD has experienced a significant shift in agricultural cropping patterns. Farmed land in the WRMWSD has varied from a low of 60,370 acres in 1991, a severe drought year, to a high of 94,499 acres in 1998. Crop acreage fluctuated by an average of 11.6 percent each year between 1990 and 2001. The principal factors causing the variations likely have included water availability, crop rotations, and crop prices.

- Annual crop acreage has declined, while acreage in permanent crops has increased. Annual crop acreage fell by 13,376 acres in the WRMWSD surface water service areas from between 1990 and 1999 and by a further 9,068 acres between 1999 and 2001. In the surface water service areas, cotton acreage declined by 15,534 acres between 1990 and 1999 and by a further 1,528 acres between 1999 and 2001. Over the same two periods in the groundwater service areas, annual crop acreage increased by 8,668 and decreased by 5,128, respectively.

- Many economic factors influence cropping decisions and resultant cropping patterns. Changes in crop prices, particularly for cotton, and the total of variable costs (including water prices), as well as strong demands for grapes and citrus, appear to have influenced the decisions of farmers in the WRMWSD regarding crop choices.

- As overall production costs increase, including those for water, cotton growers find it harder and harder to stay in production. Rotation crops such as grain and hay do not even cover variable costs in some years. Growers are better off to fallow lands than to continue production of these crops.

- Fallowing has been a regular part of cropping patterns in WRMWSD. Between 1991 and 1998, the amount of fallowed land decreased by 34,000 acres. Since 1998, fallowed acreage has increased by 11,600 acres. Fallowing is attributable to many different factors, including crop prices, cultivation practices, production costs, and others. Fallowing thus varies widely between years. From 1990 through 2001, the amount of land fallowed fluctuated annually by 34.9 percent, or 9,651 acres.

- During the early 1990s drought period, it became apparent that Department of Water Resources (DWR) announced water shortages could become a reality and that water costs would soar when water was not delivered. Following this period of drought impacts, WRMWSD experienced a significant shift of acreage to higher value crops such as fruits and vegetables and a reduction of acreage in lower value crops such as cotton, hay, and other field crops. The last two to three years appears to be a period of leveling out of new perennial crop plantings and increased fallowing.

- Fallowing has increased since 1998 even though State Water Project (SWP) deliveries, with the exception of 2001, have been relatively high. The increase is probably due to market conditions, particularly for cotton, as well as other economic and agronomic reasons.

- Total applied agricultural water within WRMWSD averaged about 251,000 acre-feet (AF) annually between 1990 and 1999 and about 259,000 AF annually between 1999 and 2001. Over those two periods, total WRMWSD deliveries from all sources averaged 158,000 AF and 168,000 AF annually, respectively. The remainder was supplied by on-farm ground water pumping, user input, or other water supplies available to farmers in the WRMWSD area.

- Before the 41,000 AF transfer, WRMWSD held a water supply contract for about 238,000 AF of SWP water. After the transfer, the remaining 197,000 AF of contract amount, with supplemental supplies, should leave the district comfortably able to meet demands in normal and wet years. Neither cost nor availability should be adversely affected in those years, and the transfer should not, of itself, cause an increase in fallowing.

- The WRMWSD supplemental water supplies were developed primarily to help meet demands during dry years. Those sources will more than make up for any dry year shortfall incurred as a result of the 41,000 AF of water transferred.

Introduction

Agriculture is the main industry in the Wheeler Ridge-Maricopa Water Storage District (WRMWSD) service area. Agricultural lands in this area are among the most productive in Kern County and the entire state. Water is a key input to agriculture here, and has been instrumental in the production of a variety of crops destined for both domestic and international markets. The cost and availability of various water sources have significant effects on farm profitability and survivability.

Over time, farmers in the service area have changed cropping mixes, adopted different rotations, and used different water sources for their operations. These changes are an outgrowth of the many factors incorporated into the decision-making framework used by farmers, some unique to each farm, others common to all.

This report considers the farm-level impacts of the 41,000 acre-feet (AF) transfer of State Water Project (SWP) entitlement from WRMWSD to Castaic Lake Water Agency (CLWA). The focus of the analysis is on whether the transfer will cause changes in agricultural practices, including additional land fallowing within WRMWSD. The report is presented in three sections. The first is an assessment of pertinent existing conditions within WRMWSD, including information on components of water supply and uses. The discussion also incorporates a review of crop acreages and use of various water sources over time. The second section describes the decision-making framework which farmers seeking specific economic objectives follow in determining which crops to plant and which inputs, including water, to use on these crops. This development follows widely-accepted principles of farm management and agricultural economics. The third section discusses the relationship of the transfer on agricultural operations within WRMWSD.

Existing Conditions

Cropping Patterns[1]

Crops grown within the WRMWSD service area had a farm-level production value of nearly $283 million in 2001 (see Table 1).[2] Grapes provided the greatest dollar value, at 31 percent of the total, followed by mixed produce and melons at 26 percent, citrus at 25 percent, and cotton at seven percent. Total value in 2001 was 6 percent greater than the comparable value in 1999, and the value in 1999 was 23 percent higher than that in 1990. The allocation of value among crops has also changed a great deal since 1990, when grapes accounted for just 18 percent of the total, mixed produce and melons 36 percent, citrus 11 percent, and cotton 20 percent. Because of the 1987-92 drought that so severely impacted Kern County and the entire San Joaquin Valley, the value of crop production in WRMWSD fell between 1990 and 1992 and then rose to exceed the 1990 value only by 1995.

Since 1990, net farmed land[3] in WRMWSD has varied from a low of 60,370 acres in 1991 to a maximum of 94,499 acres in 1998 (see Table 2). For the 12 years shown, the normal annual variation in net farmed land was 11.6 percent,[4] or about 9,700 acres. As shown in Figure 1, the general trend in net cropped acreage was positive until about 1999.[5] Similarly, the general trend in the acreage of annual crops was positive until about 1996, then notably

1 Cropping information for WRMWSD is taken from annual crop reports provided by the district for the years 1990 through 2001.

2 Based on crop acreages reported by WRMWSD and average price and yield data reported for Kern County by the Kern County Department of Agriculture.

3 Measured as total cropped less double-cropped land.

4 Measured as the coefficient of variation, calculated as the standard deviation divided by the mean. See Snedecor and Cochran.

5 A two-period moving average is used to reduce variation typical between years.

negative. In 1990, annual crops accounted for 70 percent of cropped acres.[6] By 1999, the annual crop share had fallen to 62 percent and by 2001 to 52 percent. Cotton, historically the predominant annual crop in WRMWSD, represented 61 percent of annual cropped land in 1990, but only 36 percent in 1999 and 37 percent in 2001. From its peak in 1996, land in annual crops fell 9,011 acres by 1999 and an additional 14,196 acres by 2001. Cotton accounted for nearly 80 percent of that reduction. Conversely, the acreage shares of mixed produce and melons rose from 31 percent in 1990 to 38 percent in 1999 and fell to 35 percent in 2001. The share of irrigated grains increased from zero in 1990 to 18 percent in 1999 and fell to 14 percent in 2001.

The negative trend for annual crops has been offset almost completely by the increases in permanent crop acreage. In 1990, permanent crops accounted for 30 percent of cropped land, with vineyards comprising 40 percent of the total, deciduous nuts 26 percent, citrus 23 percent, and deciduous fruits eight percent. In 1999, permanent crops accounted for 38 percent of cropped land, with vineyards 43 percent of the total, deciduous nuts 23 percent, citrus 27 percent, and deciduous fruits five percent. By 2001, permanent crops represented 48 percent, with vineyards at 44 percent of the total, deciduous nuts 21 percent, citrus 30 percent, and deciduous fruits five percent.

Table 2 shows fallowed land[7] ranging from a maximum of 51,620 acres in 1991 to a minimum of 17,649 acres in 1998. The spike in fallowed land in 1991 was attributable largely to the ongoing drought in California and sharply-reduced water supplies, together with higher costs of water from virtually all sources. Because of its different water sources, which are even more diversified today, WRMWSD was able to provide some water to farmers in 1991. Subsequently, fallowed acreage declined sharply until 1998 and has risen since then (see Figure 2).

Farmers fallow land for many reasons, both agronomic and economic. Agronomic reasons include the use of fallowing as part of crop rotations. Economic reasons include such factors as the market conditions and prices for the crops typically grown on the land and the cost and availability of production inputs, including water.

Without information from individual landowners, it is very difficult to distinguish between land that is fallowed temporarily and land that is removed from production either permanently or for a long term. The California Department of Conservation, which monitors land use with aerial photos taken every two years, reports previously productive, but

---

6 Calculated relative to total cropped land because some annual cropland is double cropped.

7 As shown in WRMWSD crop reports. Fallowing generally refers to temporarily removing land from production to conserve moisture or to control pests.

currently idle, land as fallowed for at least three monitoring cycles (that is, six years).[8] Ultimately, land may be fallowed for eight years before it is no longer considered to be in active agricultural use. Thus, it is not at all apparent that the increase in fallowed land with the WRMWSD service area since 1998 is attributable to a reduction in SWP entitlements within the district. Rather, the increase appears to be related more closely to crop markets and prices.

8 Molly Penberth, California Department of Conservation, April 30, 2003, personal communication.

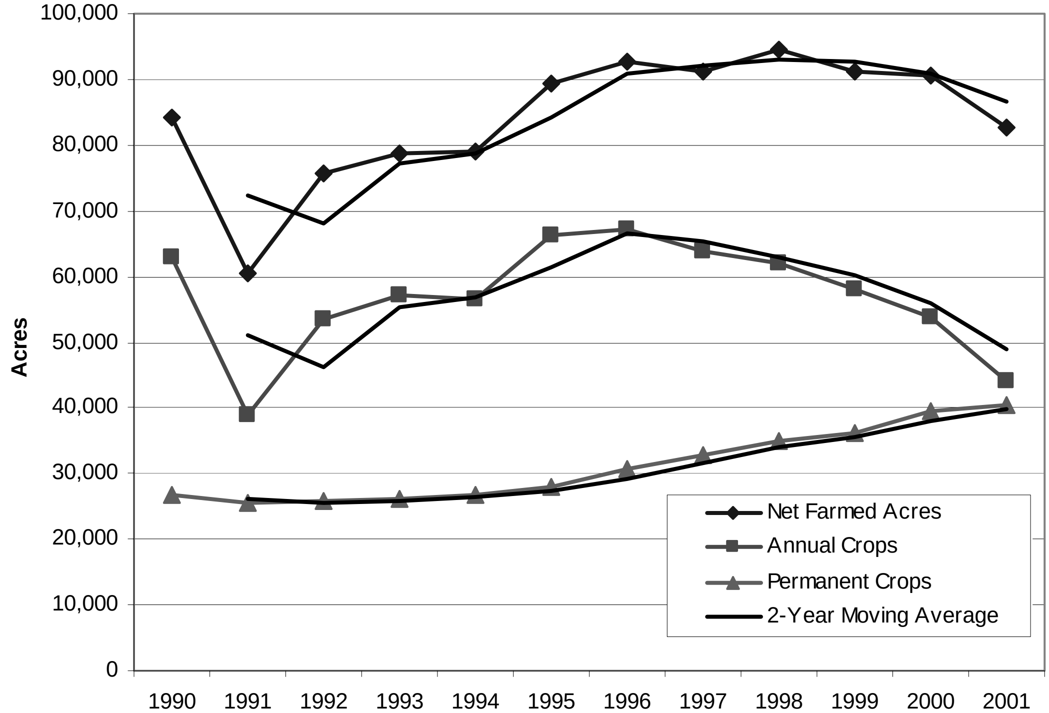

Figure 2
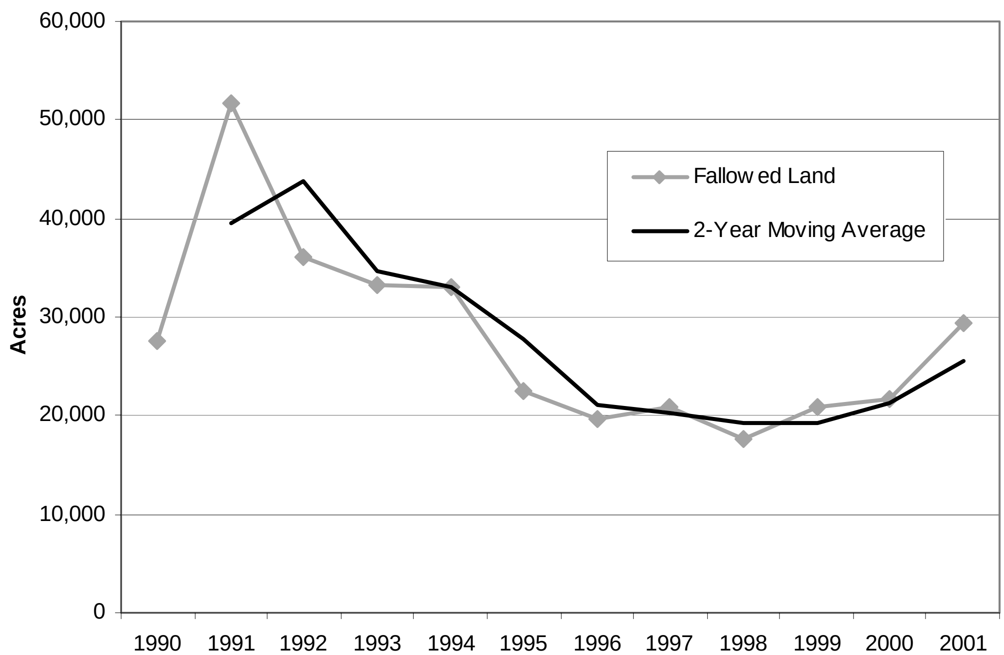
Fallowed Land, WRMWSD



Cropping Pattern Changes by Service Area

WRMWSD includes lands served by surface water or ground water or, in some cases, both. Cropped acreage in the surface water service areas (without exclusion of double cropping) fell by 5,850 acres between 1990 and 1999 and a further 5,885 acres between 1999 and 2001. Cropped land in the ground water areas increased 10,621 acres between 1990 and 1999 and fell 4,135 acres between 1999 and 2001.[9] The amount of annual crops in surface water areas fell by 13,376 acres between 1990 and 1999 and a further 9,068 acres between 1999 and 2001. For the two periods in the ground water areas, annual crop land increased by 8,668 acres and fell by 5,128 acres. The acreage of permanent crops rose in both surface water and groundwater service areas (see Figures 3 and 4).

The decline in annual crops and increase in permanent crops in surface water areas relates well to lower prices for some annual crops and higher water prices over the period. As discussed elsewhere in this section, cotton prices have fallen in both nominal and real terms since 1990, and it is no longer feasible to grow cotton in many parts of Kern County. Many cotton producers have been impacted by a "cost-price squeeze" quite common in agriculture.

The shift to permanent crops in the surface water service areas suggests that farmers in those areas are confident that they will be able to obtain water regularly either from within or outside WRMWSD, with or without the 41,000 AF of water under consideration. The capital investment for establishing an orchard, grove, or vineyard can easily exceed $8,000 per acre, excluding land, and farmers will not make those investments unless they are confident that they will be able to obtain adequate water for commercial production or, at minimum, keeping the trees or vines alive. While SWP water certainly remains an important part of the total WRMWSD supply, the SWP component of supply has been supplemented by the development and availability of several sources of supplemental water discussed elsewhere in this section.

---

9 Wheeler Ridge-Maricopa Water Storage District, various years, "Crop and Land Use Summary," Bakersfield. The changes also reflect, in part, the reclassification of lands within WRMWSD.

Figure 3

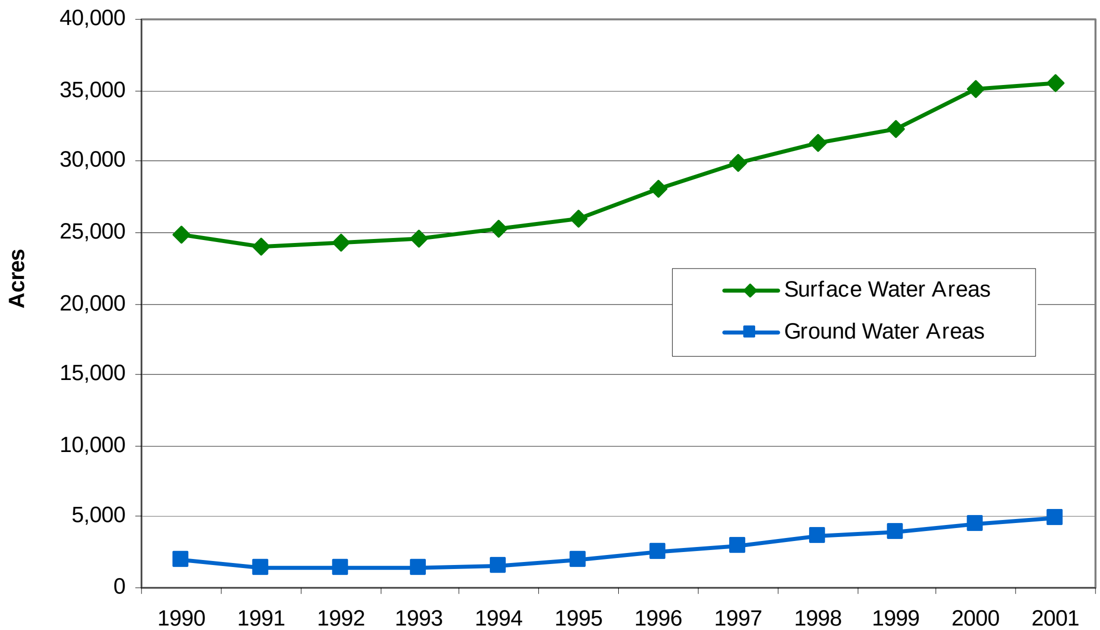
Permanent Crop Land in Surface and Ground Water Areas, WRMWSD



Factors Accounting for Cropping Pattern Changes

Changes in cropping patterns, whether from one type of annual crop to another or from annual crops to permanent crops, may be due to several factors. Some of the more important within WRMWSD may include:[10]

- Market conditions and crop prices;
- Input requirements and costs;
- Soil and micro-climate characteristics;
- Crop rotation requirements, including fallowing;
- Water availability and cost;
- Government programs; and
- Contracts with crop processors.

Absent detailed information from each farmer in an area, it is not possible to attribute changes in cropping patterns to any of these or other individual factors. However, changes in prices and production costs for key crops, particularly cotton, grapes, and citrus, and in water costs and availability appear to have played important roles.

Cotton prices have declined in both nominal and real terms since 1990. Acala cotton grown in Kern County[11] sold at an average farm price of $0.77 per pound in 1990. Yield averaged 1,200 pounds per acre, and gross revenue thus averaged $924 per acre.[12] In 2001, the last year for which data are currently available, the average farm price for Acala cotton grown in Kern County was $0.68 per pound. Yield averaged 1,342 pounds per acre, and gross revenue averaged $905 per acre.

While average per-acre gross revenue fell 2.1 percent between 1990 and 2001, costs of production have increased sharply and profitability has declined or disappeared for many growers. In 1995, average total costs to produce cotton in the San Joaquin Valley were estimated at $815 per acre, assuming a yield of 1,250 pounds of lint and application of 2.5 AF

---

[10] These are discussed in more detail in the section on farm-level decision making.

[11] Acala cotton has accounted for 76 to 93 percent of all Kern County cotton since 1990.

[12] Kern County Department of Agriculture.

of water at $50 per AF.[13] The total cost figure excludes a payment for management or risk. Average gross revenue for cotton that year in Kern County was reported to be $815 per acre.[14] Thus, the average gross revenue for cotton in 1995 would just cover all costs, but not cover a payment to compensate for management and risk. Moreover, WRMWSD delivered water costs that year were between $58 and $193 per AF, depending on the zone of the district to which the water was delivered.[15] Thus, all other factors unchanged, cotton production in WRMWSD that year would have generated losses of between $20 and $483 per acre, disregarding any compensation for risk or management.[16]

Current published costs are $1,002 per acre for Acala cotton, assuming a lint yield of 1,250 pounds per acre and 2.5 AF of water at $60 per AF, but also excluding payments for risk and management.[17] Under these conditions and based on current cotton prices (assumed at $0.70 per pound, including loan deficiency payments), gross revenue would exceed total costs by $61 per acre, but without a return for management or risk. However, WRMWSD delivered water costs ranged from $89 to $230 per AF in 2001 and are expected to range from $101 to $260 per AF for all of 2002.[18] Clearly, cotton production is infeasible in parts of WRMWSD, and the result has been a continued shift from cotton to other, higher-profit crops

Many factors may affect the rate at which farmers change their crop mix. First, the market demands for fruits, nuts, and vegetable crops relative to supplies may signal that additional plantings of those crops would have adverse effects on prices. Second, processing capacity and the unavailability of processor contracts may limit the amount of vegetable crops such as tomatoes a farmer chooses to grow. Third, field and grain crops, while sometimes unprofitable in isolation, remain important parts of diversified crop rotations. Fourth, the crop history and risk characteristics of farmers may reduce the attraction of changing established cropping patterns.

16 It is acknowledged that every farm is unique, characterized by soil type, debt levels, water sources and other factors. Moreover, acreage data show that cotton is clearly still profitable on some farms in WRMWSD. However, the sharp declines in cotton acreage since 1990 indicate that the crop is less profitable or unprofitable in many parts of the district.

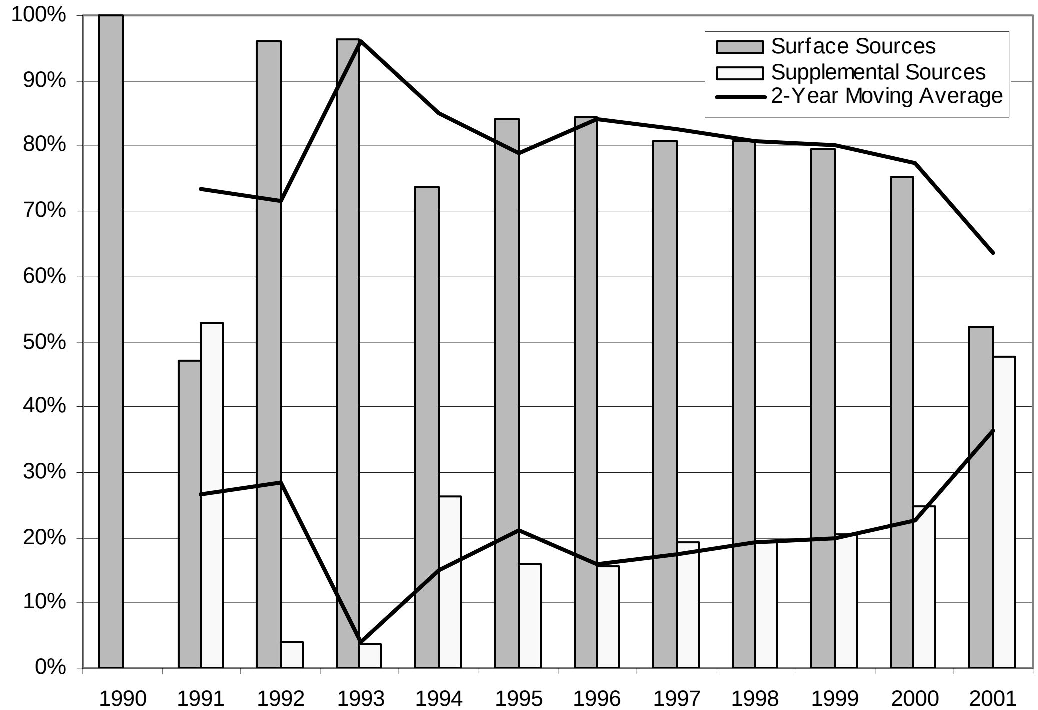
Water Sources and Costs

WRMWSD has a contract for SWP water through Kern County Water Agency and regularly provides that water to farmers as supplies permit. However, WRMWSD has also developed district wells and has access to other water sources such that its “water portfolio” is much more diversified today than it was in the late 1980s or early 1990s. Much of this diversification was in response to the nearly complete abrogation of the State of California’s responsibility to provide a reliable water supply from the State Water Project, aggravated by the effects of the 1987-92 drought.

Several individual sources collectively comprise the “supplemental water.” These include district wells, Blanco Rosa Improvement District wells, Kern Water Bank, Pioneer Project, Berrenda Mesa project, and miscellaneous supplies. Figure 5 shows that these alternative sources have become an increasingly-important component of total WRMWSD potential water availability. The two-period moving average trend line is clearly upward sloping, while that for traditional surface sources is declining. It should be noted that the data on which the figure is based include potential surface and supplemental water supplies rather than actual deliveries. Potential surface supplies are calculated as the sum of Article 21 water, carryover, user input, and the product (SWP Entitlement * Percentage of SWP Allocation) for each year.

Figure 5
Surface and Supplemental Water Sources, WRMWSD



Water Use

WRMWSD maintains records for all water deliveries it makes each year. It does not obtain information on ground water pumping by individual farmers. Thus, total water use within the district for any given year is not a single number that can be taken from a report. Bookman-Edmonston Engineering developed average applied water requirements for crops grown in WRMWSD.[19] For this report, estimates of total applied water within WRMWSD were developed by using these figures and multiplying those rates by acreages taken from the annual WRMWSD crop reports. The application rates used are shown in Table 3. The estimated applications, total WRMWSD deliveries, and estimated water applied, but from other sources, are shown in Table 4.

For the period from 1990 through 1999, total annual deliveries by WRMWSD averaged 158,056 AF. From 1999 through 2001, they averaged 168,335 AF. Based on the application rates shown in Table 3 and the crop acreages shown in Table 2, WRMWSD deliveries accounted for about 63 percent of total water applied to crops in the service area from 1990 through 1999 and 65 percent from 1999 through 2001. It should be noted that the estimated applied water figures in Table 4 represent potential applications and assume that farmers were able to obtain all required water in each year. For years in which all water supplies were limited (e.g., 1991), the applied water figures shown overstate actual applications.

Table 3
Average Applied Water Requirements for Various Crops Grown in WRMWSD

Crop	Average Applied Water Requirement (Acre-feet per acre)
Cotton	3.00
Sugar beets	4.20
Grains	1.35
Green feeds	5.00
Mixed produce	2.20

1/ Assumes supplies available regardless of source.

Total water applied within the WRMWSD service area fell from an estimated 277,527 AF in 1997 to 244,303 AF in 2001. Applied water for cotton fell almost 49,000 AF, mixed produce fell 6,900 AF, and melons fell 3,700 AF, paralleling reported acreage declines for those crops. In contrast, applied water on all permanent crops except deciduous fruits increased.

Decision-Making by Farmers

The data shown in the previous section reflect the combined effects of innumerable decisions made by farmers in the WRMWSD service area each year. Farm-level decision making in WRMWSD and every other agricultural area is a continuous process that adheres to and at times departs from traditional economic theory and models.

Farmers operate, more than most other industries, in an environment closely aligned with the "purely competitive" model of economics.[20] Agriculture includes thousands of producing units all making decisions independent of each other, virtually all are price takers, all have access to good information about markets and prices, and all, or nearly all, are trying to earn as much profit as they can from their operations.

There are extensive domestic and international influences on agriculture. Domestically, the price of natural gas affects fertilizer prices, the price of crude oil affects costs of gasoline and diesel fuel, interest rates affect the cost of operating loans, and economic growth affects consumer demands for all types of products. Agriculture is also subject to many influences from the global economy, evident in the tariffs in the U.S. and other countries on agricultural imports, the increasing production of such crops as cotton and deciduous nuts in Asia, and fluctuating exchange rates.

The decision-making framework which farmers must employ for their operations therefore includes considerations well beyond the farm gate. The results are indicated by decisions such as:

- Crops to plant and when;
- Inputs used and in what combinations;
- When and how to acquire or sell resources;
- When and where to sell harvested crops; and
- When to adopt new technology.

---

[20] See Henderson and Quandt.

Profit Maximization

One of the key assumptions in agricultural economics and farm management is that farmers attempt to use resources in a way that will maximize the profit of their operations.[21] An expanded form of that assumption is that farmers, with limited capital, attempt to allocate resources to their land in order to maximize profit across all crops they grow. There are many combinations of inputs which farmers can use in their operations, reflecting opportunities and costs. For example, weeds can be controlled chemically or with manual labor. Seeding and harvesting can be accomplished mechanically or by hand. Land preparation and fertilizing can be undertaken by the farmer or performed by custom operators.

In attempting to maximize profits, farmers weigh the tradeoffs and combine inputs in such a way that, at the margin, the value of product produced with each unit of input is the same for all inputs. All other factors unchanged, so long as the "value of marginal product" is greater for one input than for others, it is rational for the farmer to use at least one more unit of that input because the revenue from the product produced with that unit will exceed the cost of the input.[22] It is reasonable to assume that this framework is applicable not only to such inputs as fertilizer and chemicals, but also to water.

Crop Rotations and Profit Maximization Over Time

The decision-making framework is somewhat more complicated for the more realistic situation of farming continuously over time rather than in many separate single-year periods. This is particularly true for trees and vines, which take several years to mature and then remain productive for many years. However, for farmers growing several annual crops, a realistic goal would be to maximize profits over a crop rotation. Rotations generally include a sequence which alternates a variety of crops. Rotations may involve several crops and cover a period of several years. Accordingly, crop rotations may have a direct effect on the cropping pattern data reported for a given area.

The purposes of rotations include rebuilding soil nutrient levels, reducing pest concentrations and disease problems, and enhancing soil organic matter. It has been demonstrated that continuously planting the same crop on land causes the population of soil borne pathogens to

---

[21] See, for example, Heady and Kay and Edwards.

[22] It is recognized that not all farmers are in business to maximize profits and do not have, at all times, the information possibly relevant to efficient decision making. However, given the unavailability of information on alternative goals, it is usually assumed that farmers are in business to maximize their profits. See Heady.

increase.[23] Planting crops that are not hosts helps to reduce the populations of those pathogens. Plants which belong to the same family or class of plants (e.g., broadleaf) often share similar pest problems. Thus, effective rotations must incorporate crops which are not closely related.

Some of the factors which affect the rotations used by farmers include the following:[24]

- Cropping history;
- Grower experience;
- Input requirements for crops;
- Compatibility of crops with existing equipment complement and with labor;
- Existing array of pests; and
- Value of crop and market conditions.

Cotton has traditionally been the core crop for rotations in many parts of Kern County. Historically, rotations included cotton and small grains, both grown for commercial sale.[25] More recently, however, small grains have not been grown as extensively for commercial sale because of low crop prices.[26] They are still grown for silage. Other crops more typically included in cotton rotations are tomatoes, onions, melons, carrots, and alfalfa. Typical rotations might include:

- Two years of cotton and one year of tomatoes or melons;
- Two years of cotton, one year of tomatoes or melons or onions, and three years of alfalfa; and
- One or two years of cotton, three years of alfalfa, one year of tomatoes or melons or onions or carrots, and one year of small grain.

---

23 See Nunez.

24 University of California Cooperative Extension, 1995.

25 Brian Marsh, University of California Cooperative Extension, Bakersfield, March 26, 2003, personal communication.

26 Between 1996 and 2001, farm-level barley prices fell from $147 per ton to $84.40 per ton, while those for wheat fell from $168 per ton to $112 per ton. See Kern County Department of Agriculture.

By incorporating small grain and comparable crops into rotations, farmers sometimes appear to be growing economically-inefficient crops. However, the use of low-return crops such as small grains in rotations often reflects agronomic rather than purely economic considerations. The value from these crops would be reflected in better soil conditions and higher yields for other rotation crops in subsequent years. Thus, because of rotations, profit maximization must be viewed from a multi-year rather than a single-year perspective.

Fallowing may be an integral part of crop rotations. Fallowing, with a cover crop, may offer efficient opportunities to rebuild soil organic matter and conserve soil moisture. In addition, farmers may fallow some of their land in order to divert irrigation water usually used there to other, more productive parts of their farms. Farmers may also fallow land in order to be eligible for provisions of various government farm programs or as a component of reduced-tillage strategies.

Table 2 includes data on fallowed land, as reported by WRMWSD. Between 1990 and 2001, an average of 27,827 acres were fallowed within the district. Variation between years averaged plus or minus 9,651 acres, and that variation relative to the mean was 34.7 percent. Thus, over a three-year period, the change in the amount of land fallowed could range from (9,651) to 28,953 acres. Consequently, because so many independent farm-level decisions account for fallowed acreage for the entire district, it is impossible to attribute the increase shown since 1998 to any single factor, whether changes in water supplies, crop prices, input costs, or any other.

Effects of Water Costs and Availability

As noted previously, changes in measured cropping patterns for an area may be due to a variety of factors, such as market conditions, crop prices, government programs, contracts with crop processors, and soil and climate characteristics. For farmers in WRMWSD and throughout the San Joaquin Valley, the availability and cost of water are also critical factors in decisions on which crops to grow and thus in reported cropping patterns. As water reliability is reduced or water costs increase, economic theory as well as reported data suggest that farmers will adjust their crop and input choices to reflect the greater relative scarcity or cost of the resource.

For SWP water, both factors are likely important. Reliability of SWP water was addressed in a recently-completed report, which projected likely delivery capability of the system through 2021.[27] The key findings were that:

---

[27] California Department of Water Resources, 2002.

- In 75 percent of the years, the annual water delivery of the SWP is estimated to be at least 66 percent of full Table A deliveries

- In 50 percent of the years, annual water delivery is estimated to be at least 83 percent; and

- In 10 percent of the years, annual water delivery is estimated to be at least 98 percent.

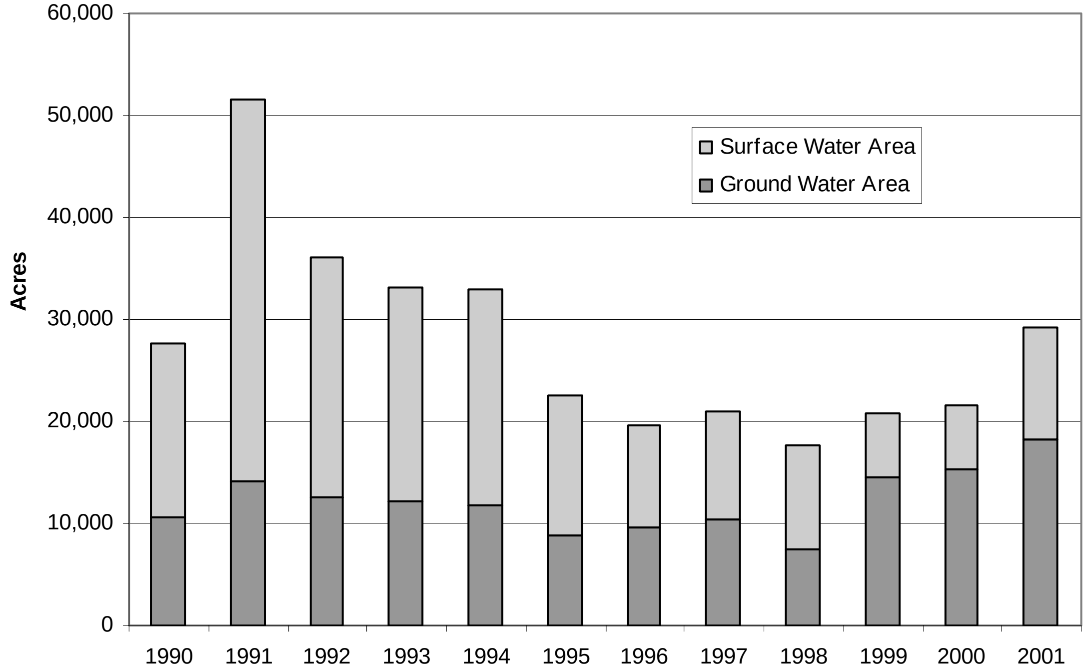
Moreover, costs of SWP water and other key inputs have risen, in some cases to the point that uncertainties over water deliveries, crop prices, and other key variables have caused some farmers to change their rotations and crop selection. The shift from annual crops, particularly cotton, to permanent crops in WRMWSD likely reflects this behavior. As discussed previously, cotton production is no longer feasible for many farmers. Similar shifts in ground water service areas likely reflect the increased costs of production, including higher energy costs for pumping.

Figure 6 shows the amount of fallowed land in WRMWSD. As shown, fallowed acreage peaked in 1991 because of severely-limited water supplies during the drought. By 1995, net cropped acreage had reached its 1990 level, and the amount of land fallowed had fallen to a more representative level. Prior to 1998, most of the fallowed land was in the surface water service areas. Since then, an increasing amount of fallowed land has been in ground water service areas. It is likely that some land has been fallowed for longer periods or idled in both surface water and groundwater service areas more recently because of low crop prices. In particular, the average Kern County price for Acala cotton fell from $0.84 per pound in 1995 to $0.68 per pound in 2001.[28] Over that same period, the average Kern County price for Pima cotton fell from $1.28 per pound to $0.86 per pound. Average Kern County prices for barley and wheat peaked in 1996, then fell, respectively, from $147 to $84.40 per ton; and from $168 to $112 per ton. Clearly, many farmers during this period realized that they would be unable to cover even variable production costs and very likely decided to fallow rather than plant crops.

There is no clear relationship between SWP water deliveries and fallowed land in WRMWSD. While SWP deliveries fell from 1996 to 1998, the amount of fallowed land in surface water areas decreased rather than increased. Between 1998 and 2000, SWP deliveries rose, yet the amount of fallowed land increased. Both sets of data indicate that fallowing decisions by farmers have not been based on SWP availability. If SWP water were the only irrigation source in WRMWSD, it would be only logical that as SWP deliveries fell, fallowing would increase. However, because of the diverse water supplies available to irrigators in the district, that relationship is not valid.

[28] See Kern County Department of Agriculture.

Figure 6
Fallowed Land in Ground Water and Surface Water Service Areas, WRMWSD



Results

This section evaluates the expected effects on agricultural practices, including land fallowing, of the 41,000 AF transfer of SWP water from WRMWSD. It draws from the discussion of farm-level decision making and from a review of data presented throughout the report. The approach utilized to estimate the impacts relies on a review of long-term water demands in WRMWSD and of other data previously presented. Discussion includes the expected effects of the transfer during normal and wet years and in dry years on district supplies and costs and on farmer responses.

Table 4 shows that total WRMWSD deliveries of water from all sources since 1990 have varied from a minimum of about 65,000 AF in 1991 to a maximum of nearly 203,000 AF in 1996. Table 4 also shows that estimated total applied water requirements have ranged from about 187,000 AF in 1991 to nearly 278,000 AF in 1997. Estimated total water applied using all water sources fell by 13,125 AF between 1997 and 1999 and by an additional 20,099 AF between 1999 and 2001. Much of this decline is likely attributable to reductions in planted acreages of cotton and other annual crops for which prices dropped so dramatically beginning in the mid 1990s. From 1990 through 1999, WRMWSD deliveries accounted for an average of 63 percent of total applied water. From 1999 through 2001, they accounted for 65 percent.

Prior to the 41,000 AF transfer, WRMWSD had a water supply contract to Kern County Water Agency for Table A amount of about 238,000 AF of SWP water. In normal or wet years, the 41,000 AF is in excess of district needs. It is therefore reasonable to assume that in those years, the transfer would have no or minimal adverse effects on overall water supply. Moreover, the water is in excess of district needs in dry years because of the supplemental sources to which WRMWSD has access. Moreover, in wet, normal, or dry years, irrigator water costs would not be adversely affected by the transfer. .Therefore, because neither the quantity nor cost of district water should be affected adversely, the transfer should have very limited, if any, impacts on land fallowing..

In a critically-dry year or series of such years, the unavailability of part of the WRMWSD SWP contract amount may contribute to a minor mismatch between water supply and demand. If overall water costs increase, there may be some farm-level impacts. WRMWSD has jointly used several of its supplemental sources only in 2001. The variable and fixed costs (excluding capital costs) for that year did not differ substantially from SWP costs over the previous five years. If the costs in 2001 are representative, the incremental impacts of the transfer on delivered water costs to farmers should be minor. The amount of land fallowed in this dry year scenario, including the transfer, should not be materially different from the normal variation in cropped and fallowed acreage between years

Finally, it should be noted that the transfer discussed in this report is part of the broad WRMWSD strategy of increased efficiency and development and use of the sources of water which are most compatible with that strategy. In particular, by selling unneeded SWP water supplies, WRMWSD is able to avoid the carrying costs for that water even in years when it is not needed. Overall, the water supplies from the supplemental sources more than offset the reduced SWP Entitlement and, when the carrying cost of holding excess SWP entitlement is considered, at a lower cost.[29]

Attachment A - Tables Included in the Responses to Comments

Table A-1. Projected Future Water Supplies and Demands in Average Hydrologic Conditions for the CLWA Service Area
(all values in AF)

Year	*Projected Total Average Year Supply (AF)*[1]	*Projected Total Average Demand*[2]	*Projected Total Average Supply Less Total Average Demand*
2005	114,300	75,100	39,200
2010	114,300	82,400	31,900
2015	114,300	91,600	22,700
2020	114,300	102,500	11,800

Note: Refer to Tables 3.15-7 and 3.15-9 in the Draft EIR for additional detail.

1. Includes Table A Amount, SWP flexible storage, Semitropic Storage (24,000 AF stored in 2002), and groundwater sources (Alluvial Aquifer and Saugus Formation). Does not include additional 35,000 AF of SWP Table A water stored in Semitropic in 2003. Table A values based on current Table A Amount of 95,200 AF (which includes the Project), and percentages for Table A deliveries from DWR's SWP Delivery Reliability Report (DWR 2003b). The average year supply is the average amount of water available based on DWRSIM model results over its entire period of hydrologic record.
2. Includes municipal and industrial, other demands including irrigated agriculture and miscellaneous uses, and projected conservation.

Table A-2. SWP Surplus Water[1] Types

Without Monterey Amendment (Including With Implementation of Article 18(b))	*With Monterey Amendment*
Scheduled surplus water - Water that DWR determined to be available, in addition to Table A supplies, which was scheduled for delivery throughout the year (in the same manner as Table A supplies). This water was generally available only during the early years of the SWP (when Contractor demands for Table A water were low).[2]	Category deleted as part of the Monterey Amendment. (Given increased Contractor demands through time, this water is physically no longer available.)
Unscheduled surplus water - Water that DWR made available when water and capacity were available in excess of SWP storage needs and Table A supplies. This water is only available for limited time periods, generally only in the winter or early spring when Contractors demands are low, and only under specific conditions that do not occur on an annual basis.	**Article 21 water -** Same as unscheduled surplus water. Article 21 water was defined under the Monterey Amendment as "interruptible water" but is more commonly referred to as "Article 21 water."

1. Surplus water is SWP water that can be made available to Contractors when water and capacity are available in excess of SWP storage needs and Table A supplies. See above for terminology for and descriptions of specific types of surplus water. Note that surplus water terminology changed with implementation of the Monterey Amendment.
2. Under the With Implementation of Article 18(b) scenario, scheduled surplus water would once again be available because, with Table A Amounts reduced to a new minimum project yield, water supplies would once again be available in excess of reduced Table A Amounts.

Table A-3. Comparison of DWRSIM Model Results with the SWP Delivery Reliability Report for the 41,000 AF Table A Amount

(All values in AF and rounded to the nearest 100 AF)

	Average Year[1]	*Single Dry Year*[1]	*Multiple Dry Year Period*[1]
Current Conditions (1998 or 2001)[2]			
DWRSIM Results (With Monterey Amendment)[3]	34,400	9,200	18,100
SWP Delivery Reliability Report[4]	29,400	8,000	14,800
Difference	**5,000**	**1,200**	**3,300**
Future Conditions (2020 or 2021) [2]			
DWRSIM Results (With Monterey Amendment) [5]	32,000	9,200	17,600
SWP Delivery Reliability Report[4]	30,600	8,200	15,000
Difference	**1,400**	**1,000**	**2,600**

1. The average year supply is the average amount of water available based on DWRSIM model results over its entire 73-year period of hydrologic record. The single dry year supply is the supply available in the single year with the lowest total SWP deliveries based on DWRSIM model results (1977). Multiple dry year period supply is the average amount of water available over the four consecutive drought years of 1988 through 1991 based on DWRSIM model results.
2. Current conditions for the DWRSIM model results and the SWP Delivery Reliability Report are 1998 and 2001 conditions, respectively. Future conditions for the DWRSIM model results and the SWP Delivery Reliability Report are 2020 and 2021, respectively.
3. Based on water deliveries from DWRSIM study 1995D06E-CALFED-771. This study used 1998 DWR estimates of then-existing SWP Contractor demands.
4. Values based on DWR SWP Delivery Reliability Report results and applying the same methodology suggested by DWR in its report.
5. Based on water deliveries from DWRSIM study 2020D09C-CALFED-786.

Table A-4. Permanent Table A Transfers Completed Under the Monterey Amendment Provisions (Article 53)

Section 1: Executive Summary

To be provided with Final Recycled Water Master Plan.

Section 2: Introduction

A Reclaimed Water System Master Plan for the Castaic Lake Water Agency (CLWA) was completed in 1993. This section summarizes the significant developments that have occurred since the preparation of the earlier plan, discusses the objectives of this Master Plan, and provides a brief overview of the methodology.

2.1 Background

CLWA has a contract with the State of California to purchase water from the State Water Project (SWP) and wholesale it to four domestic water purveyors in the Santa Clarita Valley. The imported water is delivered to Castaic Lake through SWP facilities. From Castaic Lake, which serves as the terminal reservoir of the SWP's West Branch, it is treated at CLWA's Earl Schmidt Filtration Plant or Rio Vista Filtration Plant and delivered to the domestic water purveyors through transmission lines owned and operated by CLWA.

The four water purveyors primarily serve municipal and industrial (M&I) customers. In normal years, approximately 50 percent of the M&I demand within CLWA's service area is met with imported water. However, the reliability of the SWP supply is subject to the availability of the water (i.e., precipitation and snowpack of the present and past years) and deliveries can be curtailed. When sufficient imported water is not available, the balance is met with local groundwater provided by the purveyors.

While the available groundwater is limited, it is anticipated that water demands will continue to increase. Accordingly, additional reliable sources of water are necessary to meet projected water demands. CLWA recognizes that recycled water is an important and reliable source of additional water.

The Sanitation Districts of Los Angeles County (LACSD) own and operate two water reclamation plants, Saugus Water Reclamation Plant (WRP) and Valencia WRP, within the CLWA service area. The water is treated to tertiary standards and discharged to the Santa Clara River. The Newhall Ranch development is also planning to construct a water reclamation facility, and non-potable water from this source may be incorporated into the CLWA recycled water system. Additionally, Berry Petroleum has expressed interest in treating oil field produced water for sale to CLWA for non-potable uses. Oil field produced water is a by-product of petroleum extraction. Also, treated perchlorate-contaminated groundwater may serve as a temporary source of non-potable water during the 1 to 2 year California Department of Health Services (DHS) demonstration period for the treatment facility. By utilizing the effluent from the WRPs, oil field produced water, and treated perchlorate-contaminated groundwater for irrigation and other non-potable purposes, CLWA can more efficiently allocate its potable water and increase the reliability of water supplies in the Santa Clarita Valley.

2.2 Significant Developments

Since the preparation of the previous Master Plan, the CLWA service area has experienced substantial growth. In addition to the changes in population and development in the Santa Clarita Valley, the following major developments have changed the assumptions for the Master Plan, necessitating this update:

- The use of treated effluent from the Saugus and Valencia WRPs is subject to the instream water use requirements of critical habitat along the Santa Clara River. Accordingly, it is assumed that only the portion of the effluent attributable to growth will be used, unless a habitat analysis indicates that use of a greater quantity of the effluent will not create adverse impacts.

- Oil field produced water from Placerita Canyon has been identified as a potential source of water for recycled water use.

- Several wells near the South Fork of the Santa Clara River have been identified as being contaminated with perchlorate. A centralized treatment facility is planned that will provide potable quality water. During the demonstration period required by DHS, the treated water may be available for recycled water use.

- The proposed Newhall Ranch development includes a wastewater reclamation plant and recycled water system. It would be desirable to integrate these facilities into CLWA's recycled water system.

- In addition to considering large aboveground reservoirs for seasonal storage, the concept of aquifer storage and recovery (ASR) is evaluated.

2.3 Objective

The primary objective of the Recycled Water Master Plan is to update the 1993 Reclaimed Water Master Plan to consider the significant developments affecting recycled water sources, supplies, users, and demands so that CLWA can develop a cost-effective recycled water system.

2.4 Development of the Plan

The information developed in this Master Plan update is largely drawn from the 1993 Master Plan, supplemented with contacts with CLWA, LACSD, local water purveyors, the City of Santa Clarita, the County of Los Angeles, oil company representatives, and potential water users. Additionally, analysis and computer modeling were performed.

Potential existing ~~and future~~ recycled water users were identified from the 1993 Master Plan and updated through contacts with the local purveyors and the City of Santa Clarita. Water demand characteristics, ~~including~~ time-of-use, were assessed through discussions with potential users. Through data analysis and computer modeling, the Master Plan was updated with a revised cost-effective recycled water system. Construction costs were estimated and a construction schedule was prepared.

2.5 Master Plan Organization

This report is organized as follows:

- Section 1, Executive Summary, summarizes the contents of the Recycled Water Master Plan.

- Section 2, Introduction, provides background information, introduces the report, and explains its structure.
- Section 3, Land Use, discusses the existing and projected land uses within the CLWA service area.
- Section 4, Existing and Projected Potable Water Supply and Demand, discusses the existing and projected water supply and demand for potable purposes, which necessitates the need for recycled water to serve non-potable demands.
- Section 5, Regulatory Requirements, discusses the federal, state, and local regulations addressing recycled water production, discharge, distribution, and use to protect public health. There are additional regulations that are relevant to oil field produced water, use of impaired waters, such as treated perchlorate-contaminated groundwater, and ASR.
- Section 6, Recycled Water Sources, presents an overview of water recycling facilities, flow, and quality in the Santa Clarita Valley. It also covers other potential sources of water for the recycled water system, including treated perchlorate-contaminated groundwater and treated oil field produced water.
- Section 7, Potential Recycled Water Constraints, provides a brief discussion of the issues that limit the usage of recycled water in the CLWA service area. Issues addressed include Santa Clara River hydrology, the riparian habitat, the endangered species, potential impacts of the proposed recycled water project on stream flows, and water rights issues.
- Section 8, Market Assessment for Recycled Water, identifies potential recycled water users within the CLWA service area and estimates annual demand, peak monthly demand, peak daily demand, and the hourly distribution of water demand during peak months.
- Section 9, Seasonal Storage Opportunities, examines alternatives for addressing the variations in seasonal supply and demand of recycled water, including ASR and aboveground storage.
- Section 10, Recommended Recycled Water System, discusses the planning criteria for system components, presents the recommended infrastructure of the recycled water system, and describes the modeling process used to size facilities. Costs are also presented in this section.
- Section 11, Permits and Approvals, focuses on permit requirements, other institutional issues, and the requirements of the California Environmental Quality Act (CEQA).
- Section 12, Funding and Financing Opportunities, presents a plan for financing the proposed recycled water system. Discussion of financing options, water rate policy, and connection fees is included.
- Section 13, Implementation Plan, presents a plan for implementing the recommended system, including phasing and implementation schedule.

Section 3: Land Use

To identify an appropriate service area for the recycled water distribution system, information regarding land use is important. This section describes the planning documents that govern land use in the Santa Clarita Valley and presents information regarding the existing and projected land uses within the CLWA service area.

3.1 General and Specific Plans

The CLWA service area encompasses approximately 195 square miles within the upper Santa Clara River Basin, much of which is known as the "Santa Clarita Valley," as shown in Figure 3-1. The majority of the CLWA service area is in Los Angeles County, but approximately 20 square miles in the westerly part of the service area extends into an unincorporated area of Ventura County. As shown on Figure 3-2, the CLWA service area includes the City of Santa Clarita and the unincorporated communities of Castaic, Valencia, Saugus, Canyon Country, Newhall, and Mint Canyon, among others.

General Plans have been prepared by the City of Santa Clarita, Los Angeles County and Ventura County, which outline the ultimate land use development anticipated for their respective planning areas. There are also several Specific Plans governing land use in portions of the CLWA service area. The City of Santa Clarita General Plan was adopted in 1991, with some of the elements updated more recently. The land use element has not been updated since 1991. Los Angeles County amended its General Plan for the unincorporated areas of the County in 1993. The Ventura County General Plan includes an Area Plan for the Piru Area of Interest, which was amended in 1992. This Area Plan serves as the land use plan for the Piru area, a portion of which is in the CLWA service area. In the near future, a City of Santa Clarita/Los Angeles County Valleywide General Plan for the entire Santa Clarita Valley will be prepared by the City and the County of Los Angeles for lands within their jurisdictions.

In addition to the General Plans, the following Specific Plans have been developed for areas within the CLWA service area:

- Newhall Ranch Specific Plan
- Northlake Specific Plan
- Canyon Park Specific Plan (now Fairbanks Ranch)
- Porta Bella Specific Plan
- North Valencia II Specific Plans
- Stevenson Ranch Specific Plans (Community Contracts)

Specific plans provide detailed land use information for a certain area.

3.2 Existing and Projected Land Uses

The Santa Clarita Valley includes a variety of residential, commercial, industrial, institutional, agricultural, and open space uses. A large portion of the valley is not suitable for development due to steep terrain, flooding potential or federal jurisdiction (Angeles National Forest). However, rapid residential, commercial, and industrial development of portions of the valley floor and canyons has occurred due to growth influences from the Los Angeles metropolitan area

and the presence of three major highways (U.S. Interstate 5/the Golden State Freeway, State Highway 14/the Antelope Valley Freeway, and State Highway 126).

In 1995, the Los Angeles County Department of Regional Planning (LACDRP) digitized the projected land use within the CLWA service area using a geographic information system (GIS) and prepared a series of reports and maps for CLWA. The land use planning data was incorporated into the land parcel database maintained for CLWA. Table 3-1 summarizes the future acreage of each land use type, as contained in the database. This table represents the expected ultimate distribution of land use as defined in the General Plans.

There are a number of development projects underway and seeking approval in the Santa Clarita Valley. Two significant land use types that could be developed in the future, assuming adoption of the necessary General Plan amendments or Specific Plans, are the nearly 40,000 acres designated Hillside Management in Los Angeles County and almost 8,500 acres of agriculture and open space lands in the Ventura County portion of the CLWA service area.

TABLE 3-1
SUMMARY OF CURRENT DESIGNATED LAND USE

Land Use Type	Plan Code	Number of Parcels	Acreage[a]
Commercial	C	2,090	3,130
Hillside Management	HM	4,845	39,674
Industrial	M	1,503	6,167
Municipal	MU	10	136
Non-Urban Residential (0.5 DU/Ac)	N1	3,735	7,622
Non-Urban Residential (1.0 DU/Ac)	N2	369	3,021
National Forest	NF	155	9,090

Total		60,672	118,508

Source: Montgomery-Watson, 1998.
Notes:
(a) Acreage excludes streets and roads for developed areas.
(b) Includes areas in Ventura County, which are currently designated as Agriculture (<1 dwelling unit per 40 acres) and Open Space (<1 dwelling unit per 80 acres). Much of this land is currently used for agriculture.

Section 4: Existing and Projected Potable Water Supply and Demand

In order to evaluate the need for recycled water, potable water supplies and demand projections are briefly summarized. This section describes the existing and future potable water supplies, demands, and facilities within the CLWA service area.

4.1 Existing Water Supply, Demand, and Facilities

4.1.1 Water Supply

Water demands in the Santa Clarita Valley are currently met by two sources: SWP and local groundwater supplies. According to the Upper Santa Clarita Valley Water Committee, the total available water supply for the CLWA service area, including SWP water, groundwater, and recycled water sources, is approximately 96,000 to 151,900 AF/yr.[1] CLWA purchases SWP water and wholesales it to three domestic water purveyors: Los Angeles County Waterworks District (LACWD) No. 35, the Newhall County Water District (NCWD), and the Valencia Water Company (VWC). CLWA acquired the Santa Clarita Water Company in 1999; these areas are now served by the CLWA's Santa Clarita Water Division (SCWD). The approximate boundaries of the water purveyors are shown on Figure 4-1. The three retail purveyors plus CLWA comprise the Upper Santa Clarita Valley Water Committee.

4.1.1.1 Imported Water

The SWP is managed by the California Department of Water Resources (DWR). CLWA is one of 29 agencies holding long-term contracts with the State of California for SWP water. SWP water originates from rainfall and snowmelt in northern and central California. Runoff is stored in Lake Oroville, then released down the Feather River to the Sacramento River and the Sacramento-San Joaquin Delta. Water is diverted into the Clifton Court Forebay, then pumped into the 444-mile long California Aqueduct. Prior to delivery to CLWA, SWP supplies are stored in Castaic Lake at the end of the West Branch of the California Aqueduct. In 1999, CLWA purchased an additional 41,000 AF/yr from the SWP, bringing its total entitlement to 95,200 AF/yr for M&I uses.

4.1.1.2 Groundwater

In addition to imported water, local groundwater supplies have been developed by domestic water purveyors and by agricultural water users. Two freshwater bearing aquifers, the Alluvial and Saugus aquifers, underlie CLWA's boundaries and form the Eastern Groundwater Basin of the Santa Clara River Valley Basin.

The Alluvial aquifer lies above the Saugus aquifer and is comprised of the alluvial sediments along the river and its major tributaries. The maximum thickness of the alluvium is about 200 feet. A large number of wells penetrate this upper aquifer and historically, most water extracted from the groundwater basin has been from the Alluvial aquifer. The perennial yield of the aquifer is considered to be 31,600 to 32,600 AF/yr, a portion of which is used for agricultural

uses. As agricultural land is developed for urban use, an increasing portion of this yield becomes available for M&I use. There is no evidence of any historic or recent trend toward permanent water level or storage decline. Additionally, historic operating results indicate that the aquifer is in good operating condition and can support pumpage above the annual perennial yield of 32,600 AF for one or more years without adverse effects, such as a long-term water level decline or degradation of groundwater quality.

The Saugus aquifer has an estimated storage capacity of 1.4 million AF of usable groundwater. A determination of the annual perennial yield has not been made due to the limited information available. Historically, few wells penetrated the Saugus aquifer. However, as water demands in the Santa Clarita Valley have increased, more wells have been drilled into the aquifer. Presently, about one-third of the supply in the Saugus aquifer has been tapped. Pumpage has averaged about 7,400 AF/yr since 1980. Agricultural use of the Saugus aquifer is considered to be less than 100 AF/yr. The anticipated annual aquifer recharge ranges from a minimum of 11,000 AF/yr in dry years to a minimum of 22,000 AF/yr in wet years. Groundwater levels in the aquifer have remained essentially constant over the last 35 to 40 years. The Saugus aquifer is capable of producing on the order of 40,000 AF/yr for short-term periods.

4.1.2 Water Demand

The three purveyors that purchase imported water from CLWA generally do not serve agricultural water users. Therefore, only M&I demands are included in the total demands for CLWA. In 2001, the existing water demand from all purveyors was 60,678 AF/yr.[2] Peak water demands occur from May through October.

4.1.3 Facilities

Currently, CLWA treats the imported water stored in Castaic Lake at either the Earl Schmidt Filtration Plant or the Rio Vista Water Treatment Plant and delivers it to the water purveyors through a transmission system. CLWA has a capacity to treat 58 million gallons per day (mgd). The main transmission line, the Castaic Conduit, is located east of the Golden State Freeway, generally paralleling the Freeway and Magic Mountain Parkway from Castaic Lake to a point just north and west of Bouquet Junction where two laterals begin. The Honby Lateral roughly follows the north side of the Santa Clara River to the east, where it crosses to the south to serve Saugus. Headed in a southerly direction, the Newhall Lateral parallels San Fernando Road to serve Newhall and Valencia. The conduit system is shown on Figure 4-2. At the present time, CLWA delivers water to the purveyors through 11 turnouts, including those to its SCWD.

4.2 Projected Water Supply, Demand, and Facilities

4.2.1 Water Supply

CLWA's future water supply will continue to come from two main sources: the SWP and groundwater. CLWA is pursuing an additional 20,000 AF/yr in addition to the current entitlement of 95,200 AF/yr to bring the total entitlement to 115,200 AF/yr. When rainfall and snowmelt provide an adequate amount of water, CLWA can obtain water from SWP up to their full entitlement. However, during dry years, there may not be enough water to provide CLWA and other SWP contractors with their full water delivery requests. Under existing water supply and

Figure 4–2

K/J FILE: X:\DWG\014642\FIGURE4-2.DWG REV. DATE: 5/14/2002

demand conditions, CLWA is expected to receive approximately 37,900 AF per calendar year, approximately 10 percent of the time, and, if CLWA requested 100 percent of the entitlement, it would receive approximately 56,800 AF per calendar year approximately 50 percent of the time.

CLWA has completed an Integrated Water Resources Plan (IWRP) that addresses programs for enhancing water supply reliability during such occurrences. A $300 million capital improvement program has been established to provide facilities and additional water supplies needed to firm up imported water supplies during times of drought. Planned supplies include new wells in the Saugus Formation, stormwater, water banking, water transfers, and desalination. Projected water supplies are summarized in Table 4-1.

The sources of groundwater available to users within the CLWA service area will continue to be the alluvial and Saugus aquifers. From the alluvial aquifer, the safe yield is anticipated to be 32,500 AF/yr, a portion of which will be used for agricultural purposes and, therefore, is not available for M&I use. The Saugus aquifer production is anticipated to be 21,000 to 22,000 AF/yr, of which 20,000 AF/yr is assumed to be allocated for use by M&I users within the CLWA service area and 2,000 AF/yr is utilized by other water users.

TABLE 4-1
PROJECTED WATER SUPPLIES IN THE CLWA SERVICE AREA

	Supply (AF/yr)	
Source	**Average Year**	**Dry Year**
Alluvial Basin	30,000 - 40,000	30,000 - 35,000
Saugus Formation	7,500 - 15,000	11,000 - 15,000
Saugus New Wells[a]	–	10,000 - 20,000
Stormwater Runoff[a]	–	–
Recycled Water[a]	1,700 - 17,000	1,700 - 17,000
SWP Supplies	56,800 - 95,200	37,900 - 75,800
Groundwater Bank[a]	–	105,000
Water Transfer[a]	5,500 - 9,200	3,700 - 7,300
Desalination[a]	2,000 - 5,000	2,000 - 5,000
Total	103,200 - 181,400	201,100 - 279,000

Source: CLWA, "Urban Water Management Plan," 2000.
Note: (a) Planned programs for future implementation.

4.2.2 Water Demand

In preparing the 2000 Urban Water Management Plan, several methods of projecting future water demands were examined, including those based on population projections, historic connection data, and econometric models. Table 4-2 summarizes the projected water demands for the CLWA service area. It is anticipated that these projected demands can be met using the water supplies described above, in both wet and dry years.

TABLE 4-2
PROJECTED NORMAL/AVERAGE YEAR WATER USAGE

Land Use	Water Demand (AF/yr)			
	2005	2010	2015	2020
Low-Density Residential	32,500	35,400	39,300	41,000
Medium to High Density Residential	18,200	24,400	32,300	42,100
Commercial	3,100	3,500	4,000	4,500
Industrial	5,100	5,700	6,400	7,100
Recreational	3,600	3,800	4,200	4,500
Institutional	3,100	3,400	3,600	3,900
Miscellaneous Urban Water Use	1,000	1,500	2,100	2,900
Irrigated Agricultural	15,100	12,400	9,800	7,100
Increased Conservation Savings	6,600	7,700	9,100	10,600
Total Projected Water Use	75,100	82,400	91,600	102,500

Section 5: Regulatory Requirements

Production, discharge, distribution, and use of recycled water are subject to federal, state, and local regulations, the primary objectives of which are to protect public health. There are additional regulations that are relevant to oil field produced water, use of impaired waters, such as treated perchlorate-contaminated groundwater, and ASR. This section describes the regulatory requirements and their administration.

5.1 Federal Requirements

Two federal acts regulate the discharge and use of recycled water or wastewater: the Clean Water Act and the Safe Drinking Water Act.

5.1.1 Clean Water Act

Federal requirements relevant to the discharge of recycled water, or wastewater, and any other liquid wastes to "navigable waters" are contained in the 1972 amendments to the Federal Water Pollution Control Act of 1956, commonly known as the federal Clean Water Act (CWA) (Public Law 92-500). The CWA created the U.S. Environmental Protection Agency (USEPA) and established the National Pollutant Discharge Elimination System (NPDES), a permit system for discharge of contaminants to navigable waters. NPDES requires that all municipal and industrial dischargers of liquid wastes apply for and obtain a permit prior to initiating discharge.

5.1.2 Safe Drinking Water Act

Federal requirements relevant to the use of recycled water for groundwater recharge are contained in the 1986 amendments to the Safe Drinking Water Act (SDWA) of 1974 (Public Law 93-523). The SDWA focuses on regulation of drinking water and control of public health risks by establishing and enforcing maximum contaminant levels (MCLs) for various compounds in drinking water. The 1986 amendments also established requirements for protection of groundwater supplies through wellhead protection programs and regulation of underground injection of wastes.

5.1.3 Administration

In the State of California, the administration and enforcement of the NPDES and SDWA programs have been delegated to the state.

5.2 State Requirements

State requirements for production, discharge, distribution, and use of recycled water are contained in the California Water Code, Division 7-Water Quality, Sections 1300 through 13999.16 (Water Code); the California Administrative Code, Title 22-Social Security, Division 4-Environmental Health, Chapter 3-Reclamation Criteria, Sections 60301 through 60475 (Title 22); and the California Administrative Code, Title 17-Public Health, Chapter 5, Subchapter 1, Group 4-Drinking Water Supplies, Sections 7583 through 7630 (Title 17). In addition, guidelines for production, distribution, and use of recycled water have been prepared or endorsed by state agencies administering the recycled water regulations.

5.2.1 Water Code

The Water Code contains requirements for the production, discharge, and use of recycled water. The Porter-Cologne Water Quality Control Act (Division 7 of the California Water Code), which was promulgated in 1969, established the State Water Resources Control Board (SWRCB) as the state agency with primary responsibility for the coordination and control of water quality, water pollution, and water rights (Division 7, Chapter 1).

Nine Regional Water Quality Control Boards (RWQCB) were established to represent the SWRCB regionally and carry out the enforcement of water quality and pollution control measures (Division 7, Chapter 4). In addition, each RWQCB was required to formulate and adopt water quality control plans and establish requirements for waste discharge to waters of the state. In 1972, Chapter 5.5 was added to Division 7 to provide the RWQCBs with the authority to carry out the provisions of the federal CWA. The Los Angeles RWQCB has jurisdiction over the Santa Clarita Valley.

Division 7, Chapter 7-Water Reclamation, was included in the Porter-Cologne Water Quality Control Act in 1969. Subsequent amendments required DHS to establish water reclamation criteria, gave the RWQCB the responsibility of prescribing specific water reclamation requirements for water which is used or proposed to be used as recycled water, provided for the regulation of injection of waste into the ground, and required the use of recycled water, if available, rather than potable water for irrigation of greenbelt areas.

In addition to Division 7, Chapter 7, Sections 1210 through 1212 of the Water Code, added in 1980, focus on the ownership of treated wastewater and require that the owner of a wastewater treatment plant obtain approval from the SWRCB prior to making any change in the point of discharge, place of use, or purpose of use of treated wastewater.

5.2.2 Title 22

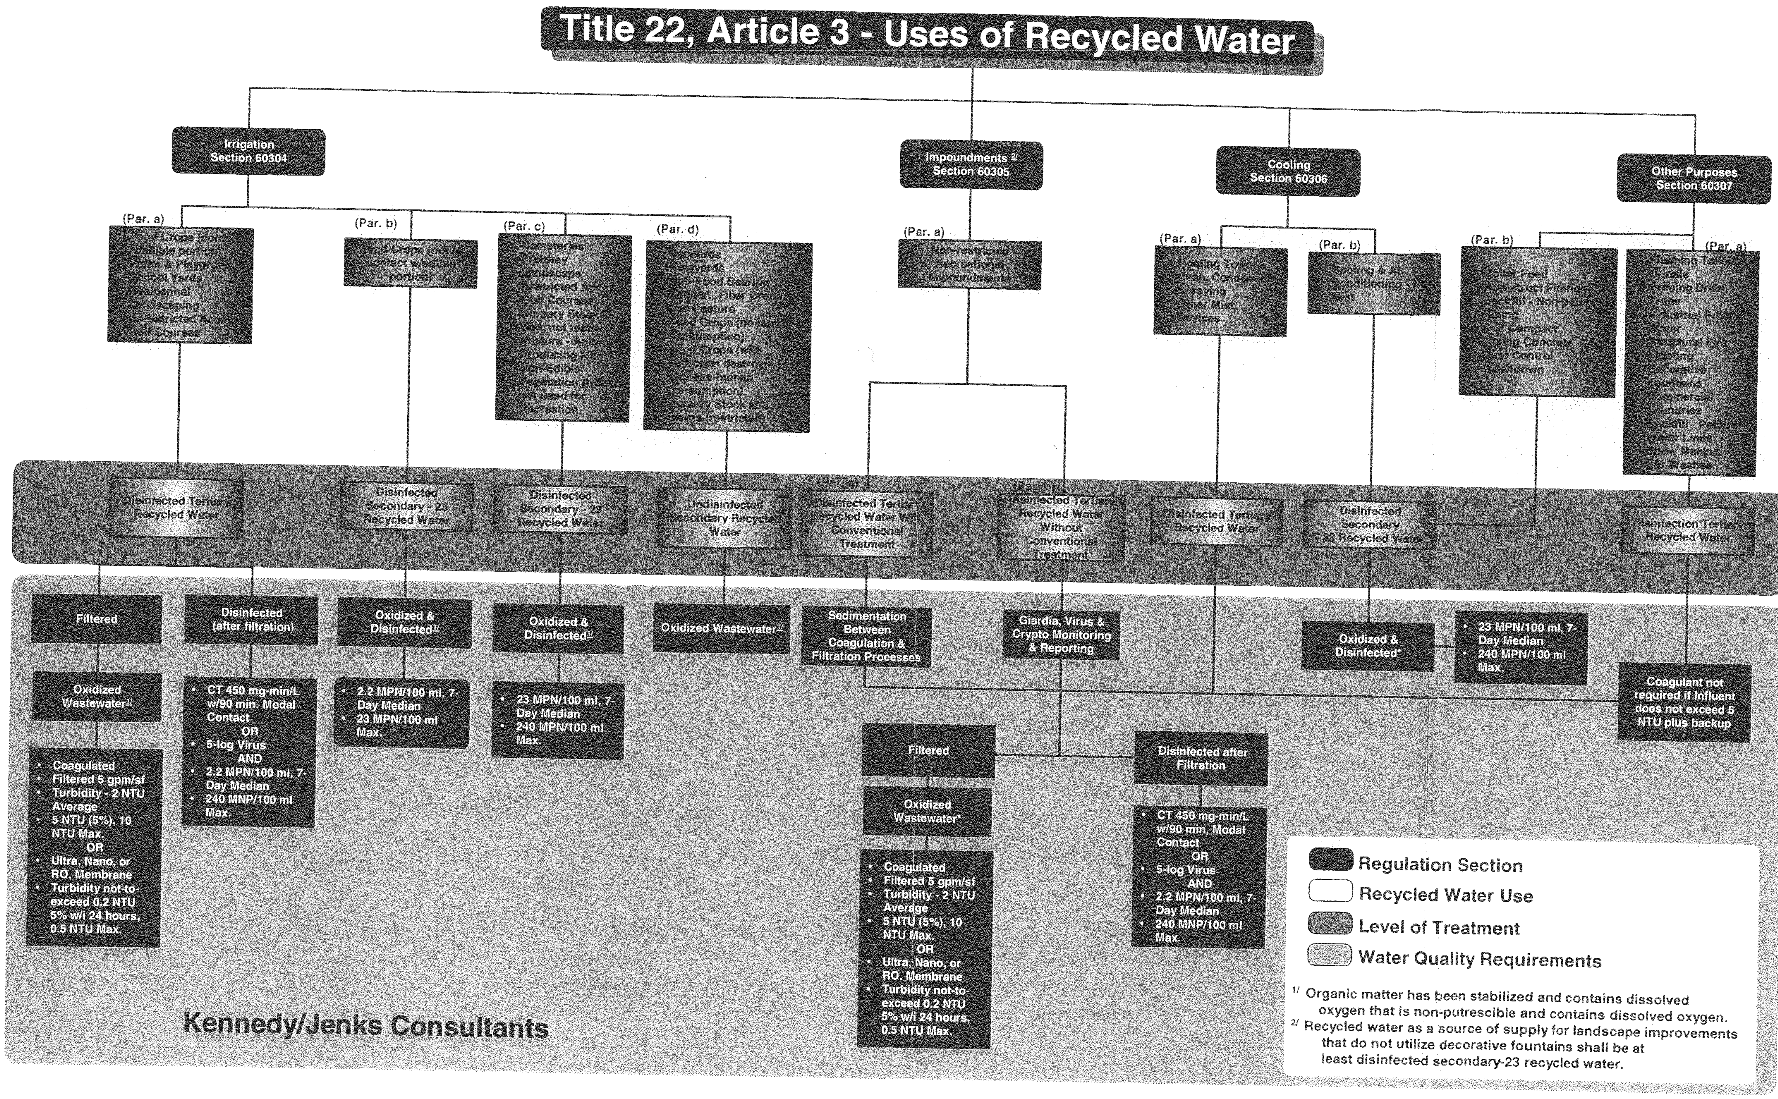
In 1975, Title 22 was prepared by DHS in accordance with the requirements of Division 7, Chapter 7 of the Water Code. In 1978, Title 22 was revised to conform with the 1977 amendment to the federal CWA. The requirements of Title 22, as revised in 1978, 1990, and 2001, regulate production and use of recycled water in California. Title 22 requirements are summarized in Figure 5-1.

Title 22 establishes the quality and/or treatment processes required for an effluent to be used for a specific non-potable application. The following categories of recycled water are identified:

- Disinfected tertiary recycled water
- Disinfected secondary-2.2 recycled water[3]
- Disinfected secondary-23 recycled water[4]
- Undisinfected secondary recycled water
- Disinfected tertiary recycled water with conventional treatment
- Disinfected tertiary recycled water without conventional treatment

---

[3] The 2.2 refers to the coliform count requirement for the water – 2.2 MPN/100 mL.
[4] The 23 refers to the coliform count requirement for the water – 23 MPN/100 mL.



Kennedy/Jenks Consultants

Castaic Lake Water Agency
Recycled Water Master Plan

Understanding Recycled Water Regulations

May 2002
K/J 014642.00

Figure 5-1

In addition to recycled water uses and treatment requirements, Title 22 addresses sampling and analysis requirements at the treatment plant, preparation of an engineering report prior to production or use of recycled water, general treatment design requirements, reliability requirements, and alternative methods of treatment.

A draft regulation issued 23 April 2001 specifically addresses Groundwater Recharge Reuse. The regulations address requirements for the engineering report and monitoring and reporting for projects that use recycled water for groundwater recharge.

5.2.3 Title 17

The focus of Title 17 is protection of drinking (potable) water supplies through control of cross-connections with potential contaminants, including non-potable water supplies such as recycled water. Title 17, Group 4, Article 2 - Protection of Water System, Table 1, specifies the minimum backflow protection required on the potable water system for situations in which there is potential for contamination to the potable water supply.

Recycled water is addressed as follows:

- An air-gap separation is required on "Premises where the public water system is used to supplement the recycled water supply."
- A reduced pressure principle backflow prevention device is required on "Premises where recycled water is used...and there is no interconnection with the potable water system."
- A double-check valve assembly may be used for "Residences using recycled water for landscape irrigation as part of an approved dual plumbed use area established pursuant to sections 60313 through 60316 unless the recycled water supplier obtains approval for the local public water supplier, or [DHS] if the water supplier is also the supplier of the recycled water, to utilize an alternative backflow prevention plan that includes an annual inspection and annual shutdown test of the recycled water and potable water systems pursuant to subsection 60316(a)."

5.2.4 Guidelines

To assist in compliance with Title 22, DHS has prepared a number of guidelines for production, distribution, and use of recycled water. Additionally, DHS recommends use of guidelines prepared by the California-Nevada Section of the American Water Works Association (AWWA). These guidelines are summarized below.

<u>Guideline for the Preparation of an Engineering Report on the Production, Distribution, and Use of Recycled Water.</u> According to Title 22, prior to implementation of a water reclamation project (production, distribution, or use) an engineering report must be prepared and submitted to DHS. This guideline, prepared by DHS and dated March 2001, specifies the contents of an engineering report. The report should describe the production process, including the treated (effluent) water quality, the raw water quality, the treatment process, the plant reliability features the supplemental water supply, the monitoring program, and a contingency plan to prevent distribution of inadequately treated water. The report should include maps of the distribution system and describe how the system will comply with DHS and AWWA guidelines and Title 17. The report should include maps of proposed use areas and should describe the use areas, the

types of uses proposed, the people responsible for supervising the uses, the design of the user systems, and the proposed user inspection and monitoring programs.

Manual of Cross Connection Control/Procedures and Practices. This manual, dated July 1981, focuses on establishing a cross-connection control program to protect the public against backflow and back-siphonage of contamination. Main elements of the manual include areas where protection is required; causes of backflow; approved backflow preventers; procedures, installation, and certification of backflow preventers; and water shutoff procedures (for conditions which pose a hazard to the potable water supply).

Guidelines for the Distribution of Nonpotable Water. These guidelines were prepared by the California-Nevada Section of AWWA in 1992. The purpose of these guidelines is to provide guidance for planning, designing, constructing, and operating non-potable water systems, including recycled water systems. Distribution lines, storage and supply, pumping, on-site (user) applications, and system management are discussed. DHS guidelines reference these guidelines.

Guidelines for the On-Site Retrofit of Facilities Using Disinfected Tertiary Recycled Water. The California-Nevada Section of AWWA prepared these guidelines in 1997 to provide guidance on modifying existing on-site facilities for conversion to use of recycled water, including recommendations for signage, backflow prevention, and separation standards, for landscape irrigation, agricultural irrigation, industrial uses, and impoundments.

5.2.5 Oil Field Produced Water-Related Regulations

In California, there are no regulations addressing the use of treated oil field produced water for non-potable purposes. However, certain aspects of the reclamation standards and design criteria for treatment of domestic wastewater for a direct beneficial reuse or a controlled use that would not otherwise occur are applicable. For example, the water must meet the Basin Plan standards.

5.2.6 Treated Perchlorate-Contaminated Groundwater-Related Regulations

In California, there are no regulations addressing the use of treated perchlorate-contaminated groundwater for non-potable purposes. However, certain aspects of the reclamation standards and design criteria for treatment of domestic wastewater for a direct beneficial reuse or a controlled use that would not otherwise occur are applicable. For example, the water must meet the Basin Plan standards and applicable NPDES or Waste Discharge Requirements (WDR).

5.2.7 Administration

In the State of California, reclamation requirements are administered by the SWRCB, the individual RWQCBs, and DHS. The direct involvement of each agency in water recycled is summarized below:

SWRCB

1. Issue loans in accordance with the Water Code.

2. Approve petitions for the change in place and purpose of use of treated wastewater in accordance with the Water Code.

RWQCB

1. Prepare or revise reclamation requirements in accordance with the Water Code.
2. Review and approve engineering report required under Title 22.
3. Review and approve recharge projects using recycled water in accordance with the Water Code.

DHS

1. Review and approve engineering report as requested by RWQCB.
2. Review and approve final plans for cross connection control and pipeline separations in accordance with Title 17, and inspect distribution system prior to operation.
3. In conjunction with local health agencies, review and approve final on-site (user) system plans for cross connection control in accordance with Title 17, and inspect system prior to operation.

The DHS has delegated a portion of its administrative duties to local health agencies and becomes more involved at the request of the local health agencies.

5.3 Local Requirements

Local requirements focus on the distribution and use of recycled water and, primarily, the onsite (user) systems, with emphasis on cross-connection control. State regulations and guidelines discussed above are the governing requirements. The Los Angeles County Department of Health Services (LACDHS) Cross-Connection and Water Pollution Control Program establishes more specific requirements for the separation and construction of potable and recycled water lines, guidelines for on-site (user) systems, and identification of recycled water facilities.

The local requirements are also administered by LACDHS as follows:

1. Review as-built drawings of user's potable water system.
2. Perform an onsite survey of the user's water system.
3. Guide users in methods of identifying potable and recycled water systems.
4. Review and approve design drawings of user's recycled water systems.
5. Inspect user's potable and recycled water systems following construction.

Section 6: Recycled Water Sources

The extent of the recycled water system is dependent on the amount of water available, as well as the quality of this water. This section presents an overview of sources of recycled water, flow, and quality in the Santa Clarita Valley. It also covers other potential sources of water for the recycled water system, including treated perchlorate-contaminated groundwater and treated oil field produced water.

6.1 Sources of Recycled Wastewater

now only 1 District

LACSD provides wastewater collection, treatment, and disposal services to residents of two sanitation districts in the Santa Clarita Valley: District Nos. 26 and 32. District No. 26 serves the eastern portion of the valley, and District No. 32 serves the western portion. The majority of the two districts' service areas lie within the City of Santa Clarita.

6.1.1 Existing and Planned Wastewater Treatment Facilities

6.1.1.1 Existing Facilities

LACSD operates two wastewater treatment facilities in the Santa Clarita Valley: Saugus and Valencia WRPs. The two treatment facilities operated independently until 1980, at which time the two plants were linked by a bypass interceptor. The interceptor was installed to transfer a portion of flows received at the Saugus WRP to the Valencia WRP. In order to improve operating efficiencies and because a shortage of space at the Saugus WRP limits future expansion of wastewater facilities in District No. 26, a joint powers agreement was enacted in 1984, creating the Santa Clarita Valley Joint Sewerage System. Through use of wastewater and sludge connecting lines, future expansions of treatment works, including sludge handling and disposal operations, will be provided at the larger Valencia WRP.

The primary sources of wastewater to the Saugus and Valencia WRPs are domestic. Both plants are tertiary treatment facilities and produce high quality effluent. Currently, the effluent from the two WRPs discharges to the Santa Clara River. The Saugus WRP effluent outfall is located approximately 400 feet downstream (west) of Bouquet Canyon Road. Effluent from the Valencia WRP is discharged to the Santa Clara River at a point approximately 2,000 feet downstream (west) of The Old Road Bridge.

Together, the Valencia and Saugus WRPs have a design capacity of 20 mgd (22,410 AF/yr). In calendar year 2001, they produced an average of 16.89 mgd. However, none of the effluent was used as recycled water during this period. Monthly flow data for both WRPs is shown in Table 6-1. During fiscal year 1999-2000 the WRPs produced 16.25 mgd (18,262 AF/yr) of recycled water available for reuse. As the 2001 data was not available at the time the recycled water analysis was initiated, the 16.25 mgd flow was used for this Recycled Water Master Plan.

TABLE 6-1
MONTHLY EFFLUENT FLOW FROM VALENCIA AND SAUGUS WRPs - CALENDAR YEAR 2001

Month	Saugus WRP Flow (mgd)	Valencia WRP (mgd)	Total Flow (mgd)
January	6.22	10.13	16.35
February	6.18	10.65	16.83
March	6.01	10.97	16.98
April	5.54	11.00	16.54

October	5.54	11.63	17.17
November	6.01	11.44	17.45
December	5.89	11.17	17.06
Annual Average	5.67	11.22	16.89

Source: LACSD.

Located within District No. 26, the Saugus WRP is southeast of the intersection of Bouquet Canyon Road and Soledad Canyon Road and was completed in 1962. Two subsequent expansions and flow equalization facilities brought its current design capacity to 6.5 mgd. The treatment process was brought up to a tertiary level with the addition of dual-media pressure filters in 1987. However, no future expansions are possible due to space limitations at the site. In 2001, the Saugus WRP produced an average effluent flow of 5.67 mgd (6,350 AF/yr). Use of recycled water from this facility is permitted under RWQCB Order No. 87-49; however, LACSD staff has expressed concern about diverting these discharges due to potential impacts to downstream habitat. The habitat implications of effluent diversion are discussed in greater detail in Section 7. Until more detailed habitat investigations are conducted, it is assumed that only recycled water from the Valencia WRP will be used.

The Valencia WRP is located within District No. 32 and is on The Old Road near Magic Mountain Amusement Park, as shown in Figure 6-1. A schematic of the Valencia WRP's processes is presented on Figure 6-2. The Valencia WRP was completed in 1967. Following two subsequent expansions, construction of a 4.4 million gallon flow equalization tank in February 1995 and the Stage 4 expansion completed in June 1996, it now has a design capacity of 13.5 mgd. In 2000, the Valencia WRP produced an average effluent flow of 11.22 mgd (12,600 AF/yr). Use of recycled water from the Valencia WRP is permitted under RWQCB Order No. 87-48. On 24 July 1996, CLWA executed an agreement with LACSD to purchase up to 1,600 AF/yr of recycled water from the Valencia WRP. CLWA has been constructing the facilities to utilize this supply and expects to initiate deliveries in 2002. Recycled water from Valencia WRP has been used in the past by the City of Santa Clarita for landscape irrigation and by Pacific Pipeline and Oberg Construction for construction applications. These deliveries were made via tanker truck. In April 2000, a contract was signed with TransCoast Financial for use of up to 20,000 gpd for dust control at a nearby composting facility. The recycled water will be transported via tanker truck.

6.1.1.2 Planned Improvements and Expansions

To accommodate anticipated growth in the Santa Clarita Valley and to ensure compliance with discharge requirements from the RWQCB, LACSD plans to expand the Valencia WRP. The ultimate capacity of the WRP is planned to be 22 mgd, bringing the ultimate total for both WRPs to 27.6 mgd. No expansion is planned at the Saugus WRP. Construction is expected to occur in 3 mgd increments. Table 6-2 and Figure 6-3 present the projected expansion and flow scenario for the combined Valencia and Saugus WRP planning area.

6.1.1.3 Newhall Ranch Water Reclamation Plant

A third reclamation plant for the Santa Clarita Valley is proposed as part of the Newhall Ranch project. This proposed facility would be located near the western edge of the development project along the south side of State Route 126. The plant will be constructed in stages, with an ultimate capacity of 7.7 mgd. Effluent from the proposed water reclamation plant will be used to meet non-potable water demand within the development area. According to the Newhall Ranch Draft Additional Analyses, this plant is projected to produce 5,344 AF/yr on average. During the dry months, all of the recycled water will be used for non-potable uses within Newhall Ranch, supplemented by additional recycled water from CLWA. During the wet winter months when demands are low, the Newhall Ranch WRP will have approximately 286 AF/yr excess recycled water. In order for the WRP to be non-discharging, this recycled water will be transferred into the CLWA recycled water system for use and/or storage.

6.1.2 Water Quality

6.1.2.1 Recycled Water Quality Requirements

Effluent quality from the Valencia and Saugus WRPs is regulated by the RWQCB. Discharge permits specifying the wastewater quality requirements for effluent discharged to the Santa Clara River have been issued for each plant. Each plant also has a reclamation permit specifying wastewater quality requirements for recycling of effluent; however, as discussed previously, small quantities of recycled water have only been used intermittently and have been transported via tanker truck.

Depending on the place and purpose of the recycled water use, the necessary treatment processes and the maximum allowable concentrations vary. These variations are addressed in the reclamation permits. Recycled water uses are limited to those identified in the permits. The

Figure 6-3

G:\PROJECTS\2001\014642.00\report\Figure 6-3.ppt permits specify that recycled water used as a source of supply in a non-restricted recreational impoundment (use subject to the most stringent requirements) must be adequately disinfected, oxidized, coagulated, clarified, filtered wastewater.

The wastewater quality limitations specified in the reclamation permits conform to the reclamation criteria contained in the California Administrative Code, DHS, Title 22, Division 4, Chapter 3, "Reclamation Criteria." In addition, because the groundwater in the Santa Clarita Valley is beneficially used for domestic supply and other purposes, the reclamation permits stipulate that recycled water cannot contain trace constituents and other substances in excess of the limits set forth in the current edition of the State Drinking Water Standards (California Administrative Code, DHS, Title 22, Division 4, Chapter 15, "Domestic Water Quality and Monitoring.") The maximum constituent concentration limitations for recycled water are listed in Table 6-3.

The reach of the Santa Clara River to which the Valencia WRP discharges (Reach 7) is listed in the 1998 303(d) list of impaired water bodies for ammonia, chloride, and nitrite. The RWQCB has recently issued a draft total maximum daily load (TMDL) of 90 mg/l of chloride for the Valencia and Saugus WRPs. This requirement, if adopted, would require desalination of the effluent prior to discharge or reuse. Potential future limitations on ammonia, nitrate, and nitrite are expected to be met by denitrification.

6.1.2.2 Effluent Quality

The quality of effluent from the Valencia WRP has consistently been in compliance with the recycled water requirements specified in its reclamation permit. Average concentrations of effluent constituents measured during fiscal year 1999-2000 for each plant are listed in Table 6-3. Additionally, the tertiary-treated wastewater is "adequately disinfected, oxidized, coagulated, clarified, filtered wastewater" as specified for use of recycled water in non-restricted recreational impoundment, the use subject to the most stringent requirements in the permits.

The effluent from the WRPs continues to comply with the discharge requirements, as well. During fiscal year 1999-2000, at the Valencia WRP, the $BOD_{5,30}$ measured was approximately 7 mg/l, and suspended solids concentrations averaged <2 mg/l.

μg/l: micrograms per liter

6.2 Perchlorate Contaminated Wells

The Whittaker-Bermite site in Santa Clarita has historically been used for the manufacture of solid rocket propellants, munitions, and fireworks. Improper use or disposal of the chemical compounds and waste products has resulted in soil and groundwater contamination of the site. Preliminary compounds of potential concern for groundwater include ammonium perchlorate, octahydro-1,3,5,7-Tetranitro-1,3,5,7-Tetrazocine (HMX), Hexahydro-1,3,5-Trinitro-1,3,5-Triazine (RDX),and nitrosodimethylamine (NDMA).

on

Production wells in both the alluvium and Saugus aquifers have been sampled to determine whether contamination from the Whittaker-Bermite site has affected them. None of the production wells sampled in the alluvium (Stadium, V-U4, V-T2, V-4, and V-U2) contained detectable concentrations of perchlorate, NDMA, HMX, ~~and~~ RDX. Groundwater samples from nine production wells screened in the Saugus aquifer have been analyzed for the constituents of concern. Perchlorate was detected in groundwater samples from four of the nine Saugus wells sampled (NC-11, Saugus 1, Saugus 2, and V-157), at concentrations ranging from 14 to 45 μg/l. Groundwater samples collected from Saugus production wells NC-11, Saugus 1, Saugus 2, and V-157 were also analyzed for NDMA, HMX, RDX, and volatile organic compounds (VOCs). NDMA, HMX, and RDX were not detected in the groundwater samples. TCE was detected in Saugus 1, Saugus 2, and V-157 at concentrations less than the MCL.[5]

There is currently a remediation effort underway to address the perchlorate contamination. While the Remedial Action Plan has not been prepared, the most likely scenario is that contaminated groundwater will be pumped from four production wells and treated to potable standards at a centralized treatment facility near the wells. The location of the facility and the treatment technologies remain to be determined. The treatment capacity may be as high as 8,700 gpm (13,750 AF/yr). If DHS requires a demonstration period for the facility (approximately 1 to 2 years), the treated water could ~~be~~ beneficially used in the recycled water system. The earliest the facility will be on-line is ~~2003~~.

6.3 Oil Field Produced Water

Oil field produced water is a by-product of oil production generated when oil is pumped out of the reservoir. It is generally of poor water quality and unsuitable for potable, industrial, or irrigation use without treatment. Oil companies are finding that oil production may improve if the oil field produced water is disposed of on the surface rather than through reinjection. However, because of the water quality, reinjection has often been the most cost-effective disposal option.

Treatment processes can produce potable quality water; however, because of the poor initial water quality and the organic constituents, it is often more appropriate for treated oil field produced water to be used for irrigation or industrial purposes to offset potable water demand. Pilot studies performed at the Placerita Oil Field have indicated that even with reverse osmosis (RO) treatment, some organic compounds such as naphthalene, 2-butanone, and ethylbenzene, can be detected in the RO effluent.

The economics of oil production are market-driven and are different from those of drinking water supplies. As oil prices rise or drop, oil fields go into and out of production depending on the

[5] Hargis + Associates Inc., "Field Sampling Plan Technical Memorandum Reconnaissance Groundwater Investigation (Operable Unit 7), Operable Units 2 and 3," 21 April 2000.

costs of production. Therefore, the reliability of oil field produced water should be considered as a long-term, but not a permanent supply.

Studies of the potential reuse of treated oil field produced water from the Placerita Oil Field have indicated that approximately 44,000 barrels per day (1.8 mgd) of treated oil field produced water may be available. For irrigation reuse, the produced water would need to be cooled and treated to remove hardness, silica, total dissolved solids (TDS), boron, ammonia, and total organic carbon (TOC). Water quality for the Placerita Oil Field produced water is summarized in Table 6-4.

TABLE 6-4
PLACERITA OIL FIELD PRODUCED WATER QUALITY

Parameter	Untreated	Treated
TDS	~6,000 mg/l	145 mg/l
Temperature	150-175°F	90°F
Boron	~16 mg/L	1-2 mg/l
Ammonia	9.3 mg/l	2-11 mg/l
Silica	~10 mg/l	<1 mg/l
Hardness	1-5 mg/l	<1 mg/l
TOC	120 mg/l	2 mg/l

6.4 Summary of Available Source Water Flows

As discussed previously, there are four potential sources of water for the non-potable water system. The flows projected to be available are shown in Table 6-5. The sources of non-potable water are presented in Figure 6-4.

TABLE 6-5
SUMMARY OF AVAILABLE SOURCE WATER FLOWS

Source	Current Flow	Projected Flow	Available for Non-Potable Use
Valencia WRP	10.84 mgd	27.6 mgd	19,995 AF/yr
Saugus WRP	5.41 mgd	6.5 mgd	0 AF/yr
LACSD Total	16.25 mgd	34.1 mgd	19,995 AF/yr
Oil Field Produced Water	0 mgd	1.8 mgd	1,980 AF/yr
Treated Perchlorate Contaminated Water[a]	0 mgd	12.5 mgd	11,000 AF/yr
Newhall Ranch WRP	0 mgd	4.78 mgd	5,344 AF/yr
		Total	
		Without Treated Perchlorate Contaminated Water	27,319 AF/yr
		With Perchlorate Contaminated Water	38,319 AF/yr

Note: (a) Treated perchlorate contaminated water will only be available during the DHS demonstration period (1-2 years) for the planned treatment facility.

6.5 Water Quality Requirements for Irrigation

Landscape irrigation appears to be the primary potential use for recycled water. Table 6-6 lists guidelines for irrigation water quality standards and compares the quality of the recycled water available from the Valencia WRP, treated perchlorate-contaminated groundwater, and treated oil field produced water to the standards. Table 6-6 also presents the recommended maximum concentrations in irrigation water and compares the quality of the potential recycled water sources to the recommendations.

From the guidelines, sodium and chloride levels for unblended recycled water are relatively high and may prove toxic to some plants after repeated sprinkler irrigation. If sensitive plants are to be irrigated with recycled water, application of the water by a drip irrigation system or surface system should be considered. In addition, ammonia and nitrate concentrations and boron concentrations fall into the "increasing problems" range and could prove toxic to sensitive plants over a period of time. Salinity of the recycled water also falls into the "increasing problems" range; however, plants vary widely in tolerance to salinity. Provision of adequate soil drainage will help to alleviate any potential problems due to salinity.

Table 6-6 does not list the adjusted sodium adsorption ratios (SAR) of the water sources. The adjusted SARs are related to carbonate and bicarbonate concentrations were not available. However, the unadjusted SAR of the recycled water is below 10, which classifies it as low-sodium water. In addition, the residual sodium bicarbonate levels of the recycled water are relatively low. Because the SAR and residual bicarbonate levels are low, the potential for reducing soil drainage is low. The nutrient composition (nitrogen and phosphorus) of the effluent appears beneficial for irrigation and may result in a reduction in fertilizer use.

Table 6-7 focuses on trace element water quality from Valencia WRP, which would be the largest source of water for the recycled water system. As shown in Table 6-7, the recycled water from Valencia WRP does not exceed any of the recommended values for trace elements in irrigation water. Inadequate data are available on trace element concentrations in oil field produced water and treated perchlorate-contaminated groundwater.

TABLE 6-6
COMPARISON OF AVAILABLE WATER QUALITY TO IRRIGATION QUALITY STANDARD GUIDELINES

Potential Irrigation Problem	Parameter	Units	Degree of Restriction on Use: None	Degree of Restriction on Use: Slight to Moderate	Degree of Restriction on Use: Severe	Recycled Water from Valencia WRP	Treated Oil Field Produced Water	Treated Perchlorate Contaminated Groundwater[a]

TABLE 6-7
RECOMMENDED MAXIMUM CONCENTRATIONS OF TRACE ELEMENTS IN IRRIGATION WATER

Element	Recommended Maximum Concentration (mg/l)[a]	Valencia WRP	Remarks
Aluminum (Al)	5.0	NA	Can cause non-productivity in acid (pH < 5.5), but more alkaline soils at pH > 7.0 will precipitate the ion and eliminate any toxicity.
Arsenic (As)	0.10	<0.0010	Toxicity to plants varies widely, ranging from 12 mg/l for Sudan grass to less than 0.05 mg/l for rice.
Beryllium (Be)	0.10	<0.0025	Toxicity to plants varies widely, ranging from 5 mg/l for kale to 0.5 mg/l for bush beans.
Cadmium (Cd)	0.01	<0.002	Toxic to beans, beets, and turnips at concentrations as low as 0.1 mg/l in nutrient solutions. Conservative limits recommended to its potential for accumulation in plants and soils to concentrations that may be harmful to humans.
Cobalt (Co)	0.05	NA	Toxic to tomato plants at 0.1 mg/l in nutrient solution. Tends to be inactivated by neutral and alkaline soils.
Chromium (Cr)	0.10	<0.01	Not generally recognized as an essential growth element. Conservative limits recommended due to lack of knowledge on its toxicity to plants.
Copper (Cu)	0.20	<0.01	Toxic to a number of plants at 0.1 to 1.0 mg/l in nutrient solutions.
Fluoride (F)	1.0	0.41	Inactivated by neutral and alkaline soils.
Iron (Fe)	5.0	0.10	Not toxic to plants in aerated soils, but can contribute to soil acidification and loss of availability of essential phosphorus and molybdenum. Overhead sprinkling may result in unsightly deposits on plants, equipment, and buildings.
Lithium (Li)	2.5	NA	Tolerated by most crops to 5 mg/l; mobile in soil. Toxic to citrus at low concentrations (<0.075 mg/l). Acts similarly to boron.
Manganese (Mn)	0.20	0.04	Toxic to a number of crops at a few tenths to a few mg/l, but usually only in acid soils.
Molybdenum (Mo)	0.01	NA	Not toxic to plants at normal concentrations in soil and water. Can be toxic to livestock if forage is grown in soils with high concentrations of available molybdenum.
Nickel (Ni)	0.20	<0.02	Toxic to a number of plants at 0.5 to 1.0 mg/l; reduced toxicity at neutral or alkaline pH.
Lead (Pb)	5.0	0.04	Can inhibit plant cell growth at very high concentrations.

Element	Recommended Maximum Concentration (mg/l)[a]	Valencia WRP	Remarks
Selenium (Se)	0.02	<0.0010	Toxic to plants at concentrations as low as 0.025 mg/l and toxic to livestock if forage is grown in soils with high concentrations of added selenium. An essential element to animals, but in very low concentrations.
Tin (Sn) Titanium (Ti) Tungsten (W)	–	NA	Effectively excluded by plants; specific tolerance unknown.
Vanadium (V)	0.10	NA	Toxic to many plants at relatively low concentrations.
Zinc (Zn)	2.0	0.05	Toxic to many plants at widely varying concentrations; reduce toxicity at pH > 6.0 and in fine textured or organic soils.

Source: CA/NV Section of AWWA, "Guidelines for the On-Site Retrofit of Facilities Using Disinfected Tertiary Recycled Water," 1997.

Note: (a) The maximum concentration is based on a water application rate which is consistent with good irrigation practices (10,000 m^3 per hectare per year). If the water rate greatly exceeds this, the maximum concentration should be adjusted downward accordingly. No adjustment should be made for application rates less than 10,000 m^3 per hectare per year. The values given are for water used on a continuous basis at one site.

Section 7: Potential Recycled Water Constraints

This section provides a brief overview of the constraints on the use of recycled water in the CLWA service area, including environmental considerations and water rights issues.

7.1 Environmental Considerations

Effluent from the Valencia and Saugus WRPs is currently discharged to the Santa Clara River, supplementing ephemeral flows. Because effluent discharges from the WRPs flow through riparian habitat of several endangered species, assessment of the potential impact of a recycling project on the habitat is important.

7.1.1 Hydrology of the Santa Clara River

Beginning in the San Gabriel Mountains east of Santa Clarita, the Santa Clara River flows approximately 84 miles westward to the Pacific Ocean. Surface flow typically occurs during the rainy or snowmelt seasons; however, portions of the river have surface flow year round. Natural "rising water," agricultural runoff, and other miscellaneous flow contribute to the year-round flow.

In the Santa Clarita Valley, the Valencia and Saugus WRPs contribute to the river flow year-round. Typically, there is year-round surface flow in the river from the Valencia WRP to the vicinity of Piru. In summer months, it appears that the effluent from the WRPs comprises a significant portion of the river flow. An analysis was performed to estimate the current effluent contribution from the two WRPs to the total average stream flow on a monthly basis. The analysis was based on 10 years of stream flow data from Stream Gauge F92C-R provided by the County of Los Angeles Department of Public Works and effluent flow data for the Saugus and Valencia WRPs from LACSD. Stream gauge F92C-R is located on the Union Pacific Railroad bridge, which crosses the Santa Clara River and runs adjacent to Interstate 5. Stream gauge F92C-R has been given several names throughout its forty-year existence, including "Santa Clara River at Railroad Bridge" and "Old Road Bridge". Based on the available data, combined effluent flows from both treatment facilities contribute more than 90 percent of the total river flow from July through October. Table 7-1 summarizes this analysis.

7.1.2 Riparian Habitat

The Santa Clara River is one of the few major drainages of the San Gabriel Mountains that remains predominantly unchannelized. It includes freshwater marshes and woodland communities. These habitat types are rapidly disappearing and are important to the local wildlife, as described in numerous biological resource assessments. Such assessments have assisted the Department of Regional Planning, Los Angeles County, in designating Significant Ecological Areas (SEAs) within the county. The original SEA study was completed in 1972, with the second following in 1976. The existing 61 SEAs reflect the findings from the 1976 study. To date, the river plain from the vicinity of the Valencia WRP downstream to the Ventura/Los Angeles County line is designated a SEA by Los Angeles County. However, the increase in population and developed land within the Los Angeles County has created the need to re-evaluate the existing SEA program as part of the next General Plan amendment. The 2001 proposed Santa Clara SEA encompasses the entire Los Angeles County reach of the Santa Clara River, primarily within unincorporated areas of Los Angeles County.

TABLE 7-1
PERCENTAGE OF CURRENT STREAM FLOW AS EFFLUENT

Month	1990-2000 F92C-R Reading (mgd)[a]	2000 Valencia WRP Flow (mgd)	2000 Saugus WRP Flow (mgd)	Natural River Flow (mgd)[b]	Total River Flow (mgd)[c]	Effluent % of Flow
January	110	10.62	5.19	104.81	120.62	13%
February	115	10.74	5.47	109.53	125.74	13%
March	28	10.8	5.27	22.73	38.8	41%
April	18	11.02	5.32	12.68	29.02	56%
May	17	11.21	5.29	11.71	28.21	58%

November	12	11.21	5.58	6.42	23.21	72%
December	24	10.62	6.26	17.74	34.62	49%

Notes:
(a) Average based on 10 years of stream flow data, 1990-2000, from Los Angeles County Department of Public Works Stream Gauge F92C-R.
(b) Stream gauge F92C-R less the upstream Saugus WRP flow.
(c) Stream gauge F92C-R monthly average plus downstream Valencia WRP flow.

7.1.3 Endangered Species

The Santa Clara River supports numerous sensitive biological resources, including habitats and individual species, which have been afforded special recognition by federal, state, or local conservation agencies and organizations as endangered, threatened, rare, or otherwise of concern. Table 7-2 presents the habitats as well as plant and animal species present, or potentially present within the Santa Clara River that have been afforded special recognition as described in the 2001 Draft Biological Resource Assessment of the Proposed Santa Clara River SEA. The species in Table 7-2 have been recorded within the SEA as well as those reasonably expected to occur. The location of each species reflects observations, records in the California Natural Diversity Database, or reported in previous documentation as observed within or in the immediate vicinity of the proposed SEA.

TABLE 7-2
SENSITIVE SPECIES OCCURRING OR POTENTIALLY OCCURRING WITHIN THE PROPOSED SANTA CLARA RIVER SEA

Scientific Name	Common Name	Agency Listing Status[a]	Preferred Habitat	Location
FISH				
Gasterosteus aculeatus williamsoni	unarmored threespine stickleback	FE, SE, SFP	Fresh water rivers and streams in the L.A. basin; low flow areas.	Common in Santa Clara River, Arrastre Creek
Catostomus santaanae	Santa Ana sucker	FE, CSC	Sand, rubble, boulder bottoms; cool, clear water; feed on algae.	Santa Clara River
AMPHIBIANS				
Bufo microscaphus californicus	arroyo southwestern toad	FE, CSC, SP	Washes/streams, sandy banks, grown to willows, cottonwoods or sycamores; riparian habitats of semi-arid areas, small cobbly streambeds.	One individual recorded along the Santa Clara River; San Francisquito Cyn.; Castaic Creek (above dam)
REPTILES				
Clemmys marmorata pallida	southwestern pond turtle	FSC, CSC, SFP	Ponds, marshes, rivers, streams, irrigation ditches.	Ben Cyn.; Vasquez Rocks; one individual in Santa Clara River, Newhall Ranch
Cnemidophorus tigris multiscutatus	coastal western whiptail	FSC	Arid and semi-arid desert to open woodlands, where vegetation is sparse.	Santa Clara River and San Francisquito Creek; Common in SEA
Diadophis punctatus modoestus	San Bernardino ring-neck snake	FSC	Open, relatively rocky areas, within valley-foothill, mixed chaparral, and annual grass habitats.	Placerita Cyn; Santa Clara River
BIRDS				
Ixobrychus exilis hesperis	western least bittern	CSC	Emergent wetlands of cattails and tules.	Santa Clara River
Accipiter cooperi	Cooper's hawk	CSC	Open woodlands especially riparian woodland.	Santa Clara River nesting records; foraging over Newhall Ranch; San Francisquito Creek, common in SEA
Buteo swainsoni	Swainson's hawk	ST	Plains, ranges, open hills, sparse trees.	Occasional along Santa Clara River; Newhall (100 birds in 2000)
Elanus leucurus	white-tailed kite	SFP	Grasslands with scattered trees, near marshes, along hwys.	Nesting in woodlands along Santa Clara River, Live Oak Springs Cyn., Placerita Cyn.; near Pico Cyn.; common locally
Coccyzus americanus occidentalis	western yellow-billed cuckoo	SE	Riverine woodlands, thickets, and farms.	Record from Santa Clara River near Magic Mountain Park (Newhall Ranch; 1974)

Scientific Name	Common Name	Agency Listing Status[a]	Preferred Habitat	Location
Empidonax traillii extimus	southwestern willow flycatcher	FE	Low elevation sites: Riparian woodlands that contain water and low growing willow thickets. High elevation sites: Large, flat, wet meadows that contain patches of willow trees.	One individual observed in mature riparian woodlands of Santa Clara River; nests near Lang, approx. 6 mi. E of Newhall
Lanius ludovicianus	loggerhead shrike	FSC, CSC	Open habitats with scattered shrubs, trees, posts, fences, utility lines, or other perches.	4 pairs near agricultural fields/open chaparral near San Francisquito Creek; near Santa Clara River at County line; common locally in SEA
Vireo bellii pusillus	least Bell's vireo	FE, SE	Perennial and intermittent streams with low, dense riparian scrub and riparian woodland habitats below 2,000 feet elevation; nests primarily in willows and forages in the riparian and occasionally in adjoining upland habitats.	Small population recorded in Santa Clara River riparian woodland and scrub zone along the Ventura-LA county border; Castaic Creek at Santa Clara River
Dendroica petechia brewsteri	yellow warbler	CSC	Riparian woodlands, montane chaparral, and mixed conifer habitats.	Several pairs recorded nesting in Nat'l Forest near Francisquito Creek; occasionally nests along Santa Clara River
Icteria virens	yellow-breasted chat	CSC	Riparian woodlands with a thick understory.	One individual recorded in San Francisquito Creek near Santa Clara River
Piranga rubra	Summer tanager	CSC	Cottonwood-willow woodland and riparian scrub.	Santa Clara River near Lang
MAMMALS				
Antrozous pallidus	pallid bat	CSC	Nests in dry, rocky habitats/caves, crevices in rocks, arid habitats including deserts, chaparral, and scrublands.	Historic records in Santa Clara River watershed, Soledad Cyn., and Castaic Creek; common locally
Neotoma lepida intermedia	San Diego desert woodrat	FSC, CSC	Chaparral, coastal sage scrub, and pinyon-juniper woodland.	Adjacent to Santa Clara River, Newhall Ranch; common in SEA

Note: (a)
FE Federally Listed as Endangered
FSC Federally Special Concern Species
SE State Listed as Endangered
SP State Protected
SFP State Fully Protected
CSC California Special Concern Species

7.1.4 Potential Impact of the Recycled Water System on Instream Flows

Because effluent from the Saugus and Valencia WRPs comprises a majority of the flow in the Santa Clara River during summer months, it is important to consider the effect of expanding the recycled water system on the total river flow. In the future, the Santa Clara River may be affected by the Saugus and Valencia WRPs regardless as to what extent the recycled water system is implemented. If the proposed expansion of the recycled water system is not implemented, the effluent from the Saugus and Valencia WRPs would continue to be discharged and average annual discharges to the river would increase by more than 100 percent by the year 2015.

In 1988, CLWA approved a programmatic Environmental Impact Report (EIR) that included a recycled water element. This element included development of 1,700 AF/yr of recycled water and the minimum effluent discharged to the river in 1988 was assumed to be 9.72 mgd for the month of March. This flow was determined by the EIR to have no impact on the environment. Until additional habitat studies are conducted, it is assumed that for the purpose of this Master Plan, the 2000 baseline flow of 16.25 mgd (from Valencia and Saugus WRPs) minus the 1.5 mgd (1,700 AF/yr) currently under development would be discharged to the river. Consequently, future flows above 14.75 mgd would be available for irrigation use.

The impacts on the river habitat and the endangered species from diverting WRP effluent to reuse are beyond the scope of this report. It is recommended that a detailed habitat study be conducted and the minimum flow necessary to maintain the existing habitat be evaluated. Based on this evaluation, additional recycled water diversions may be possible.

7.2 Water Rights Considerations

The ability of CLWA to use recycled water is also constrained by their rights to use the water available. The water rights issues are different for recycled water from the WRPs, oil field produced water, and treated perchlorate-contaminated water.

7.2.1 Recycled Water from LACSD

A determination of rights to treated wastewater is required prior to long-term project expenditures. Ownership of the rights to wastewater is addressed in three separate state laws or codes:

- Clean Water and Water Bond Law of 1978
- California Department of Fish and Game Code, Section 1600
- Water Code, sections 1210, 1211, and 1702

The Clean Water and Water Bond Law of 1978 established that treated wastewater was the property of the treatment facility that produced it and that the producer could sell or transfer its rights to the treated wastewater. In addition, the rights of the treatment facility allowed the treated wastewater to be used for beneficial purposes regardless of the detriment to downstream users. However, the advice of legal counsel for individual determinations and the development of most equitable and least detrimental projects to all affected parties are recommended.

The California Department of Fish and Game Code Section 1600 requires that "any project which will divert, obstruct or change the natural flow or bed, channel or bank of any river, stream or lake designated by the department in which there is at any time an existing fish or wildlife resource or from which these resources derive benefit" be modified sufficiently "for the protection and continuance of the fish or wildlife resources." On the Santa Clara River, there are users of river water downstream of both the Saugus and Valencia WRPs, as well as SEAs that support endangered species. Potential impacts to these users and the habitat should be addressed in the environmental documents to be prepared for this proposed recycled water project.

Water Code section 1210 provides that "the owner of a wastewater treatment plant has the exclusive right to treated wastewater as against anyone who has supplied the water to the treatment plant, except as otherwise provided by agreement." However, section 1210 expressly provides that this provision does not affect the treatment plant owner's obligations to any legal user of the discharged treated wastewater. Thus, if downstream or secondary appropriators of wastewater flow are considered to be legal users, the right of producers to recycled water could be limited. Such instances have occurred, most recently in Victor Valley (*Victor Valley Wastewater Reclamation Authority, Order WR 2001-Draft*) in which a treated wastewater change petition was denied on the account of injury to third party water right holders.

Water Code section 1211 requires the SWRCB to review a proposed change in point of discharge, place of use, or purpose of use of treated wastewater in the same manner as the SWRCB would review a proposed change to an appropriative water right. As both sections 1210 and 1211 make clear, however, the Legislature did not intend to affect any rights that downstream users may have to the treated wastewater discharge under the common law. Therefore, Water Code section 1702 provides that before granting permission to make a change, the SWRCB must find "that the change will not operate to the injury of any legal user of the water involved." The statutory "no injury" rule set forth in Water Code section 1702 codifies that common law no injury rule and therefore should be interpreted consistent with case law that interprets and applies the common law rule. Generally, the common law no injury rule precludes a change in the exercise of a water right if, among other things, the change would alter the pattern or rate of return flow to the detriment of downstream water right holders (*Scott v. Fruit Growers' Supply Co., 1972).*

An important limitation to the no injury rule is that downstream water right holders are protected from injury only to the extent that the source of the return flow is "native water," as opposed to "foreign water." Native water is that water that under natural conditions would contribute to a given stream or other body of water (surface water or percolating groundwater). When the source of return flow to a stream is native water, the return flow is considered part of the natural flow of the stream to which riparian and appropriative water rights may attach. The no injury rule does not protect downstream water right holders when the source of the return flow is "foreign water." A common example of foreign water is imported water, or SWP water. Riparian right holders have no right to use return flow from foreign water because riparian rights extend only to the natural flow of the stream.

Groundwater extracted from and used in the Santa Clarita Valley and then discharged to the Santa Clara River as wastewater effluent may be considered a "native water" in the river; however, SWP water imported into and used in the Santa Clarita Valley and then discharged to the Santa Clara River as wastewater effluent is clearly a "foreign water." Furthermore, while it could be argued that the existing discharges have a permanent public use (i.e., habitat), only the "foreign water" percentage within the effluent flows could be diverted for recycling purposes.

why so low

In the year 2000, Santa Clarita Valley's water supply consisted of approximately 46 percent groundwater and 53 percent imported water. Projected water demand for the year 2015 is approximately 91,600 AF, 50 percent derived from foreign water and 50 percent derived from native sources. The projected recycled water component would consist of approximately 45 percent of projected wastewater generation. Table 7-3 presents a water supply analysis for the CLWA service area through the year 2015. The table projects the ratio of annual recycled water use to annual imported water use. The maximum recycled water use projected for 2015 is equivalent to approximately 40 percent of the total foreign water projected for that year.

TABLE 7-3
USE OF NATIVE WATER VS. FOREIGN WATER

	Native Water (AF/yr)	Foreign Water (AF/yr)[(a)]	Recycled Water (AF/yr)	Total (AF/yr)	Wastewater Flow (AF/yr)	Wastewater as a Percentage of Water Use	Foreign Water Portion of Wastewater (AF/yr)
Existing	28,409	32,579	1,700	62,688	18,685	30%	9,973
Future	30,800	47,600	19,000	95,400	38,200	40%	19,000

Note: (a) Foreign water includes SWP water, water transfers, and desalination.

7.2.2 Oil Field Produced Water

Oil field produced water at the Berry Petroleum oil fields is produced during petroleum extraction operations by Berry Petroleum. The rights for water produced with petroleum are generally considered to be subject to the rule of capture and, as such, are owned by the owner of the mineral rights. Thus, water rights to the oil field produced water lies with Berry Petroleum who has the right to sell the oil field produced water to CLWA for beneficial uses.

7.2.3 Perchlorate-Contaminated Water

Perchlorate contamination of four wells was detected in 1997. These wells are located within the Santa Clarita Valley, owned and operated by three separate purveyors: NCWD, SCWC, and VWC. Within the non-adjudicated basin, each purveyor is the owner and operator of their wells, and has an appropriative right to the pumped groundwater. Each purveyor has the right to sell the pumped contaminated groundwater to CLWA for beneficial use.

7.3 Recycled Water Supply Availability

Based on the potential environmental and water rights constraints, a recycled water supply of 15,000 to 19,000 AF/yr appears available if sufficient demand can be developed. Accordingly, a target capacity of 17,000 AF/yr is recommended. A market assessment for recycled water is presented in Section 8. If a habitat evaluation indicates that increased diversions of recycled water can be allowed without adverse impacts, additional recycled water development is recommended.

Section 8: Market Assessment for Recycled Water

In this section, potential recycled water users within the CLWA service area are identified. For each potential user, estimates are provided for annual demand, peak monthly demand, peak daily demand, and the hourly distribution of water demand during peak months. The requirements for potential users to convert their existing water potable systems to recycled water are also discussed.

8.1 Potential Users

Potential recycled water users were identified through a number of sources including:

- 1993 Recycled Water Master Plan
- Water consumption records for LACWD No. 36, NCWD, SCWD, and VWC.
- Land use maps.
- General Plans and Specific Plans for the City of Santa Clarita and County of Los Angeles.
- Discussions with City, County, water purveyor, and land developer staff.
- "Windshield" survey of the CLWA service area.

In order to be considered as a potential recycled water user, the user had to be located within the CLWA service area and have a potential non-potable water demand of at least 4 AF/yr. A preliminary list of potential users and their recycled water demand is included in Appendix A, with their locations shown in Figure 8-1. A total potential demand of 33,249 AF/yr was identified.

Potential users with existing water demands ("existing users") include Six Flags Magic Mountain Amusement Park, several golf courses, freeway and roadway median landscaping, the Civic Center, residential and industrial development, and several schools and parks. Potential users with future water demands ("future users") include additional residential and industrial development, as well as additional golf courses. Table 8-2 summarizes the potential demands attributable to existing and future recycled water users.

TABLE 8-2
EXISTING VS. FUTURE RECYCLED WATER USERS

Type of User	Projected Demand (AF/yr)
Existing	8,375
Future	9,064
Total	17,441

The initial list of potential recycled water users was reduced by evaluating the potential users that it would be most expensive to serve until potential uses were approximately 17,000 AF/yr. The cost per acre-foot to serve each user was calculated using the capital costs for pipelines, reservoirs, and pump stations as well as operational costs for pumping. The areas that were retained for recycled water service had costs per acre-foot ranging from $120 to $5,000. Areas that were eliminated from service had costs as high as $13,000/AF. The resulting recycled water service area centers on Valencia and encompasses a large portion of the CLWA service area.

Table 8-1 presents the final list of potential users to be served by the recycled water system. The locations of the users are shown in Figure 8-2. The user numbers in Figure 8-2 correspond with the user numbers in Table 8-1.

8.2 Potential Recycled Water Demand

Potential annual demands for recycled water were estimated from historical water use records for existing users and the proposed irrigated area and expected water user per acre for future users. Demands for recycled water are seasonal, with the highest demands occurring during the hot, dry summer months when irrigation requirements are greatest. Peak monthly irrigation demands for existing users were assessed based on available historical data. To approximate peak monthly demand for future users, a peak monthly usage factor was calculated for the CLWA service area by dividing the combined peak monthly demand of the existing users by the combined average monthly demand. The peaking factor calculated was approximately 2.25. Peak monthly demands were then estimated by applying the peak monthly factor to each future user's average monthly demand.

Peak daily demands and peak hourly demands for existing potential users were either provided by the user, or estimated based on the number of irrigation days per month and the irrigation hours per day. For future potential users, peak daily demands and peak hourly demands were estimated based on irrigation days and hours provided by existing potential user of the same type (e.g., golf course, school, park).

The estimated annual, peak monthly, peak daily, and peak hourly demands for the recycled water users are shown in Table 8-1. The total annual recycled water demand is approximately 17,441 AF/yr. Total peak monthly demand is estimated to be 3,071 AF and total peak daily demand is estimated to be 101 AF.

During the peak month, recycled water demand is anticipated to be highest between the hours of midnight and 6:00 a.m., as most irrigation customers irrigate at night. This is due partly to water efficiency and horticultural benefits, but is also a requirement of DHS to limit public contact. Demand during the peak demand period is expected to be 65,230 gpm.

8.3 Conversion Requirements

DHS and the California/Nevada Section of AWWA have prepared guidelines for use of recycled water, which are based on the reclamation criteria set forth in Title 22 and discussed in Section 5.3.2. The guidelines address the steps that should be taken in converting potable water systems to recycled water systems. Two primary goals of the guidelines are to prevent potable water systems from being contaminated by recycled water and to make the public aware that recycled water is being used.

For users with separate irrigation and potable water systems, the primary requirement will be to disconnect the irrigation system from the potable water service and connect it to the recycled water service. Reduced pressure principle backflow prevention devices will need to be installed on the potable service immediately downstream of the meter. For those users with irrigation systems that tie to their potable water systems at several locations, the systems will have to be separated. Additionally, hose bibbs will need to be eliminated from the irrigation systems.

TABLE 8-1
PROPOSED RECYCLED WATER USERS

Public areas, such as golf courses, parks, and schools, will need to post signs warning the public that recycled water is being used for irrigation. Parks, schools, and other users with exposed drinking fountains near landscaped areas will have to provide shields to prevent recycled water from coming into contact with the drinking fountains.

The cost of these conversion requirements are assumed to be incurred by the users; however, CLWA may adopt a policy to assist with onsite conversion costs. In general, the costs are anticipated to be relatively low. Costs will vary from user to user because the cost will depend on meter size and complexity of the irrigation system.

Section 9: Seasonal Storage Opportunities

As discussed in Section 7, effluent from both the Saugus and Valencia WRPs is currently discharged to the Santa Clara River. Implementation of the proposed recycled water system would reduce effluent discharged to the river. As recycled water demand is highest in the summer and lowest in the winter, seasonal storage may mitigate potential impacts to the river flow and enable additional recycled water supply to be available during high water use months.

9.1 Seasonal Supply and Demand Balance

Due to the need to maintain flow in the Santa Clara River, differences in the monthly production and use of recycled water affect total annual use. The Valencia WRP produces recycled water at a more or less uniform rate throughout the year. Oil field produced water and treated perchlorate-contaminated water are also produced throughout the year. CLWA would receive recycled water from Newhall Ranch WRP only during winter months. However, since most recycled water is used for irrigation, demand peaks during the summer months and is significantly less during the winter months. As a result, recycled water production may not be adequate to meet demands in summer months, while in winter months, surplus effluent may exist. To meet peak summer demands, either potable water must be used to supplement the non-potable supply or seasonal storage for recycled water must be provided.

In 2000, approximately 12.08 mgd was discharged to the Santa Clara River from the Valencia WRP and 4.81 from the Saugus WRP during the peak irrigation month (July). Peak day demands for the recycled water system are anticipated to total 32 mgd. If served by recycled water, these demands would not allow for any recycled water to be discharged to the river from the Valencia WRP during the peak irrigation months. Projected recycled water demand and available supply are shown on Table 9-1 and in Figure 9-1. The recycled water demand pattern was estimated based on evapotranspiration data from DWR.

Based on this analysis, it would be desirable to provide seasonal storage to optimize recycled water utilization. The feasibility of seasonal storage is addressed in the following section.

9.2 Seasonal Storage Options

The 1993 Reclaimed Water Master Plan addressed two potential seasonal storage options: Charlie Canyon and Oak Spring Canyon sites for open aboveground reservoirs. In addition to aboveground reservoirs, aquifer storage and recovery (ASR) appears to be a potential approach to providing seasonal storage.

9.2.1 Aboveground Seasonal Storage

The 1993 Reclaimed Water Master Plan addressed the feasibility of seasonal storage in an aboveground reservoir. The list of potential sites was narrowed down to two, Charlie Canyon and Oak Spring, based on proximity to existing and planned development, to existing faults, or to the proposed recycled water system. These two sites are shown on Figure 9-2.

TABLE 9-1
PROJECTED RECYCLED WATER DEMAND VS. SUPPLY FOR YEAR 2010

Month	Required Baseline Flow (mgd)	Available Supply (mgd)[(a)]	User Demand (mgd)	Excess (+) / Deficit (-) (mgd)
January	14.75	19.40	0.00	+19.40
February	14.75	20.02	0.00	+20.02
March	14.75	19.94	4.74	+15.20
April	14.75	20.54	15.55	+4.98
May	14.75	20.97	24.41	-3.44
June	14.75	22.01	30.75	-8.73
July	14.75	22.55	30.75	-12.88
August	14.75	22.94	33.94	-11.00
September	14.75	21.58	25.39	-3.81
October	14.75	21.87	18.18	+3.69
November	14.75	21.31	3.19	+18.12
December	14.75	20.66	0.10	+20.56
Average	14.75	21.15	17.42	+3.78

Note: (a) Available supply is total supply minus required baseline flow.

9.2.1.1 Reservoir Capacity

The Charlie Canyon site can provide up to 6,300 AF of water storage. The Oak Spring Canyon can provide up to 12,500 AF of additional water storage. Reservoir capacity should provide storage for maintenance of the minimum target river flow as well as for evapotranspiration. The reservoir should also have a minimum pool, which can equal up to one-third of the total capacity of the reservoir.

9.2.1.2 Reservoir Operation

The two reservoir sites selected allow for two approaches to mitigate potential impacts to the river habitat. The Charlie Canyon site would allow excess supply to the discharged directly to the Santa Clara River. Water from the reservoir released to Castaic Creek would supplement the discharge from the WRPs during May through October, maintaining the target flow for the river beginning at the confluence of Castaic Creek and the Santa Clara River.

The Oak Spring Canyon site would allow for pumping of excess supply up to Oak Spring Canyon, where it would be discharged and supplemented with water from the reservoir released to Oak Spring Creek. The minimum target flow would be maintained beginning at the confluence of Oak Spring Creek and the Santa Clara River.

Reservoir operation would generally follow this pattern:

- Deliver recycled water to reservoir for 5 months each year (November through March).
- Release water from reservoir for 6 months each year (May through October).

9.2.1.3 Facility Requirements and Preliminary Cost Estimates

Preliminary cost estimates for the two alternative reservoir sites, including the cost of necessary distribution system improvements, are presented in Table 9-2. Reservoir costs assume an earthfill dam. As shown, the Charlie Canyon Reservoir is estimated to cost approximately $11.6 million. The Oak Spring Canyon reservoir is estimated to cost approximately $29.4 million. These estimates are conceptual and only represent estimated capital costs; additional detailed study would be required to further evaluate the feasibility of these reservoirs, including environmental studies, necessary documents for CEQA compliance, watershed investigations, hydrogeologic studies, geotechnical investigations, and seismic investigations.

TABLE 9-2
PRELIMINARY CAPITAL COST ESTIMATES FOR SEASONAL STORAGE RESERVOIR ALTERNATIVES

Component	Estimated Cost (2002 Dollars)	
	Charlie Canyon	Oak Spring Canyon
Reservoir	$5,259,000	$6,959,000
Additional Piping to Reservoir	$285,000	$1,748,000
System Upgrades	$0	$5,320,000
System Flushing/Testing	$10,000	$61,000
Subtotal	$5,554,000	$14,087,000
Mobilization/Demobilization (10%)	$555,000	$1,409,000
Taxes (8.25%)	$504,000	$1,278,000
Contractor OH&P (18%)	$846,000	$2,147,000
Design Allowance (20%)	$1,492,000	$3,784,000
Engineering (10%)	$895,000	$2,271,000
Legal/Admin (2%)	$197,000	$500,000
Construction Management (5%)	$502,000	$1,274,000
Contingency (10%)	$1,055,000	$2,675,000
Total Cost	$11,601,000	$29,425,000

Note: Cost estimates were prepared by adjusting the cost estimates for the 1993 Reclaimed Water Master Plan by the appropriate ENR factor. Property acquisition and additional studies are not included.

9.2.1.4 Advantages and Disadvantages of Aboveground Seasonal Storage

Aboveground seasonal storage of recycled water is difficult to implement because sites must be close to the proposed recycled water system, but sufficiently distant from existing and planned development and faults. The canyon sites that often offer the best topography for storage often involve environmental obstacles that are difficult to overcome. Permitting can also be a substantial challenge. The construction of aboveground storage reservoirs is generally expensive.

In addition, the retail water purveyors have wells along the river that draw water from the alluvial aquifer, downstream of the WRPs discharges. If recycled water is released to the river upstream of these wells, DHS may consider the water to be a potential source of waterborne contamination for the wells and may require disinfection under the Surface Water Treatment Rule, which applies to groundwater under the influent of surface water, or the Groundwater Rule. The potential impact on the retail water purveyors should be evaluated.

Finally, aboveground seasonal storage reservoirs offer operational challenges. During the many months when the reservoir is full, algae have the opportunity to grow, creating water quality problems. Disinfection or other treatment becomes necessary, further increasing both capital and operational costs.

9.2.2 Aquifer Storage and Recovery

Instead of storing recycled water in aboveground seasonal storage reservoirs, ASR could be used. During the wet winter months, when recycled water production is at its peak, but demand is low, recycled water could be injected into the Saugus Formation north of the San Gabriel Fault where potable water wells would be separated from recycled water ASR facilities by a fault. During the dry summer months, when demand is highest, the recycled water would be extracted and delivered to customers. ASR avoids the significant siting issues associated with aboveground seasonal storage. Additionally, there is no evapotranspiration loss.

9.2.2.1 Regulatory Requirements

The Draft Groundwater Recharge Regulations discussed in Section 5 apply to planned groundwater recharge projects using recycled water and located in a groundwater basin identified designated in the Basin Plan as a source or potential source of domestic water supply. All of the subbasins of the Eastern Groundwater Basin are designated as being an existing source of domestic water supply. When the regulations are finalized and adopted, any ASR project using recycled water would be subject to these regulations and their requirements for monitoring and reporting. However, based on the definition of recycled water contained in the regulations, an ASR project that only involved treated oil field produced water may not be considered recycled water.

9.2.2.2 Hydrogeology North of the San Gabriel Fault

As discussed in Section 4.1.1.2, there are two freshwater bearing aquifers, the Alluvial and Saugus aquifers, within the CLWA service area. In 1990, the use of the Saugus Formation for conjunctive use was evaluated. At that time, the idea was to inject SWP water during wet years and withdraw it during dry years, when SWP deliveries are curtailed. Subsequently, the VWC demonstrated the feasibility of ASR in an area south of the San Gabriel Fault. Many of the conclusions of these evaluations are also applicable to aquifer storage and recovery of recycled water.

The Saugus Formation underlies approximately 53 square miles of the Santa Clarita Valley in Los Angeles County, and combined with the alluvial deposits from the Santa Clara River and its tributaries, comprises the water-bearing sediments of the Eastern Groundwater Basin. The CLWA boundaries encompass the aquifer almost in its entirety.

Two faults cross the Saugus Formation, dividing it into three parts, each with different characteristics. The San Gabriel Fault traverses the Saugus Formation in a northwesterly direction, while the Holser Fault extends westerly across the aquifer from the San Gabriel Fault. Generally, the aquifer characteristics are best between the two faults and worst north of the San Gabriel Fault. Due to the poor aquifer characteristics north of the San Gabriel Fault, this area is not generally used for the production of drinking water, making it the best location for aquifer storage and recovery of recycled water. Figure 9-3 presents the area where ASR is most likely to be feasible.

The Saugus Formation is comprised of layers of water-bearing deposits. The maximum thickness of the Saugus deposits bearing fresh water varies from 1,500 feet north of the San Gabriel Fault, to 5,000 feet south of the Holser Fault, to 5,500 feet between the two faults. Of the fresh water-bearing deposits, a portion is fine-grained strata, such as siltstones and shales and, therefore, is unsuitable for groundwater storage and extraction. The remaining sand and gravel deposits are potentially usable water-bearing strata for ASR. The maximum combined

K/J 014642.00

Figure 9-3

thickness of these strata between the depths of 500 feet and 2,500 feet are 400 feet north of the San Gabriel Fault. The 500-foot minimum depth ensures no interference of groundwater from the alluvium and the 2,500-foot maximum depth recognizes the increased costs of pumping at deeper depths.

The Saugus Formation is a confined aquifer, resulting in piezometric water surface elevations in wells as high as several hundred feet above the top of the well perforations. Transmissivity through the aquifer, a measure of the rate water is transmitted through a unit width of aquifer ranges from 80,000 to 160,000 gpd/ft.

9.2.2.3 Water Quality Requirements

Groundwater in the Saugus Formation is generally of calcium bicarbonate or calcium-magnesium sulfate character. In the region north of the San Gabriel Fault, most of the area has theoretical TDS values of more than 800 ppm.

Table 9-3 presents the water quality objectives for the Santa Clara-Bouquet and San Francisquito Canyons portion of the Eastern Groundwater Basin according to the Basin Plan.

TABLE 9-3
BASIN PLAN WATER QUALITY OBJECTIVES

Constituent (units)	Basin Plan Objective	Recycled Water (Valencia WRP)	Oil Field Produced Water	Treated Perchlorate-Contaminated Water[a]
TDS (mg/l)	700	739	145	1,000
Sulfate (mg/l)	350	135	NA	250
Chloride (mg/l)	150	170	NA	250
Boron (mg/l)	1.0	0.91	1 - 2	NA

NA - Not Available

Notes: Values are dependent upon the treatment processes ultimately selected.
(a) Assumes that treated perchlorate-contaminated groundwater will meet primary and secondary MCLs.

9.2.2.4 Facility Requirements and Preliminary Cost Estimate

Implementation of ASR would require the construction of the following:

- Wells that can be used for both injection and withdrawal of recycled water.
- Pipeline connecting the wells to the recycled water system.
- Booster pumping station improvements.

Other investigations and studies that should be conducted in order to determine the feasibility of the ASR seasonal storage alternative and to estimate the costs more accurately include the following:

- Environmental studies, including necessary documents for CEQA compliance.
- Hydrogeologic studies.
- Aquifer investigation.
- Water quality/compatibility investigation.

A preliminary cost estimate for ASR seasonal storage, including the cost of necessary distribution system improvements, is presented in Table 9-4. The cost estimate is based on the assumption that fifteen 1,000-gpm wells will be constructed, for a total maximum supplemental seasonal capacity of 15,000 gpm. The cost estimate does not include the cost of the additional studies. As shown, the ASR project is estimated to cost approximately $4.5 million.

TABLE 9-4
PRELIMINARY CAPITAL COST ESTIMATE FOR ASR SEASONAL STORAGE ALTERNATIVE

Component	Cost (2002 Dollars)
Wells	$2,000,000
BPS Upgrades	$250,000
Distribution Pipelines Upgrades	$1,620,000
System Flushing/Testing	$5,000
Subtotal	$3,875,000
Mobilization/Demobilization (10%)	$387,500
Taxes (8.25%)	$351,656
Contractor OH&P (18%)	$590,612
Design Allowance (20%)	$1,040,954
Engineering (10%)	$624,572
Legal/Admin (2%)	$137,406
Construction Management (5%)	$350,385
Contingency (10%)	$735,808
Total Cost	$8,093,893

Note: Property acquisition and additional studies are not included.

9.3 Recommended Seasonal Storage Option

Due to the cost, difficulty in siting, permitting, and obtaining approvals, and the operational difficulties of aboveground reservoirs for recycled water storage, it is recommended that CLWA defer further evaluation of aboveground storage and initiate a feasibility study of recycled water ASR north of the San Gabriel Fault.

Section 10: Recommended Recycled Water System

This section discusses the development of the recommended recycled water system based on the established planning criteria and the system modeling techniques used to confirm its viability. The planning criteria are the concepts and assumptions that ultimately form the service criteria for the system. In addition, the recommended recycled water system is described.

10.1 Planning Criteria

Planning criteria were established for each component of the recycled water system, including the recycled water supply, recycled water pump stations, storage reservoirs, distribution system, and booster pump stations. These criteria are summarized in Table 10-1 and described below. The criteria are generally based on the 1993 Master Plan.

TABLE 10-1
SUMMARY OF RECYCLED WATER SYSTEM DEVELOPMENT CRITERIA

System Component	Criteria
Recycled Water Supply	1. Projected production of recycled water sources (Valencia WRP, oil field produced water, treated perchlorate-contaminated groundwater) determine construction phasing. 2. Assume WRP equalized effluent flow.
Recycled Water Pump Stations	1. Valencia Pump Station limited to 12,000 gpm. 2. Oil field produced water pump station to supply 1,250 gpm. 3. Pumps will operate during peak demand periods.
Storage Reservoirs	1. Provide storage for approximately 75% of the peak day demand. 2. Reservoir elevations should be adequate to provide consistent delivery pressures to most users.
Distribution System	1. Size to meet the peak hour demands. 2. Maximum design velocity is 6 fps. 3. Maximum system pressure is 185 psi. 4. Optimum delivery pressure is 55 to 150 psi. 5. All buried piping is "purple" high-pressure PVC up to 24-inch and steel or ductile iron pipe is used for larger sizes.
Booster Pump Station	1. Size for peak day demands. 2. Size in order to operate during off-peak electrical hours in order to minimize energy costs.

10.1.1 Recycled Water Supply

Recycled water would be supplied to the recycled water system by the Valencia WRP. If available, oil field produced water and treated perchlorate-contaminated water would also be used in the non-potable system. Effluent from Newhall Ranch WRP would be transferred to the system during the wet winter months.

10.1.2 Recycled Water Pump Station

A 4,000-gpm recycled water pump station has been constructed at the Valencia WRP as described in Section 10.2.1. The recycled water pump station capacity is dependent upon plant production and effluent flow patterns, as well as recycled water demand. The ultimate pump station capacity at Valencia WRP is planned to be 12,000 gpm. A 1,250-gpm recycled water pump station would be constructed to pump oil field produced water into the system

Storage capacity would provide reductions in the required reuse pump station capacity by allowing peak hour demands to be met with a combination of pumped water and water from storage reservoirs. The recycled water pump stations would be controlled by water surface elevations in the storage reservoirs.

10.1.3 Storage Reservoirs

The storage capacity to be provided for the recycled water system is equivalent to approximately 75 percent of the peak day demand. Reservoir elevations would be determined by the required system and delivery pressures as discussed later in this section.

10.1.4 Distribution System

Distribution system design is dependent upon flow, velocity, and pressure criteria. The distribution system would be sized to handle the peak hour demands. High velocities, which may reduce the useful life of the pipeline and increase energy requirements to delivery water, are not desirable. Maximum design flow velocity in the system would be 6 feet per second.

Two pressure criteria were considered in the planning of the system. Defined as the pressure at any point within the distribution system, system pressure is dependent upon reservoir levels, recycled water demands, and pumping conditions. The maximum system pressure would be 185 pounds per square inch (psi). Delivery pressure refers to the pressure at which recycled water is delivered to the users. Optimum delivery pressure ranges from 55 psi to 150 psi.

10.1.5 Booster Pump Stations

The function of the booster pump stations is to boost the system pressure from a lower zone to a higher zone. The stations should be designed to meet the peak day demand of the higher zones. They should also be sized large enough to operate during off-peak electrical hours. The criteria for system pressure and delivery pressure discussed in the previous section also apply to design of the booster pump stations.

10.2 Existing Recycled Water Infrastructure

Based on the Reclaimed Water Master Plan prepared in 1993, CLWA has constructed or is in the process of constructing several improvements as described below and shown in Figure 10-1.

10.2.1 Recycled Water Pump Station

The recycled water pump station is located at the Valencia WRP. It has a capacity of 4,000 gpm and connects to the existing chlorine contact basin. The recycled water pump station will pump into pipeline IA-2.

10.2.2 Pipeline

Recycled water pipeline IA-2 is currently under construction. It includes 15,600 LF of 20- and 24-inch ductile iron pipe from the Valencia ~~WRP recycled~~ water pump station to recycled water reservoir no. 1.

10.2.3 Reservoir

Recycled water reservoir no. 1 is now under construction. It is a 1.5 mg aboveground steel reservoir located near the proposed Westridge Golf Course.

10.3 Recommended Service Policies

To develop the recommended recycled water system, key service policies must be considered. Because specific service policies have not been established by CLWA, policies necessary for the development of a recycled water system are recommended. Among the recommended service policies upon which the recommended recycled water system is based are:

1. Although retail service by CLWA is limited to areas prescribed by statute, CLWA would provide the facilities to deliver recycled water to individual existing and future users identified as each implementation phase is developed.
2. For new development tracts which plan or are conditioned to utilize recycled water, CLWA would provide the facilities to deliver recycled water to the boundary of the tract or to a location reasonably near the tract.
3. Facilities located within planned public right-of-way of new development tracts must be dedicated to CLWA or the retail service provider.
4. At CLWA's convenience and discretion, CLWA may construct transmission facilities through new development tracts.
5. Onsite facilities for new or existing users will be provided by the user. However, CLWA may develop an incentive program to fund onsite retrofits.

10.4 Components of the Recommended Plan

Serving approximately 168 users, the recommended recycled water system is divided into two service zones based on the topography of the service area. Each of the zones would contain

Figure 10-1

K/J FILE: X:\DWG\014642\FIGURES-5.DWG REV. DATE: 5/14/2002 storage reservoirs, distribution system piping, and booster pump stations. The reuse pump station is located at Valencia WRP, the main source of recycled water supply. A second source water pump station would be located at the oil field produced water facility. The proposed layout of the recycled water system is shown in Figure 10-2. Flow and storage information for each of the zones is presented in Table 10-2. Figure 10-3 shows the extents of the 1430 and 1680 pressure zones.

TABLE 10-2
FLOW AND STORAGE DATA BY ZONE

Service Zone	Peak Day Demand (mgd)	Peak Hour Demand (gpm)	Storage Volume (mg)
1430	22.9	43,812	17.5
1680	9.0	22,870	6.75
Total	31.9	66,682	24.25

Note: (a) Assumes recycled water pump stations operate 24 hours per day.

10.4.1 Recycled Water Supply

Recycled water would be supplied to the system from the Valencia WRP, as well as the Placerita oil field and the perchlorate removal treatment plant (temporarily). During periods of peak demand, water would also be supplied from ASR facilities.

At the Valencia WRP, treated wastewater is diverted from the chlorine contact tank via an overflow weir to the reuse pump station. The total system demand for recycled water is approximately 17,441 AF/yr, most of which would be used from May through October.

The recycled water supply from the Valencia WRP would be slightly reduced during filter backwashing. Valencia WRP has 14 filters, which are backwashed throughout the day (20 minutes per filter ever 1.7 hours). When filters are backwashing, the system would still be supplied from the storage reservoirs, oil field produced water, and ASR facilities, and a portion of the Valencia WRP flow would still be available.

10.4.2 Recycled Water Pump Stations

The recycled water pump station is located near the chlorine contact tank at the Valencia WRP and would be used to transport the recycled water to the storage reservoirs in each zone. It is currently sized for 4,000 gpm. Assuming constant flow rate and total daily flow equivalent to the peak day demand, the ultimate capacity of the reuse pump station is 12,000 gpm.

A second recycled water pump station would need to be constructed at the oil field produced water facility. The capacity would be 1,250 gpm and the pump station would be located at the Placerita oil field in the 1680 zone.

10.4.3 Storage Reservoirs

The recommended plan includes construction of 8 recycled water storage reservoirs. Each zone would have at least one reservoir. The storage capacity in each zone would be equal to 75 percent of the peak day demand. The reservoirs are assumed to be aboveground steel tanks and would range in size from 1.5 mg to 3.5 million gallons. Total storage capacity for the system is 24.5 million gallons. Recycled water entering and exiting the storage reservoirs would be controlled by two-way flow altitude valves. Storage reservoir locations are shown in Figure 10-1 and reservoir capacities listed in Table 10-3. The reservoir elevations are determined by the system and delivery pressures and are also listed in Table 10-3.

TABLE 10-3
RESERVOIR VOLUMES AND ELEVATIONS

Reservoir Number	Service Zone	Volume (mg)	Maximum Water Surface Elevation (ft)
1[(a)]	1430	1.5	1430
2	1430	3.0	1430
3	1430	3.25	1430
4	1430	3.0	1430
5	1430	3.5	1430
6	1430	3.25	1430
7	1680	3.5	1680
8	1680	3.25	1680

Note: (a) Under construction.

10.4.4 Distribution System

The proposed pipeline routes for the recycled water system are shown in Figure 10-1. The routes are located along existing public rights-of-way and planned roadways, where possible, to maintain accessibility and minimize the costs of acquiring pipeline easements. The distribution system consists of approximately 275,000 lineal feet (LF) of pipe ranging from 8 to 36 inches in diameter. The lengths and diameters of the pipeline segments for each zone are presented in Table 10-4. High-pressure polyvinyl chloride pipe (PVC) pipe is the primary pipe type used throughout the system. In addition, steel pipe is required at bridge crossings and ductile iron pipe (DIP) at pump stations and reservoirs.

TABLE 10-4
PIPELINE DIAMETERS AND LENGTHS

Diameter (in.)	Material	Length (LF)
36	Steel	64,182
24	PVC	34,696
20	PVC	40,718
18	PVC	15,008
16	PVC	10,946
14	PVC	31,752
12	PVC	20,190
10	PVC	22,501
8	PVC	44,935

Note: Only includes new pipelines. Pipeline 1A-2 is not included.

The proposed system crosses the Santa Clara River in three locations: McBean Parkway, The Old Road, and Sierra Highway. It is recommended that the pipelines be supported from existing bridge crossings. It is also recommended that the pipeline be supported from existing bridge crossings across freeways. Pipelines cross the I-5 at Rye Canyon Rd. and Valencia Blvd. and State Route 14 (Antelope Valley Freeway) at Placerita Canyon Rd. Air release valves would be installed at the high points of the distribution system to remove trapped air, and blow off valves would be installed at the low points of the distribution system to remove sediment.

10.4.5 Booster Pump Stations

The recommended plan includes one booster pump station in addition to the recycled water pump stations located at Valencia WRP and the oil field produced water facility. The booster pump station is needed in the 1680 service zone to increase system and delivery pressures. The existing Honby Pump Station is planned to be taken out of potable water service within the next few years. This pump station could be modified to provide recycled water service. Its location is shown in Figure 10-1 and capacity information is listed in Table 10-5.

In addition, users with pressures less than 55 psi may require independent booster pumps stations.

TABLE 10-5
BOOSTER PUMP STATION CAPACITY

Booster Pump Station Number	Zones Served	Capacity (gpm)
1	1680	5,000

10.5 System Modeling

After the demands were identified (as described in Section 8) and preliminary layout and sizing of pipelines, reservoirs, and pump stations was performed, the system was modeled. Computer modeling was performed using H2ONET version 3.1, which runs as a module to AutoCAD 2000.

10.5.1 Model Construction

The model accurately represents the proposed model system geometry and major facilities. Because CLWA has very few existing recycled water facilities, the location and characteristics of each feature (e.g., pipe, junction, reservoir) were developed using the planning criteria was manually drawn in AutoCAD. H20Net creates and manages databases to store the input information such as pipe diameters, pipe length, loss coefficients, node demands, and other operating parameters.

Pressure zones were developed based on the topography of the area. Individual demands or geographically close groupings of demand were each assigned to a node. Nodal elevations were determined from a topographic map. Pipelines were located to connect the demand nodes with each other and with the recycled water sources. Pipelines were located in existing and planned streets wherever possible.

Reservoirs were sited for each zone in areas of the appropriate elevation and where land may be available for their construction. Pump stations were sited as needed to maintain adequate pressures throughout the system.

10.5.2 System Evaluation

Flow analysis of the system was performed for the ultimate projected peak hour demands of the customers. Most irrigation customers irrigate at night, which is when the peak hour demand would likely occur. Modeling was performed using a Hazen-Williams coefficient of C = 145.

Velocities, headloss, pressures, and reservoir elevation were tracked throughout the simulated operation period so that the critical or limiting conditions of the system could be identified and corrections made. H2ONET has the ability to display simulation results not only in tabular form, but also in graphical form to aid in rapidly identifying system deficiencies by geographic region or pressure zone. H2ONET can display all nodes that fail to exceed a minimum required pressure under any system demand and can display color-coded directional arrows to identify the lines of major flow in the system.

The recommended recycled water was successfully modeled, meeting all of the planning criteria.

10.6 Cost Estimates

The costs of the recycled water system include both capital costs and O&M costs.

10.6.1 Capital Costs

Table 10-6 presents the criteria used in estimating capital costs for the components of the recycled water system. Cost estimates presented in this report are order-of-magnitude type estimates expected to be accurate within ± 25 percent. The cost estimates were developed from general cost curves, information suppliers, other studies, and Kennedy/Jenks Consultants' previous experience.

Reservoir construction costs include costs for grading, materials, and construction. Pipeline construction costs assume in-street construction with a moderate degree of utility crossings and include such items as valves, traffic control, and road resurfacing. Booster pump station costs consist of costs for all materials, equipment, construction, and testing; costs were halved for modifications to existing pump stations. The Santa Clara River and freeway crossings assume supporting of the pipelines on the bridges. System flushing and testing costs assume that approximately 1,000 feet of pipe will be tested per day. The costs do not include pipeline easements and pump station/reservoir property costs.

The estimated capital cost of the recycled water system is approximately $68 million. Table 10-7 summarizes these costs. Capital costs include mobilization and demobilization, taxes, mark up for contractor overhead and profit, legal/administration, engineering, design allowance, construction management, and a contingency.

The cost estimates were developed to provide a reference for financial planning. The actual construction cost and project cost will depend on the final project scope, the schedule for construction, and market conditions at the time of construction. Feasibility of the project and funding needs must be considered and reviewed thoroughly in order to select the proper option and to provide adequate funding.

TABLE 10-6
COST CRITERIA

Component	Unit Cost[a]
Reuse Pump Stations[b]	Based on curve
Reservoirs[b,c]	Based on curve
Pipelines	
36-inch Steel	$405/LF
24-inch PVC	$165/LF
20-inch PVC	$148/LF
18-inch PVC	$129/LF
16-inch PVC	$112/LF
14-inch PVC	$95/LF
12-inch PVC	$91/LF
10-inch PVC	$80/LF
8-inch PVC	$65/LF
Santa Clara River Crossings	$6.15/diameter-inch/LF
Freeway Crossings	$6.15/diameter-inch/LF
Booster Pump Stations	Based on curve
System Flushing and Testing	$1.25/LF

Notes:

(a) All unit costs represent installed costs, including taxes (8.25% on materials only), contractor overhead and profit (18%), design allowance (20%), engineering (10%), legal/administration (2%), construction management (5%), and contingency (20%). Costs do not include land acquisition or right-of-way.

(b) Costs are based on curves developed for typical reservoir and pump station costs. Reservoir costs were estimated based on $/MG and pump station costs on $/gpm.

(c) Includes tank, foundation, appurtenances, excavation, paving, fencing, landscaping, and telemetry.

TABLE 10-7
PRELIMINARY ESTIMATE OF CAPITAL COST

Component	Estimated Cost (2002 Dollars)
Recycled Water Pump Stations	
Expansion of Valencia to 12,000 gpm	$930,000
Oilfield-Produced Water Pump Station	$437,500
Reservoirs	
1	Under Construction
2	$960,000
3	$980,000
4	$960,000
5	$980,000
6	$975,000
7	$980,000
8	$975,000
Distribution Pipelines	
36-inch Steel	$25,994,000
24-inch PVC	$5,725,000
20-inch PVC	$6,026,000
18-inch PVC	$1,936,000
16-inch PVC	$1,226,000

Component	Estimated Cost (2002 Dollars)
14-inch PVC	$3,016,000
12-inch PVC	$1,837,000
10-inch PVC	$1,800,000
8-inch PVC	$2,921,000
Booster Pump Stations	
Modify Existing Honby Pump Station	$1,043,000
Santa Clara River Crossings	$267,000
Castaic Creek Crossing	$52,000
Freeway Crossings	$246,000
System Flushing and Testing	$350,000
Seasonal Storage (ASR)	$8,093,000
Total	$68,710,000

10.6.2 Operating and Maintenance Costs

An economic analysis was performed for the proposed recycled water system. In order to calculate the unit cost, the annualized capital cost was added to the estimated annual operations and maintenance (O&M) cost. The total annual cost (annualized capital and O&M) was then divided by the estimated recycled water demand for each phase to obtain the unit cost. Water purchase costs are discussed in Section 10.6.3.

Annualized capital costs were calculated based on a 20-year period at a 6 percent interest rate. Annual O&M costs were estimated by combining estimated pumping costs, parts cost, and labor costs. Pumping costs were estimated based on 82 percent pump efficiencies, 95 percent motor efficiencies, and an electricity cost of $0.12 per kilowatt-hour. Parts costs were estimated to be 1 percent of construction costs of pump stations and 0.1 percent of construction cost of reservoirs and pipelines. Labor costs were estimated based on 3 man-days per month per phase at $40 per hour.

MAY 04

The total average annual unit cost (2002 dollars), including annualized capital, after implementation of the completed recycled water system is $818 per acre-foot. Because CLWA can utilize available revenue sources funds to repay such debt service, it will not be necessary to recover capital costs through recycled water rates although CLWA may opt to do so. Therefore, the average unit operating cost of recycled water is $59 per acre-foot, excluding the cost of acquiring recycled supplies.

10.6.3 Water Purchase Costs

The cost of purchasing water from Newhall Ranch WRP, the perchlorate-contaminated groundwater treatment facility, Berry Petroleum, and LACSD would be different. Costs of obtaining seasonal excess recycled water from the Newhall Ranch WRP would need to be negotiated with Newhall Ranch. Treated perchlorate groundwater may be available during the 1-2 year DHS demonstration period; there may be a charge for taking this water or it may be available for free. The costs of purchasing oil field produced water would be negotiated with Berry Petroleum. The costs of purchasing recycled water from LACSD are governed by an agreement dated July 1996. The cost of purchasing recycled water from LACSD for the first three years "shall be the greater of:

(a) $5.00 per acre-foot; or

(b) one-half the result determined by subtracting the Castaic Water Reuse Project Costs, as defined below, during the fiscal year divided by the total amount of reclaimed water delivered during the fiscal year, from the Water Rate, as defined below provided that deficits, if any, determined by adding the price to the amount determined by the above calculation may be carried over and considered as part of the Castaic Water Reuse Project's Cost in the next fiscal year."

At the end of the first three years, the cost of purchasing recycled water from LACSD "shall be the greater of:

(a) one fifth of the unit cost...of operation and maintenance of the Water Reclamation Plans, during the fiscal year in which the recycled water was received, rounded to the nearest cent, or

(b) the value determined by the method prescribed in (method b for the first three years)."

Section 11: Permits and Approvals

A number of permits will be required to implement each phase of the recommended plan. These permits are in addition to environmental review requirements under the California Environmental Quality Act (CEQA) or National Environmental Policy Act (NEPA). Because the permitting process can be lengthy, permitting requirements may affect the implementation schedule of the recycled water system. A summary of the permitting requirements is provided in Table 11-1.

11.1 Federal

Implementation of the Master Plan may require several federal permits, specifically from the U.S. Army Corps of Engineers (USACE) and U.S. Fish and Wildlife Services (USFWS).

11.1.1 U.S. Army Corps of Engineers Nationwide Permit

USACE permit authority derives from the Rivers and Harbors Act of 1899 (Section 10), Clean Water Act (Section 404), and Marine Protection, Research, and Sanctuaries Act (Section 103). These regulations give USACE jurisdiction over all navigable waters within the U.S. Approval by USACE is required for construction of structures or work in or work affecting navigable waters of the U.S. Navigable waters include ocean and fresh waters, bays, streams, wetlands, marshes, swamps, and diked lands. USACE has jurisdiction over all of the above even though selected areas may not be navigable.

A Section 10 Permit covers construction, excavation, or deposition of materials in, over, or under such waters, or any work which would effect the course, location, condition, or capacity of those waters. The river crossings proposed as part of the Master Plan would be accomplished by suspending pipelines under existing bridges or boring and jacking under the riverbed. Because some construction activity may occur within the Santa Clara Riverbed, a Section 10 permit would be required.

The USACE issues nationwide permits (NWP), which authorize discharges of dredge and fill material to waters of the U.S. for activities with minimal environmental impacts. The NWP applies to projects of 1/2 acre of impact or less. USACE must be notified of any impacts over 1/10 of an acre. If these thresholds are exceeded, an individual Section 404 permit may be required.

11.1.2 Endangered Species Act Permits

In addition, a biological evaluation may be required to comply with the Endangered Species Act (ESA). Section 7 of the ESA requires all federal agencies to use their authority to conduct conservation programs and to consult with National Marine Fisheries Service (NMFS) or USFWS concerning the potential effects of their actions on any species listed under the ESA. Consultations occur with federal action agencies under Section 7 of the ESA to avoid, minimize, or mitigate the impacts of their activities on listed species. USFWS and NMFS also review non-federal activities which may affect species listed under the ESA and issues permits under Section 10 for the incidental take of those species and for scientific research and enhancement purposes. If endangered species are found within the proposed areas of construction, the Section 10 issuance criteria requires NMFS or USFWS to issue an Incidental Take Permit.

TABLE 11-1
SUMMARY OF PERMITTING REQUIREMENTS

	Agency	Type of Approval	Requirements	Typical Review Period	Comments
Federal Permits	United States Army Corps of Engineers	Nationwide Permit	Needed if affect 1/10 to 1/2 acre of riverbed. Notify USACE of activities.	30-60 Days	Notify USACE of activities
	United States Army Corps of Engineers	Section 10 Permit	Needed if affect course, location, condition, or capacity of river.		
	United States Army Corps of Engineers	Individual Section 404 Permit	Unlikely to be required.		
State Permits	California Department of Fish and Game	Lake or Streambed Alteration Agreement	Construction plans with application	30 Days	Avoid nesting season April through September
	California Department of Fish and Game	Incidental Take Permit	Application	30-120 days	Onsite inspection may be required
	California Department of Transportation	Encroachment Permit	Six sets of construction plans with application	4-8 weeks	Inspection required during construction
	California Department of Health Services	Cross connection control	Construction plans with specifications	Not applicable	Project must conform to Title 22, DHS and AWWA Guidelines
	California Occupational Safety and Health Agency	Trenching and Excavation Permit	Complete plans and specifications	1-2 weeks	Required by contractor
	Regional Water Quality Control Board	NPDES Construction Activity Permit	Application (NOI) before construction starts	60 Days	Required for project area greater than 5 acres
	Regional Water Quality Control Board	Reclamation Permit	Application, Letter, plans, user maps, quantities	6-9 months	LACSD will take lead
	Regional Water Quality Control Board	Engineering Report Requirements	Application, Letter, plans, user maps, quantities	6-9 months	LACSD will take lead
	State Water Resources Control Board	Petition for change in place purpose of use	Petition	Varies	LACSD will take lead

	Agency	Type of Approval	Requirements	Typical Review Period	Comments
Local Permits	City of Santa Clarita	Encroachment Permit	Construction plans with permit application	60 Days	LACSD will take lead
	Los Angeles County Department of Public Works	Excavation Permit	Construction plans with permit application	3-6 weeks	Inspection required throughout construction
	Los Angeles County Flood Control District	Encroachment Permit	Six sets of construction plans with application	60 Days	Inspection required following construction
	Los Angeles County Department of Health Services	Distribution system design & construction approval	Construction plans and specifications	Depends on project	Inspection required following construction, prior to operation
	Los Angeles County Department of Health Services	Onsite (cross connection control) (user) facilities approval	As-built of onsite facilities	Not applicable	Onsite inspection following construction

The decision to grant or deny a permit is dependent upon a public interest review of the probable impacts of the proposed activity and its intended use. Benefits and detriments are balanced by considering effects on conservation, economics, wetlands, wildlife, flood hazards, navigation, water quality, and the needs and welfare of the public. Guidelines restrict discharges into aquatic areas when there are less environmentally damaging, practicable alternatives. Reasonable and practicable mitigation of unavoidable impacts will be required. A permit will be granted unless the project is found to be contrary to the public interest or fails to comply with the guidelines. USACE is required to consult with state and federal wildlife agencies regarding any impacts of a project on aquatic habitats.

11.1.3 U.S. Fish and Wildlife Service Permits

USFWS as part of the Department of the Interior, reviews proposals for work and activities in or affecting navigable waters that are licensed, assisted, or conducted by the federal government, pursuant to the National Environmental Policy Act (NEPA), Estuary Protection Act, Department of Transportation Act, Airport and Airway Development Act of 1970, Watershed Protection and Flood Protection Act, Endangered Species Act, Fish and Wildlife Coordination Act, and other federal legislation and regulations. In addition, USFWS reviews permit applications pursuant to Section 10 of the Rivers and Harbors Act, and Sections 208, 402, and 404 of the Clean Water Act, and other Federal legislation for enhancement of fish and wildlife resources. USFWS staff will identify potential adverse impacts and will propose compensation for irretrievable losses.

USFWS may require the preparation of supplemental biological assessments to determine effects of the proposed project on any federally endangered or threatened fish and wildlife species in or adjacent to the project area. USFWS must evaluate the project and comment prior to the construction and operation of the project. In general, USFWS project review may take 60 to 180 days to respond depending on project complexity and staffing issues.

11.2 State

The following state agencies may require permits and/or approvals for the recycled water system:

- California Department of Fish and Game (CDFG)
- California Department of Transportation (Caltrans)
- California Department of Health Services (DHS)
- State Water Resources Control Board (SWRCB)
- Regional Water Quality Control Board (RWQCB)
- California Division of Occupational Safety and Health (DOSH)

11.2.1 California Department of Fish and Game

CDFG manages California's fish, wildlife, and plant resources, and the habitats upon which they depend, for ecological values and for public use and enjoyment. The CDFG is responsible for issuance of Incidental Take Permits and a Lake or Streambed Alteration Agreement.

11.2.1.1 Incidental Take Permit

Sections 2080 and 2081 of the Fish and Game Code prohibits within the State of California, export out of this State or take, possess, purchase, or sell within this State, any endangered species, threatened species, or species designated as a candidate species under Section 2074.2 of the Fish and Game Code if the Commission has issued notice under Section 2074.4. An Incidental Take Permit must be issued for any projects involving the above stated species. A permit application must be submitted to the Regional Manager. A permit may only be issued if the Director finds that (1) the take authorized by the permit will be incidental to an otherwise lawful activity, (2) the applicant will minimize and fully mitigate the impacts of the take authorized under the permit, (3) the permit will be consistent with any regulations adopted pursuant to Fish and Game Code Sections 2112 and 2114, and/or (4) the applicant has ensured adequate funding to implement the measures required under the permit to minimize and fully mitigate the impacts of the taking, and to monitor compliance with, and the effectiveness of, the measures. On-site inspections may be required prior to a final decision by the Director. The permitting process can take up to 120 days, including a 30-day review period and a 90-day approval/denial period.

11.2.1.2 Lake or Streambed Alteration Agreement

Section 1603 of the Fish and Game Code requires any person who proposes a project that will substantially divert or obstruct the natural flow or substantially change the bed, channel, or bank of any river, stream, or lake or use materials from a streambed to notify CDFG prior to implementation. Notification to CDFG can be accomplished through the submittal of a Notification of Lake and Stream Alteration form (FG 2023) and Project Questionnaire form (FG 2024), along with any other required documents and applicable fees to CDFG. Notification is required for any projects that will take place in or in the vicinity of a river, stream, lake, or other tributaries. This includes rivers or streams that flow at least periodically or permanently through a bed or channel with banks that support fish or other aquatic life and watercourses having a surface or subsurface flow that support or have supported riparian vegetation. Based on the submitted notification, and a possible site visit, CDFG will determine if the proposed project may impact fish or wildlife resources. If CDFG concludes that the proposed project would have a substantially adverse affect on existing fish or wildlife resources, a Lake or Streambed Alteration Agreement from CDFG will be required and reviewed in accordance with CEQA.

11.2.2 California Department of Transportation

An encroachment permit from Caltrans will be required for any work done within the state of right-of-way. This includes installation of a pipeline in a roadway crossing under a highway, support of a pipeline on a bridge crossing over a highway, and activities that impact on-ramp and off-ramp traffic. The proposed system has two pipeline crossings over Interstate 5: McBean Parkway and Valencia Boulevard. A permit application along with six sets of final plans and specifications will be required to be submitted for review and approval. Typical review period is 4 to 8 weeks.

11.2.3 California Department of Health Services

DHS's primary concerns with respect to the recycled water system are cross connections, separation of pipelines, and any activity that has the potential to result in contamination of drinking water. DHS will review plans and specifications prior to construction.

11.2.4 State Water Resources Control Board and Regional Water Quality Control Board

The SWRCB was created by Legislation in 1967 to ensure the highest reasonable quality for waters of the State. Under the SWRCB, there are nine RWQCBs that assist in the implementation of state and federal laws and regulations. The RWQCB regulates the source and the end use of recycled water. Its main involvement in the recycled water system will be through LACSD to modify the reclamation permit to include the specific recycled water users and to review the Engineering Report describing treatment and distribution facilities and users. CLWA's responsibility will be to assist LACSD with preparation of necessary information. In addition, CLWA will need to obtain a NPDES Construction Activity Permit. This permit is required for stormwater runoff from construction projects impacting an area of 5 acres or more. An application (Notice of Intent) must be submitted before construction starts. The review period averages 60 days.

Approval of a Petition for Change of Place and Purpose of Use from the SWRCB is required for any change in discharge location or quantity of wastewater. In 1993, the SWRCB approved a petition for change for the Valencia WRP; however, the amount requested will change according to more recent demand data. In addition, if LACSD pursues the rights to the effluent, review and approval is the responsibility of SWRCB. In either case, LACSD would be the lead agency, requiring assistance from CLWA. SWRCB may also be a potential source of loan or grant funding, as discussed in Section 12.

11.2.5 California Division of Occupational Safety and Health

A Trenching and Excavation Permit from DOSH is required by the contractor for the construction of recycled water pipelines that require trenching deeper than 5 feet. Complete plans and specifications are required along with $50 review and approval fee.

11.3 Local Permits

This section summarizes the anticipated permits and approvals required from local authorities, including Los Angeles County and the City of Santa Clarita.

11.3.1 Los Angeles County Department of Health Services

Plan review and inspection of the distribution system and onsite user facilities to address concerns with drinking water contamination (cross connection control) are required by the Los Angeles County Department of Health Services. LACDHS coordinates with RWQCB and DHS.

11.3.2 Encroachment Permits

Encroachment permits are required for all construction work done within local right-of-way from the City of Santa Clarita, the Los Angeles County Department of Public Works (Excavation Permit) and the Los Angeles County Flood Control District. Two sets of final plans and specifications need to be submitted to the County for encroachments. Fees are based on size of excavation in the right-of-way and on the estimated job costs. Review period averages between 1 to 2 weeks.

11.4 National Environmental Policy Act

Compliance with NEPA would be required if federal funding is acquired. Typically, compliance with NEPA is achieved by preparing an appropriate document evaluating the potential impacts of the proposed project, such as an Environmental Impact Statement or Environmental Assessment. This documentation is similar to that required by CEQA and can be prepared jointly with CEQA documentation.

11.5 California Environmental Quality Act

Preparation of appropriate CEQA documentation will be necessary. CLWA's "Final Program EIR for the Capital Program and Water Plan," including "Acquisition of Supplemental Water and Proposed Second Plant Site," included use of 1,700 acre-feet of recycled water. CLWA's "Site Specific Mitigated Negative Declaration for Construction of a Reclaimed Water Distribution System" included the Phase 1 facilities. It may be desirable to prepare a programmatic environmental document for the Master Plan as well as site-specific CEQA documentation for each implementation phase. The CEQA documentation may be prepared jointly with the NEPA documentation, if NEPA documentation is required.

11.6 Other Institutional Issues

Before providing recycled water service, it will be necessary to secure agreements between the following entities:

- LACSD and CLWA: A contract between LACSD and CLWA is required for sale of recycled water to CLWA and construction and operation of facilities on LACSD property
- Berry Petroleum and CLWA: A contract between Berry Petroleum and CLWA is required for the purchase and use of oil field produced water at the Berry Petroleum oil fields southeast of the City of Santa Clarita.
- Respective purveyors and CLWA: An agreement for temporary use of perchlorate-contaminated groundwater from three local groundwater wells is required between CLWA and the purveyors (NCWD, SCWD, and VWC).
- CLWA and purveyors: Contracts between CLWA and local water purveyors will establish the basis for retail operation of the system and sale of the recycled water.
- Purveyors and users: The agreement between purveyors and users (customer service agreement) will establish the requirements for use of the recycled water and will specify that the users understand the regulations controlling the use of recycled water.

Section 12: Funding and Financing Opportunities

To construct the recycled water system, sufficient capital funds must be secured by CLWA. This section presents a plan for financing the proposed recycled water system. Discussions on financing options, water rate policy, economic analysis and connection fees are included.

12.1 Funding and Financing Alternatives

To finance the construction cost of the proposed facilities, CLWA can obtain capital through the following funding sources:

- Capital Reserves
- Grants
- Low interest Loans
- Certificates of Participation

These potential funding sources are listed in Table 12-1 and discussed in detail below.

12.1.1 Capital Reserves

CLWA receives revenues from facility capacity fees, 1 percent property taxes, water rates and interest on investments. It also has the authority to levy standby charges but has, thus far, not exercised this authority. To the extent that these revenues have exceeded operational expenses, existing debt, and capital expenditures, substantial capital reserves have accumulated. A portion of these reserves is utilized as security for the repayment of certificates of participation. The remainder is available for operating expenses or CLWA's Capital Improvement Program (CIP) in which the recycled water program is included.

12.1.2 Grants and Low Interest Loans

Both the federal and state governments have policies to encourage recycled water projects. These policies have led to several grant and low interest loan programs. Available funds for grants and low interest loans are dependent upon legislative approval and available monies. Those listed in Table 12-1 reflect Fiscal Year 2000-2001 allocations and are likely to be altered in Fiscal Year 2001-2002.

TABLE 12-1
GRANT AND LOAN SUMMARY

	Sponsoring Agency	Funding Authority	Eligible Projects	Total Funds Available	2000-2001 Funds Available/Interest Rate	Applicant Funding Limitations	Grant or Loan
Water Reclamation and Reuse Program	US Bureau of Reclamation	Reclamation Wastewater and Groundwater Study and Facilities Act of 1992 (Title XVI)	Water reuse projects: that reclaim and reuse municipal, industrial, domestic or agricultural wastewater, or naturally impaired groundwater and/or surface waters		25% of total project cost	$20,000,000	Grant
Water Recycling Facilities Planning Grant	SWRCB	Proposition 204	Feasibility studies for water recycling projects	$60,000,000	50% of study costs, not to exceed funding limits	$75,000	Grant
Water Recycling Construction Program	SWRCB	Proposition 204	Wastewater treatment, recycled water storage facilities, pump stations, and recycled water distribution pipelines	$105,000,000	25% of eligible cost	$5,000,000	Grant
Water Recycling Loan Program	SWRCB	Proposition 204	Water recycling projects	$60,000,000	50% of the interest rate paid by the State on the most recent sale of State General Obligation Bonds at a 20-year payback rate	$15,000,000	Loan

	Sponsoring Agency	Funding Authority	Eligible Projects	Total Funds Available	2000-2001 Funds Available/Interest Rate	Applicant Funding Limitations	Grant or Loan
Water Conservation Loan Program	DWR	Proposition 13	Construction of water reclamation storage and distribution facilities, or the purchase of land and land easements for replacement of existing potable water supply		50% of the interest rate paid by the State on the most recent sale of State General Obligation Bonds at a 20-year payback rate	$5,000,000	Loan
Local Water Supply Loan Program	DWR	Proposition 13	Construction of water reclamation facilities to communities for the purpose of supplying additional new local water supplies		50% of the interest rate paid by the State on the most recent sale of State General Obligation Bonds at a 20-year payback rate	$5,000,000	Loan
Agricultural and Urban Water Conservation Loan Program	DWR	Proposition 13	Agricultural and Urban Water Conservation Projects	$16,000,000 for Agriculture $13,000,000 for Urban		None	Loan
Infrastructure State Revolving Loan Program	CA Technology, Trade and Commerce Agency		Water treatment and distribution		Monthly basis	$20,000,000	Loan
Focused Research in Air Quality and Produced Water Management in Oil and Gas Exploration and Production	Department of Energy		Oil field produced water management research	$7,000,000	Maximum 80% of estimated project costs for 1 to 3 years	$1,500,000	Grant

12.1.2.1 U.S. Bureau of Reclamation

The U.S. Bureau of Reclamation's water reclamation and reuse grant program was developed via the Reclamation Wastewater and Groundwater Study and Feasibility Act of 1992 (Title XVI of Public Law [P.L.] 102-575, as amended). This program investigates and identifies opportunities for reclamation and reuse of municipal, industrial, domestic, and agricultural wastewater, and naturally impaired ground and surface waters, for the design and construction of demonstration and permanent facilities to reclaim and reuse wastewater, and to conduct research, including desalting, for the reclamation of wastewater and naturally impaired ground and surface water. The Act also provides a program for federal participation (through cost sharing) of specific water reuse projects up to certain amounts specified in the Act. Construction funds can be provided only for projects specifically authorized by Congress pursuant to Title XVI.

CLWA is currently attempting to obtain Congressional authorization for its recycled water program. Authorization is currently included in HR 1245 (McKeon) and HR 2404 (Miller), which were introduced in the 107th Congress; however, this legislation appears inactive until the CALFED reauthorization bills (S 1768 [Feinstein] and HR 3208 [Calvert]) are addressed. The CALFED bills also include expanded federal programs for recycled water.

12.1.2.2 U.S. Department of Energy National Energy Technology Laboratory

The U.S. Department of Energy (DOE) National Energy Technology Laboratory is currently soliciting applications for cost-shared research projects that address produced water management issues of the oil and gas industry under its Focused Research in Air Quality and Produced Water Management in Oil and Gas Exploration and Production program. The goal of the program is to provide solutions to issues that are limiting domestic production, such as reinjecting oil field produced water. DOE is seeking applicants who can develop technologies to allow the economic beneficial use of produced water, such as landscape irrigation, so as to avoid disposing or reinjecting produced water. DOE is currently anticipating that it will award three to seven projects for a period ranging from one to three years. They are planning approximately $7 million in funding over a 3-year period for this solicitation. Project awards will range from $100,000-$500,000 per year. The minimum required cost share by the project proponents is twenty percent.

12.1.2.3 State Water Resources Control Board

The March 2000 approval of Proposition 13 (2000 Water Bond) provided funds to be allocated by SWRCB for local water-related projects. Roughly $763.9 million was allocated to be available through various bond programs.

The Water Recycling Financial Assistance Program provides grants and low-interest loans for design and construction of water recycling facilities, grants for water recycling facilities planning studies, and grants for recycling research and studies. A total of $53.2 million is available for grants for construction of facilities, $49.5 million in loans for facilities and grants for planning, and $3.2 million for research and studies. The program provides both low-interest loans and grants to local agencies to construct water recycling facilities, provides grants up to $75,000 to local agencies for planning of water recycling facilities, and provides funds for research and studies. Proposition 13 rolls the funds for water recycling from the 1988 Bond Law and 1996 Bond Law into a new Proposition 13 subaccount. Proposition 13 also requires that 60 percent of the funds for design and construction of facilities be allocated to projects in the Counties of

Riverside, Ventura, Los Angeles, San Diego, Orange, or San Bernardino, and that 40 percent of the funds be allocated to projects in the remaining counties. The 1984 Bond Law remains separate, provides low-interest loans up to $10 million for design and construction of facilities, and has no geographic restrictions. Loan applications are supported by facilities planning report demonstrating that the proposed project is cost effective. Loans may be for a period of up to 20 years with an interest rate of 50 percent of the interest rate paid by the state on the most recent sale of State General Obligation Bonds. There is a $15 million limit per project on loans.

12.1.2.4 California Department of Water Resources

DWR has several grant programs available to assist in funding local studies, programs, and projects to better manage California's water resources. It is the primary intent of these programs to fund local activities that will enhance water supply reliability and increase the beneficial use of existing supplies.

The Proposition 13 Water Conservation Program provides low interest loans and grants for construction projects, and grants for feasibility studies to public agencies and incorporated mutual water companies. The Proposition 204 Local Projects program provides low interest loans and grants to local public agencies for water supply construction projects and feasibility studies. The Proposition 82 Local Water Supply program provides only loans for construction projects and feasibility studies.

The Urban and Agricultural Water Conservation Program provides loans to public agencies, and incorporated mutual water companies to finance feasible, cost effective water conservation projects or programs to improve water use efficiency. Projects involving construction of recycled water distribution systems for reuse in lieu of existing potable water supplies are eligible for funding under this program.

The Local Water Supply Construction Loan Program provides loans for the construction of water reclamation facilities to communities for the purpose of supplying additional new local water supplies. Construction of water reclamation storage and distribution facilities, as well as the purchase of land and land easements, is eligible for funding. The maximum loan is $5 million and the interest rate is equal to the most recent California General Obligation Bond sale.

12.1.2.5 California Technology, Trade and Commerce Agency

The Infrastructure State Revolving Fund Program provides low-cost financing to public agencies in amounts ranging from $250,000 to $20,000,000, with a term of up to 30 years. This program supports a variety of projects, including water treatment and distribution.

12.1.3 Certificates of Participation

Certificates of Participation (COP) have been previously utilized to finance capital improvement projects. With a COP, the public entity is not the immediate owner of the facility, but rather becomes the lessee. Another public or private entity may be identified to function as the lessor. The lessor will arrange the financing and construction of the project and then lease it to CLWA. The government unit (such as CLWA) which proposes to occupy or to use the facility initiates the process by agreeing in principle to enter into a contract to lease certain specified property (either real or personal) from lessor. The contract provides the terms and circumstances under which the purchase is divided into periodic installment payments. The payments will include an interest component which may be made annually, semi-annually, or more frequently. To finance the lease, the lessor may then assign to a third party (trustee) its right to receive the installment payments, and the trustee, in turn, provides the financing. The trustee then carves the lease into smaller interests (represented by the certificates) which are underwritten by investment bankers and sold to investors.

The COPs represent (or certify) each investor's percentage ownership in the lease and the entitlement to receive his/her portion of principal and interest payments. Most frequently, certificates are issued in $5,000 denominations. The public agency (lessee) is obligated under the agreement to make the lease payments from lawfully available annual appropriations. Neither the full faith and credit nor taxing power of the lessee is pledged; however, the lease agreement provides that the lessee shall take action each year to include rental payments in its budget. If CLWA is to consider and become a lessee under this type of financing, it must address the source and flow of annual revenues to make rental payments. Installments due under a lease for the facilities would be payable from gross revenues of CLWA. These can include operating revenues, facility capacity fees, and property taxes.

12.1.4 Revenue Sources for Loan/Debt Service Repayment

Capital costs and debt services associated with CLWA's capital improvement program are allocated to existing users and new growth. Costs attributable to existing users are funded by operating revenues and their proportion of the 1 percent property tax, interest on investment, reserves, and standby charges, if levied. Costs attributable to new growth are funded by facility capacity fees and its proportion of the 1 percent property tax interest on investment, reserves, and standby charges if levied.

12.1.5 Recommended Alternative

Due to the numerous grant options and low interest loan programs, CLWA should consider maintaining its accumulated reserves for other purposes and finance the recycled water project through available grant monies and loan programs. It should be noted that a close review of project planning and construction documents is conducted upon application for existing grant and loan programs. Such programs require that the most cost-effective alternative be utilized. The loan programs and majority of grant programs are not retroactive; therefore, the sponsoring agency must approve the project prior to the applicable phase (e.g., feasibility study, planning, construction). It is recommended that coordination with each sponsoring agency listed in Table 12-1 occur immediately following project approval.

12.2 Water Rate Policy

To encourage its use, recycled water should be available at a lower rate to users than potable water. Because recycled water is a reliable source of supply, this cost differential should provide potential customers with the necessary encouragement to use recycled water. The wholesale rate of potable water currently averages $145 per acre-foot among the three purveyors. The retail rate of potable water in the Santa Clarita Valley is approximately double the wholesale rate. The principal wholesale rate strategies for recycled water are discussed below.

12.2.1 Rates Based on Costs of Service

The wholesale recycled water rate could be set at a level to recover costs of furnishing the recycled water. The estimated annualized capital and operating cost of the recycled water system in 2002 dollars is approximately $818 per acre-foot, which is significantly greater than the $145 per acre-foot wholesale or current retail rate for potable water.

Regardless of the program utilized to finance the recycled water system, the basic source of funds is the facility capacity fees, standby charges, property taxes, and water rates currently collected by CLWA. Therefore, it is not necessary to include annualized capital in the cost of service since the capital costs do not need to be recovered. The estimated cost for the recycled water system excluding annualized capital costs is approximately $48 per acre-foot (2002 dollars), which is actually lower than the current wholesale rate for potable water.

12.2.2 Rates Based on Percentage of Potable Water Rate

Although the wholesale recycled water rate should reflect the actual cost of providing service, it may be preferable for CLWA to base its recycled water rate on a percentage of the potable water rate. This is desirable when a straightforward method of calculation is preferred. Often, this method is necessary because the rate based upon costs of service exceeds the potable water rate. Based on the need to provide an incentive to utilize recycled water, a recycled water rate of 70 to 90 percent of the potable water rate is typical.

12.2.3 Rates by User Class

A method used by some water agencies for setting recycled water rate is to establish different rates for various user categories. For example, the Irvine Ranch Water District charges a rate for commercial/landscape users, including homeowner associations, that is approximately nine percent greater than the rate charged for the larger/agricultural users. Because the cost of furnishing recycled water would not differ substantially between types of customers, it seems appropriate for users of CLWA's recycled water system to be initially charged at the same rate. However, a rate surcharge may be appropriate for users of high-pressure water since pumping costs are higher.

12.2.4 Recommended Rate Policy

It is recommended that CLWA utilize a wholesale recycled water rate equivalent to the potable water rate of $145 per acre-foot and that the water purveyors utilize a retail recycled water rate equivalent to the potable water rate. The estimated cost of service for the recycled water system is $818 per acre-foot (2002 dollars) as discussed in Section 10. Utilizing the potable rate for recycled water allows CLWA to recover the cost of recycled water service while avoiding potential problems that investor-owned water companies may face when presenting a recycled water rate case to the Public Utilities Commission and while assuring that the water purveyors experience no loss in revenue.

In order to provide an incentive to recycled water users, it is recommended that the CLWA issue a monthly rebate directly to each recycled water user. The recommended initial rebate is $60 per acre-foot. Based on existing retail potable water rates, the rebate would result in a cost incentive for recycled water users of 20 to 25 percent over potable water rates.

Section 13: Implementation Plan

Section 10 identified recommended infrastructure improvements for a recycled water system in the CLWA service area. This section presents a plan for implementing the recommended system. The discussion focuses on the implementation plan, permit requirements, other institutional issues and the implementation schedule.

13.1 Implementation Considerations

In order to implement each phase, several development activities need to occur and issues need to be addressed. Many of the implementation elements apply to all the phases; however, some issues are unique to individual phases or facilities. The following is a listing of the major activities and issues to be addressed which are common to all phases. The activities are generally listed in order of occurrence; however, most would require concurrent effort through the duration of implementation.

- Customer Development - Verify demands, customer commitment, connection locations, retrofit requirements, and DHS approvals.
- Preliminary Design/Engineering Feasibility - Evaluate alternative pipeline routes, collect detailed utility and traffic information, prepare updated cost estimates, and update with new information from customer development activities. Preliminary design can be initiated following initial verification of customer information, provided updated customer information does not identify other significant issues.
- Regulatory Approvals - Identify required permits and regulatory approvals, including DHS, RWQCB, CEQA, and construction permits. Develop management plan and schedule to obtain regulatory approvals, considering appropriate review periods for regulatory agencies. Regulatory activities should be initiated concurrently with preliminary design and continue through implementation and operation.
- Design/Construction - Incorporate any updated customer information, regulatory requirements, and community concerns. Reevaluate economics with updated information and design level cost estimate. Design and construction efforts can begin immediately following preliminary design.
- Training – Provide training and guidance to the site supervisors assigned by each recycled water user. Educate site supervisors on the proper use of recycled water, recycled water regulations, and basic principles of backflow prevention and cross-connection control.

13.2 Phasing Plan

WRP production is not anticipated to be adequate to meet the total demands of the system. However, as potable water demands increase and, consequently, recycled water production increases, the water available to meet system demands would also increase. Therefore, it is recommended that construction of the recycled water system be phased to utilize the increases in plant production.

Oil field produced water and treated perchlorate contaminated water would also not be available immediately, nor would they be available as permanent sources of supply. Instead, these alternative water sources will be used as interim supplies when inadequate recycled water is available from Valencia WRP. Oil field produced water is anticipated to be available as a long-term supply – approximately 20 years – and perchlorate contaminated water for only 2 to 3 years. The phasing considers when these water sources would be available.

Phasing implementation of the recycled water system is recommended for the following reasons:

- A number of the potential recycled water users are future users that do not yet need recycled water.
- The current flow of the Valencia WRP is not adequate to meet the total demands of the recycled water users.
- Capital requirements would be spread over CLWA's current planning period.
- Oil field produced water and treated perchlorate-contaminated water are not immediately available.
- Newhall Ranch is anticipated to have an initial increase in demand, peaking in 2015, then decreasing and leveling off.

The recycled water system is divided into implementation phases based primarily on service zone boundaries.

In general, the following factors should be considered in developing a phasing plan:

- Ease or willingness of customers to connect to recycled water
- Retrofit costs
- Regulatory requirements
- Community impacts and development requirements
- Water utility involvement/cooperation
- Funding availability
- Reliability and operational costs considerations
- System flexibility

The implementation phases are prioritized based on the status of the users (existing or future), the anticipated construction schedule of future users, and the proximity of the users to the non-potable water source (e.g., Valencia WRP, Placerita Oil Field, perchlorate treatment plant). It is recommended that the recycled water system be implemented as shown in Table 13-1.

The phasing sequence shown in Table 13-1 is a recommendation based on existin
and current information. Actual development of future users may necessitate modi
phasing sequence.

TABLE 13-1
IMPLEMENTATION PHASES

Phase	Zone	Year	Water Demand (AF/yr)[(a)]
1A	1430	Existing/In Progress	880
1B	1430	2003	3,862
2	1430	2003	1,236
3	1430	2004	4,644
4	1430	2005	401
5	1680	2006	658
6	1680	2007	722
7	1430	2008	3,892
8	1430	2008	171
9	1680	2009	351
10	1680	2010	227

	Total		17,441

Note: (a) Demands by phase include both existing and future demands. Not all future demands would be on-line when the phase is implemented.

Implementation phases are delineated on Figure 13-1 and described in the following sections. Recycled water users and facility requirements with preliminary capital and O&M cost estimates for each phase are summarized in Tables 13-2, 13-3, and 13-4.

13.2.1 Phase 1A complete

Phase 1A is ~~currently in progress~~ and includes the proposed Westridge Golf Course located in the vicinity of the Valencia WRP.

Based on the Reclaimed Water Master Plan prepared in 1993, CLWA has constructed ~~or is in the process of constructing~~ the Phase 1 improvements, including a 4,000 gpm recycled water pump station at the Valencia WRP, 15,600 LF of 20- and 24-inch ductile iron pipe from the Valencia WRP recycled water pump station to recycled water reservoir no. 1 (Recycled water pipeline IA-2), and recycled water reservoir no. 1, a 1.5 mg aboveground steel reservoir located near the proposed Westridge Golf Course.

Environmental documentation for Phase 1 was completed in 1991 and consisted of two primary documents:

- CLWA's "Final Program EIR for the Capital Program and Water Plan including Acquisition of Supplemental Water and Proposed Second Plant Site."
- CLWA's "Site Specific Mitigated Negative Declaration for Construction of a Reclaimed Water Distribution System."

Construction of Phase 1 improvements is anticipated to be completed in 2002.

TABLE 13-2
POTENTIAL RECYCLED WATER USERS BY PHASE

Existing Phase 1A

Notes:

1. Adds the capital cost of ASR as a function of the AF/Yr of water used ($42.63/AF-Yr.).
2. Assumes 20 year period at 6% interest rate.
3. Assumes 82% pump efficiency, 95% motor efficiency, and electricity cost of $0.12 per KWH.
4. Assumes annual parts cost to be 1% of construction costs of pumping stations, plus 0.1% of construction costs of storage reservoirs and pipelines.
5. Assumes 3 man-days per month at $40 per hour.
6. Does not include water cost
7. Capital costs for phase plus ASR portion (determined by AF used) annualized over 20 years
8. Pumping Costs for Phase plus ASR pumping costs (determined by AF used) annualized over 20 years

13.2.2 Phase 1B

Phase 1B is consistent with the phasing presented in the 1993 Reclaimed Water Master Plan, although potential additional users have been identified within the Phase 1B area. Potential recycled water users to be served as part of Phase 1B include Magic Mountain Amusement Park and proposed Magic Mountain Gold Course, as well as schools and parks in the North River and North Valencia areas. Phase 1B would also serve the proposed Suncal/Tesoro development.

Phase 1B improvements include a 3.0 mg reservoir and 29,000 LF of pipelines ranging in size from 10 to 24 inches. Phase 1B would be implemented in 2003 at an estimated total cost of $4.4 million in 2002 dollars.

13.2.3 Phase 2

Phase 2 includes a variety of recycled water uses in the existing developed area between the I-5 Freeway and the Valencia City Center. Potential users primarily include parks, schools, and homeowner's associations.

Phase 2 improvements include a 6,000 gpm expansion of the existing Valencia recycled water pump station, a 3.5 mg reservoir, and 62,000 LF of pipelines, ranging in size from 8 to 36 inches. Phase 2 would be implemented in 2003. The total cost of Phase 2 is estimated to be $10.3 million in 2002 dollars.

13.2.4 Phase 3

The largest potential user identified for Phase 3 is the proposed Newhall Ranch development. Newhall Ranch anticipates that its ultimate recycled water requirements from CLWA (Newhall Ranch would also have its own WRP) would be 3,691 AF/yr. However, its recycled water demands would increase to a peak in 2019, and subsequently level off. Other users identified as part of Phase 3 include two golf courses (one existing, one future), a park, and a school. The total projected Phase 3 demand is 4,644 AF/yr.

Planned improvements for Phase 3 include more than 50,000 LF of pipeline, ranging from 8 to 24 inches, a new 3.0 mg reservoir, and expansion of the Valencia WRP pump station to 12,000 gpm. Newhall Ranch plans to develop their own daily storage facilities within their boundaries. Recycled water would be delivered to Newhall Ranch at three connection points. Phase 3 would be implemented in 2004. The total cost of Phase 3 is estimated to be $8.8 million in 2002 dollars.

13.2.5 Phase 4

Phase 4 proposes to provide recycled water to a mix of existing and planned users in the Civic Center and Porta Bella areas. Potential users include schools, playing fields, commercial and office park landscaping, and the civic center itself. A total demand of 401 AF/yr has been identified.

Planned improvements for Phase 4 include almost 30,000 LF of 8-, 20- and 36-inch pipeline and a new 3.5 mg reservoir. The total cost of Phase 4 is estimated to be $12.4 million in 2002 dollars. Phase 4 is planned to be implemented in 2005.

13.2.6 Phase 5

Phase 5 would serve a variety of existing and planned users in the north-central part of the CLWA service area, including the "panhandle" area. Potential users include schools, commercial development, parks, a golf course, and City of Santa Clarita landscape management districts.

Phase 5 would be implemented in 2006, with 8,800 LF of pipeline ranging from 8 to 24 inches. The total cost of Phase 5 is estimated to be $1.7 million in 2002 dollars.

13.2.7 Phase 6

Phase 6 would serve a variety of existing and planned users in the North Valencia area, including schools, parks, and a golf course. Phase 6 would be implemented in 2007. Improvements for Phase 6 include 29,000 LF of pipeline ranging from 8 to 36 inches and a 3.5 MG reservoir. The total cost of Phase 6 is estimated to be $4.6 million in 2002 dollars.

13.2.8 Phase 7

In 2008, the Placerita Canyon Oil Field Produced Water Treatment Facility is projected to come on-line. This new source of recycled water would help serve Phase 7, which includes a mix of existing and planned users in the southern part of the CLWA service area near the 14 Freeway and the Placerita Canyon Oil Field. Potential users include schools, parks, homeowners' associations, and commercial development at Golden Valley Ranch.

Phase 7 improvements include a pump station for the 1,250-gpm oil field produced water treatment facility, a 3.25 mg reservoir, and 31,800 LF of pipeline ranging from 8 to 36 inches. The total cost of Phase 7 is estimated to be $9.0 million in 2002 dollars.

13.2.9 Phase 8

Phase 8 primarily includes future users in the Porta Bella development, which would be completed by Phase 8 implementation in 2008. Phase 8 improvements include 18,000 LF of pipeline ranging from 8 to 36 inches, and the modification of Honby pump station to provide 5,000 gpm of booster pumping capacity. The total cost of Phase 6 is estimated to be $5.3 million in 2002 dollars.

13.2.10 Phase 9

Phase 9 includes schools, parks, and landscaping in the Canyon Country area toward the eastern end of the CLWA service area. Proposed Improvements include 7,000 LF of 8- to 24-inch pipeline and one 3.25 MG reservoir. Phase 9 would be implemented in 2009. The total cost of Phase 9 is estimated to be $1.8 million.

13.2.11 Phase 10

Phase 10 includes parks, schools, a golf course, and several landscape maintenance districts for a total demand of 227 AF/yr. Improvements for Phase 10 include 18,000 LF of 14-inch pipe, with a total estimated cost of $1.7 million in 2002 dollars. Phase 10 would be implemented in 2010.

13.2.12 Phase 11

Phase 11 would serve users such as the Circle J and portions of the Porta Bella area. Phase 11 improvements include 9,100 LF of 10-inch PVC pipe for a total estimated cost of $0.7 million. Phase 11 would be implemented in 2011.

13.3 Implementation Schedule

To encourage the development of recycled water systems within new development, a 10-year implementation schedule is recommended. Under the Water Recycling in Landscaping Act (SB 2095, Johnson), once a recycled water producer determines that they will produce recycled water within the boundaries of a local agency, the local agency is required to adopt and enforce a recycled water ordinance. The ordinance must condition new development to utilize recycled water for landscaping purposes.

Implementation of ~~the~~ eleven recycled water phases described previously would occur from the present through 2011. The implementation schedule is presented in Figure 13-2.

2014

List of Figures and Tables

I. Introduction and Background

Perchlorate has been a water quality concern in the Santa Clarita Valley since 1997 when it was originally detected in four Saugus wells operated by the municipal water purveyors in the eastern part of the Saugus Formation, near the former Whittaker-Bermite facility. In late 2002, perchlorate was detected in a fifth municipal well, in this case an Alluvial well also located near the former Whittaker-Bermite site. The five perchlorate-impacted wells have been removed from active water supply service.

At present, perchlorate is not a regulated chemical in drinking water. However, the state Department of Health Services (DHS) requires that water utilities test their water sources for certain unregulated chemicals, and perchlorate is one of those chemicals. The DHS "notification level" for perchlorate is 6 micrograms per liter (ug/l).[1] DHS currently anticipates proposing a Maximum Contaminant Level (MCL) for perchlorate in 2005.

Since the detection of perchlorate and resultant inactivation of impacted wells, the Purveyors have been conducting regular monitoring of active wells near the Whittaker-Bermite site. In late March 2005, that monitoring detected the presence of perchlorate in Valencia Water Company's Well Q2, an alluvial well located immediately northwest of the confluence of Bouquet Creek and the Santa Clara River (Figure I-1). The initial detection of perchlorate was at a concentration of 11 ug/l; two confirmation samples in the first two weeks of April detected perchlorate at concentrations of 9.8 and 10 ug/l, respectively. As a result of the detection and confirmation of perchlorate in its Well Q2, Valencia has removed the well from active service and is pursuing rapid permitting and installation of wellhead treatment, as described herein, in order to return the well to water supply service.

For several years prior to the recent detection of perchlorate in Valencia's Well Q2, the water Purveyors have recognized that, among other aspects of an overall remediation program, such a program would most likely include an element of pumping from impacted wells, or from other wells in the immediate area, to establish hydraulic conditions that would control the migration of contamination from further impacting the aquifer in a downgradient (westerly) direction. The overall program would also include the installation of treatment to allow the restored pumping capacity to be used for municipal supply. In cooperation with state regulatory agencies and

[1] "Notification level" means the concentration level of a contaminant in drinking water delivered for human consumption that DHS has determined, based on available specific information, does not pose a significant health risk but warrants notification pursuant to applicable law. Notification levels are nonregulatory, health-based advisory levels established by DHS for contaminants in drinking water for which maximum contaminant levels have not been established. Notification levels are established as precautionary measures for contaminants that may be considered candidates for establishment of maximum contaminant levels, but have not yet undergone or completed the regulatory standard setting process prescribed for the development of maximum contaminant levels. Notification levels are not drinking water standards.

CH2MHILL

RDD \\ODIN\PROJ2\55\SANTACLARITA_MOU\FIGURES\MXD\042205\FIG01.MXD FIG01.PDF 04/22/2005 investigators working for Whittaker-Bermite, Castaic Lake Water Agency (CLWA) and the Purveyors, including Valencia Water Company, have developed an off-site plan that will include installation of water treatment facilities to remove perchlorate and restore operation of two of the initially impacted Saugus wells through that treatment process. The operation of those two wells with treatment, scheduled to be in service in 2006, will hydraulically contain the perchlorate contamination moving from the former Whittaker-Bermite site and protect downgradient non-impacted wells. It will also restore the annual volumes of water that were pumped from the impacted wells before they were inactivated. In concert with the installation of treatment and the return of certain impacted wells to active water supply service, the balance of total pumping capacity from the impacted wells will be restored by constructing replacement wells in a non-impacted portion of the basin west of Interstate 5.

The development of the control and restoration plan for the initially impacted wells included consideration that it should fit within the larger scale of on-site and possibly other off-site remediation activities. While such activities did not specifically anticipate the treatment of VWC's Well Q2 as described herein, utilization of the same treatment methodology and operation of the well to contain perchlorate from contamination of downgradient wells, are consistent with currently planned and other potential on-site and off-site remediation activities.

II. Impact of Water Supply

As a result of the recent detection of perchlorate, Valencia Water Company has removed Well Q2 from active water supply service until it can install wellhead treatment for perchlorate removal, as described herein, such that the well can be returned to service. Although it is expected that the permitting and installation of wellhead treatment can be accomplished by mid-summer, in advance of the peak water demand season, it is appropriate to assess the impact of the removal of Well Q2 on the overall adequacy of Valencia's water supply until such treatment is in place and the well is returned as part of Valencia's total water supply.

The overall adequacy of water supply derives from three considerations: 1) sufficient source capacity (wells and pumps, plus other sources such as, in this case, connections to CLWA's treated surface water distribution system); 2) sustainability of the groundwater resource to meet the demand of Valencia and other pumpers in the basin on a renewable basis; and 3) protection of groundwater sources (wells) from known contamination, or provisions for treatment in the event of contamination. All three considerations are discussed in the following sections.

Adequacy of Source Capacity

The temporary removal of Well Q2 from active service represents a reduction of 1,200 gpm of source capacity. After that removal, Valencia still has a total of 19 active operational wells, 14 wells completed in the Alluvial aquifer and 5 wells completed in the Saugus Formation. The combined pumping capacities of the 14 Alluvial wells is slightly more than 20,000 gpm, and the combined pumping capacities of the 5 Saugus wells is slightly more than 10,000 gpm. The individual pumping capacity of each Valencia well is listed in Table II-1.

In addition to its water supply wells, Valencia has six connections to CLWA's system that distributes treated surface water from the State Water Project to the various municipal purveyors in the Valley. The combined capacity of those four connections (Turnouts V2, V4, V5, V6, V7 and V8) is 26,500 gpm. The individual capacity of each CLWA turnout connection to the Valencia distribution system is listed in Table II-2.

The combined source capacity of Valencia's active wells, after temporary inactivation of Well Q2, and its CLWA turnouts is thus a total of about 57,000 gpm.

As part of recent review of its overall water supply, Valencia examined its maximum day demand in the last year, 2004. The maximum day demand occurred in July, when the largest historical single day demand of 143.3 acre-feet was experienced. That volumetric demand equates to an average flow on that day of nearly 32,500 gpm.

Table II-1
Active Groundwater Source Capacity
Valencia Water Company

Well	Pump Capacity (gpm)	Maximum Annual Capacity (af)	Normal Year Production[1] (af)	Dry Year Production[1] (af)
Alluvium				
Well D	1,050	1,690	690	690
Well N	1,250	2,010	620	620
Well N7	2,500	4,030	1,160	1,160

Table II-2
Turnout Connections to CLWA Treated Water Distribution
Valencia Water Company

Station Number	Number of Pumps and Total Horsepower	Capacity (gpm)
V2	Pressure Regulating Station	3,000
V4	3 – 195	4,500
V5	3 – 155	4,500
V6	2 – 25	1,500
V7	Pressure Regulating Station	5,000
V8	3 – 300	8,000
	Total	**26,500**

In accordance with the provisions of the Waterworks Standards in the California Health and Safety Code, and also in accordance with the provisions of the State Public Water Commission, the source capacity of a municipal water purveyor should be adequate to meet maximum day demand. Generally accepted engineering practice adds a factor of safety to those minimum requirements to account for possible outages of one or more supply sources during a period of maximum day demand. With total source capacity of about 57,000 gpm, after temporary deactivation of Well Q2, Valencia has sufficient source capacity to meet its maximum day demand of 32,500 gpm with allowance for potential outage of one or more individual sources (wells) or treated surface water connections. As a result, the temporary deactivation of Well Q2 does not adversely impact Valencia's ability to meet existing demands; in fact, Valencia has sufficient surplus source capacity to meet future increases in maximum day demand with existing sources, to be increased by returning Q2 to service after installation of treatment as described herein.

Sustainability of Groundwater

In contrast to assessing the adequacy of Valencia's source capacity by examining the total capacity of its water sources and comparing it to Valencia's maximum day demand, the sustainability of groundwater resources in the Valley is more appropriately assessed by examining the response of the groundwater basin to the collective pumping demands placed on it for municipal and ongoing agricultural water supply. Until recently, the long-term renewability of Alluvial groundwater was empirically determined from approximately 60 years of recorded experience: long-term stability in groundwater levels and storage, with some dry period fluctuations in the eastern part of the basin, over a historical range of Alluvial pumpage from as low as about 20,000 afy to as high as about 43,000 afy. The long-term sustainability of Saugus groundwater was empirically determined from a more historical record that shows fairly low annual pumping in most years, with one four-year period of increased pumping up to about 15,000 afy, that produced no long-term depletion of the substantial groundwater storage in the Saugus. Those empirical observations in both the Alluvium and the Saugus Formation have now been complemented by the development and application of a numerical groundwater flow model, which has been used to predict aquifer response to the planned operating ranges of pumping from both aquifers for both municipal and agricultural water supply. The numerical groundwater flow model has also been used to analyze the control of contaminant migration under selected pumping conditions that would restore, with treatment, pumping capacity that has been inactivated due to perchlorate contamination detected in some wells in the basin as described herein.

To examine the yield of the Alluvium or, in other words, the sustainability of Alluvium on a renewable basis, the groundwater flow model was used to examine long-term projected response of the aquifer to pumping for municipal and agricultural uses in the 30,000 to 40,000 afy range under average/normal and wet conditions, and in the 30,000 to 35,000 afy range under locally dry conditions. To examine the response of the entire aquifer system, the model also incorporated pumping from the Saugus Formation in accordance with the normal (7,500-15,000 afy) and dry year (15,000-35,000 afy) operating plan for that aquifer. The preceding ranges of pumping from the two aquifer systems, commonly known locally as the operating plan for groundwater supply, are described in detail in the Amended 2000 Urban Water Management Plan prepared by CLWA and the municipal Purveyors in the Valley. The model was run over a 78 year hydrologic period which was selected from actual historical hydrology (i.e., precipitation) to examine a number of hydrologic conditions that would be expected to affect both groundwater pumping and groundwater recharge. The selected 78 year simulation period was assembled from an assumed recurrence of 1980 to 2003 hydrologic conditions, followed by an assumed recurrence of 1950 to 2003 hydrologic conditions. The 78 year period was analyzed to define both local hydrologic conditions (normal vs. dry), which affect the rate of pumping from the Alluvium, and hydrologic conditions that affect State Water Project operations, which in turn affect the rate of pumping from the Saugus.

The resultant pumping cycles are summarized as follows:

- Twenty-four years of dry year Alluvial pumping at 30,000 to 35,000 afy,

- One drought of four consecutive dry years of Alluvial pumping at 30,000 to 35,000 afy,
- Two droughts of three consecutive dry years each, with Alluvial pumping at 30,000 to 35,000 afy,
- Three selected years with assigned dry-year Alluvial pumping despite near-normal or above-normal rainfall because each selected year was preceded by a multi-year drought,
- Eighteen years of dry-year pumping from the Saugus, or an average of one dry year approximately every four years,
- Two droughts lasting three years, plus (in both cases) a dry year that occurs two years before the beginning of each three-year drought and another dry year that begins one year after each three-year drought has ended; Saugus pumping increased into the 15,000 to 35,000 afy range in all those years,
- Two droughts lasting two years; Saugus pumping increased into the 15,000 to 25,000 afy range in those years,
- Sixty years of normal-year Saugus pumping, 7,500 to 15,000 afy.

The preceding ranges of Saugus pumping included the planned restoration of recent historic pumping from the perchlorate-impacted wells. That pumping was analyzed to assess, in addition to the overall recharge of the Saugus, the effectiveness of controlling the migration of perchlorate by extracting and treating contaminated water close to the source of contamination.

Simulated Alluvial aquifer response to the preceding range of hydrologic conditions and pumping stresses was essentially a long-term repeat of the historical conditions that have resulted from similar pumping over the last several decades. The resultant response consisted of: 1) generally constant groundwater levels in the middle to western portion of the Alluvium, and fluctuating groundwater levels in the eastern portion of the Alluvium as a function of wet and dry hydrologic conditions, 2) variations in recharge that directly correlate with wet and dry hydrologic conditions, and 3) no long-term decline in groundwater levels or storage. Based on the combination of actual experience with Alluvial aquifer pumping at capacities similar to those planned for the future and the resultant sustainability (recharge) of groundwater levels and storage, complemented by modeled projections of aquifer response to planned pumping rates that also show no depletion of groundwater, the Alluvial aquifer can be considered a sustainable water supply source to meet the Alluvial portion of the operating plan for the groundwater basin.

Simulated Saugus Formation response to the ranges of pumping under assumed recurrent historical hydrologic conditions was consistent with actual experience under smaller pumping rates. The response consisted of: 1) short-term declines in groundwater levels and storage near pumped wells during dry-period pumping, 2) rapid recovery of groundwater levels and storage after cessation of dry-period pumping, and 3) no long-term decreases or depletion of groundwater levels or storage. The combination of actual experience with Saugus pumping and recharge up to about 15,000 afy, now complemented by modeled projections of aquifer response that show long-term utility of the Saugus at 7,500 to 15,000 afy in normal years and rapid recovery from higher pumping rates during intermittent dry periods, shows that the Saugus Formation can be considered a sustainable water supply source to meet the Saugus portion of the operating plan for the groundwater basin.

Protection of Other Sources (Wells)

Some detail of the overall perchlorate contamination issue, which has had a larger impact on the Saugus Formation than on the Alluvium, is included in **Status of Saugus Restoration and Containment** below. As detailed in that section, there has been extensive investigation of the extent of perchlorate contamination which, in combination with the groundwater modeling described above, has led to the current plan for integrated control of contamination migration and restoration of impacted pumping (well) capacity by 2006. While most of the perchlorate control and restoration plan is focused on the Saugus Formation, part of that plan includes induced capture of potentially contaminated groundwater in the Alluvium by pumping of selected Saugus wells. Specific long-term resolution of perchlorate contamination in the Alluvium, which had previously impacted just one water supply well, is currently expected to focus on source control through on-site treatment in the northern Alluvium (at the north of the former Whittaker-Bermite site) and subsequent restoration of the contaminated Stadium Well. In the interim, the questions are how the recently impacted Well Q2 will be resolved, and whether other active Alluvial wells could be contaminated and, if so, what effect that might have on the adequacy of Alluvial groundwater supplies.

Until the recent detection of perchlorate in Valencia's Well Q2, ongoing monitoring of all active municipal wells near the Whittaker-Bermite site had shown no detections of perchlorate in any active Alluvial wells. However, based on a combination of proximity to the Whittaker-Bermite site and prevailing groundwater flow directions, there was logical concern that perchlorate could contaminate nearby, downgradient Alluvial wells, and, as a result, there have been provisions in place to respond to perchlorate contamination if it should occur. The groundwater model was used to examine capture zones around Alluvial wells under planned operating conditions (pumping capacities and volumes) for the time period through currently scheduled restoration of impacted contaminated wells by 2006. That capture zone analysis of Alluvial wells generally near the Whittaker-Bermite site suggested that inflow to those wells would either be upgradient of the contamination site, or would be from the Alluvium beyond where perchlorate is most likely to be transported.

At the time of the preceding analysis, a noted possible exception to its conclusions involved Valencia Water Company's Pardee wellfield, which includes its Wells N, N7, and N8. Although the capture zone analysis did not show the Pardee wells to be impacted, they were considered to be at some potential risk due to the proximity of their capture zone to the Whittaker-Bermite site. Other nearby Alluvial wells, including Valencia's Well Q2, were considered to be at lesser risk due to their distances from the site, orientation to groundwater flow near the site, and other factors such as the presence of the Santa Clara River between the wells and the Whittaker-Bermite site.

With recognition that potentially at-risk wells such as Valencia's Pardee wellfield could be readily replaced on an interim basis by utilizing some of the surplus capacity among all the other Alluvial wells, Valencia has planned for some time that, if the Pardee wells were impacted by perchlorate contamination, it has made site provisions at those wells for installation of wellhead treatment. Such treatment would be the same methodology as planned for long-term treatment of the contaminated Saugus wells. With treatment installed, Valencia would retain the wells in service for the same objectives as planned for restoring impacted Saugus pumping capacity by extracting contaminated water, treating it for beneficial (drinking water) use, and controlling local groundwater flow to protect further downgradient wells. The response to perchlorate detection in Well Q2 is identical to what was envisioned in the event of contamination at the Pardee wells.

III. Response Plan for Well Q2

As described in the status discussion below, one of the completed tasks in the overall response to perchlorate contamination of four Saugus wells has been the evaluation of alternative treatment methodologies and the selection of ion exchange for removal of perchlorate from water to be pumped from the two impacted wells that will be used for a combination of containment and capture of perchlorate contamination. As a result of that completed work, Valencia was in a position to immediately respond to the confirmed detection of perchlorate in Well Q2 by opening contract discussions with a selected contractor who can furnish, install and operate the same ion exchange treatment methodology which has been selected for the impacted Saugus wells.

In light of the preceding, after detection of perchlorate in its Well Q2, Valencia contacted USFilter to prepare a complete turnkey service contract to install and maintain treatment facilities capable of removing perchlorate pumped from the well to a non-detectable level. USFilter would cover all major components and estimate of installation materials and labor for start-up. The specific Q2 treatment system will incorporate USFilter HP1220HF ion exchange pressure vessels operating in a lead/lag configuration. The vessels are 12 feet in diameter and each will contain a selective resin designed to remove perchlorate. There is no waste brine generated from this treatment system. If resign replacement is necessary, USFilter will remove the resin from the treatment system and destroy it by incineration at an approved waste site.

Well Q2 is located along Bouquet Canyon Road adjacent to the Rio Vista Pump Station owned by CLWA. The treatment system will be located on the existing well site property which is owned by Valencia or, if necessary, use a small portion of land owned by CLWA. Valencia is preparing a site plan that will require constructing a concrete foundation for the ion exchange pressure vessels and other ancillary equipment and controls required to integrate the treatment system into its water supply operations.

Installing wellhead treatment at Well Q2 will require review and approval by the California Department of Health Services (DHS). Valencia will prepare and submit an application to amend Valencia's water supply permit allowing wellhead treatment at Well Q2. DHS approval is expected since ion exchange technology is recognized by DHS as "best available technology" for perchlorate removal, and multiple ion exchange treatment systems have been approved and permitted by DHS for drinking water systems. Also, the Department of Toxic Substances Control (DTSC) will include this project as part of the interim actions required to address perchlorate contamination in the Northern Alluvium. Their review was contemplated under the existing Environmental Oversight Agreement between the water purveyors and DTSC.

Since Valencia is able to rapidly respond to the contamination of its Well Q2 by installation of site modifications and turnkey contracting for treatment equipment, it intends to cooperatively pursue the amended water supply permit so it can return the well to service as soon as possible.

IV. Protection Plan for Non-Impacted Wells

As noted above, based on a combination of proximity to the Whittaker-Bermite site and prevailing groundwater flow directions, there is a logical concern that perchlorate could impact nearby downgradient Alluvial wells, the closest of which are owned and operated by Valencia. As part of assessing their overall groundwater supply during the period before the impacted Saugus wells are restored in 2006, the Purveyors commissioned the use of the groundwater flow model to examine capture zones around nearby Alluvial wells under planned pumping operations through that time period. The results of that work, as reported in the CH2M Hill Technical Memorandum "*Analysis of Near-Term Groundwater Capture Areas for Production Wells Located Near the Whittaker-Bermite Property*" (Santa Clarita, California), suggested that inflow to the nearby Alluvial wells would either be upgradient of the contamination site, or would be from the Alluvium beyond where perchlorate is most likely to be transported. However, again due primarily to proximity, in this case between the capture zones and the Whittaker-Bermite site, the nearest Valencia Pardee wellfield (Wells N, N7 and N8) was considered to be at some potential risk because perchlorate had been detected in nearby Alluvial monitoring wells that were installed as part of a federally funded investigation of the extent and nature of contamination by the Army Corps of Engineers. As previously described, the other nearby Alluvial wells, including Valencia's Well Q2, were considered to be at lesser risk. Ultimately, irrespective of model simulations or other considerations, Valencia has responsibilities to supply both adequate and safe municipal water and, as a result, is prepared to respond to impacts at any of its nearby Alluvial wells in a similar manner as described for Well Q2 herein.

Thus, the response by Valencia to any future well impacted by perchlorate contamination will be to install wellhead treatment as soon as practicable, thereby ensuring adequate supplies of high quality water to its customers. Toward that end, Valencia has already dedicated space at each of the nearest well sites for addition of wellhead treatment facilities, as will be installed at Well Q2, if necessary. This short-term response plan complements the longer term actions being taken by the property owner under supervision of DTSC. For example, studies conducted by consultants under contract with the property owner have completed successful testing of in-situ groundwater remediation of perchlorate. It is anticipated this program along with several other measures approved by DTSC will be implemented over time to contain and remove perchlorate from the Northern Alluvium. Once this is accomplished, the detection of perchlorate in the Northern Alluvium is expected to decline below detectable levels over time. Successful groundwater remediation will ultimately result in the removal of wellhead treatment at wells no longer impacted by perchlorate contamination.

V. Status of Saugus Restoration and Containment

From the outset of dealing with the detection of perchlorate in the four Saugus wells in 1997, the Purveyors have recognized that, among other aspects of an overall remediation programs, such a program would most likely include an element of pumping from impacted wells, or from other wells in the immediate area, to establish hydraulic conditions that would control the migration of contamination from further impacting the aquifer in a downgradient (westerly) direction. Thus, the Purveyors expected that, as the regulatory process moved forward, the overall perchlorate remediation program could include dedicated pumping from some or all of their impacted wells, with appropriate treatment, such that two desirable objectives could both be achieved: control of subsurface flow and protection of downgradient wells, and restoration of some or all impacted water supply. Not all impacted capacity is required, however, for control of groundwater flow. As a result, the remaining capacity would be replaced by construction of replacement wells at other non-impacted locations.

In cooperation with state regulatory agencies and investigators working for Whittaker-Bermite, CLWA and the water Purveyors in the Santa Clarita Valley have developed an off-site plan that focuses on the above concepts of groundwater flow control and restored pumping capacity, and also fits within the larger scale of on-site and possibly other off-site remediation activities. As specifically relates to water supply, the plan includes the following:

- constructing and operating a water treatment process that removes perchlorate from two contaminated wells such that the produced water can be used for municipal supply,

- hydraulically containing the perchlorate contamination moving from the Whittaker-Bermite site toward the impacted wells by pumping the wells at rates that will capture water from all directions around them,

- protecting the downgradient non-impacted wells via the same hydraulic containment that results from pumping two of the contaminated wells,

- restoring the annual volumes of water that were pumped from the impacted wells before they were inactivated, and also restoring the wells' total capacity to produce water in a manner consistent with the Purveyor's operational plan for groundwater supply.

The schedule for implementation of the plan to restore the initially impacted wells is that permitting, design and construction is to be complete by 2006.

Returning any of the contaminated wells to municipal water supply service by installing treatment requires issuance of a permit from DHS before the water can be considered potable and safe for delivery to consumers. The permit requirements, contained in DHS Policy Memo 97-005 for direct domestic use of impaired water sources, include formal studies and engineering work to demonstrate that pumping these wells and treating the water will be protective of public health for users of the water. The policy memo requires that DHS review the water purveyor's plan, establish appropriate permit conditions for the wells and treatment system, and provide overall approval of returning the contaminated wells to service for potable use. Ultimately, the Purveyor's plan and the DHS requirements are intended to ensure that the water introduced to the potable water distribution system has no detectable concentration of perchlorate.

As part of the formal permitting for use of impacted wells with treatment, DHS Policy 97-005 requires an analysis to demonstrate contaminant capture and protection of other nearby water supply wells. The development and calibration of a numerical groundwater flow model of the entire basin was initiated as a result of a 2001 Memorandum of Understanding among the Upper Basin Water Purveyors (CLWA, CLWA Santa Clarita Water Division, Los Angeles County Waterworks District 36, and Valencia Water Company) and the United Water Conservation District in Ventura County. Although the groundwater model was initially intended for use in analyzing the yield and sustainability of groundwater in the basin, it was adaptable to analyze both the sustainability of groundwater under an operational scenario that included the full restoration of perchlorate-impacted supply, and the containment of perchlorate near the Whittaker-Bermite property (i.e. by pumping some of the impacted wells), including preventing the movement of perchlorate contamination to other portions of the aquifer system. DTSC reviewed and approved the construction and calibration of the regional model as described in the final model report "*Regional Groundwater Flow Model for the Santa Clarita Valley, Model Development and Calibration*" (CH2M Hill, April, 2004).

After DTSC approval of the model, it was used to simulate the capture and control of perchlorate via restoration of contaminated wells, with treatment, as described above. The results of that work are summarized in a second report "*Analysis of Perchlorate Containment in Groundwater Near the Whittaker-Bermite Property, Santa Clarita, California*" (CH2M Hill, September 2004). The modeling analysis indicated that the pumping of contaminated wells SCWC-Saugus1 and SCWC-Saugus2 at rates of 1,200 gpm each on a nearly continual basis will effectively contain perchlorate migrating westward in the Saugus Formation from the Whittaker-Bermite property. The analysis also indicated that 1) no new production wells are needed in the Saugus Formation to meet the perchlorate containment objective, 2) impacted well NCWD-11 is not a required component of the containment program, and 3) the use of other water supplies in lieu of pumping at SCWC-Saugus1 and SCWC-Saugus2 would likely be detrimental to the long-term quality of groundwater in the Saugus Formation because pumping at SCWC-Saugus1 and SCWC-Saugus2 is necessary to prevent migration of perchlorate to other portions of the Saugus Formation.

The perchlorate containment report also includes the general design of a sentinel groundwater monitoring network and program required by DHS as part of its 97-005 permitting. The perchlorate containment report was approved by DTSC in November 2004. With that approval, the model is now being used to support the source water assessment and the balance of the permitting process required by DHS under is 97-005 policy.

A detailed history of the perchlorate issue and its impact on municipal water supply in the Valley is included in the Amended 2000 Urban Water Management Plan for the Valley. Included in that history are discussions of the detection of perchlorate in municipal supply wells, investigation and oversight by regulatory agencies, federally funded investigation of the extent and nature of contamination, litigation by the affected Purveyors, and cooperative settlement work toward selection and implementation of solutions that will restore impacted municipal groundwater supply and control the migration of perchlorate, the latter to protect downgradient wells. As noted above, the overall schedule for installation of treatment and return of impacted wells to service has been that those facilities be operational by 2006. The most current status of overall work toward that schedule was prepared in early April 2005. As of that date, the treatment and well reoperation project description has been finalized, and final settlement discussions were proceeding between the Purveyors and the Whittaker-Bermite parties. A draft Remedial Action Plan (RAP) has been completed; finalization of the RAP is pending determination of requirements by DTSC. A final report on the federally funded conceptual hydrogeology investigation prepared by the Army Corps of Engineers was completed in January 2005; funding is in place for limited monitoring of existing test wells in the next fiscal year. Draft reports on Source Water Assessment, Water Quality Investigation, and Source Protection Plan, all part of the DHS 97-005 approval process, are complete and in review. Draft reports on Effective Monitoring and Treatment, Human Health Risk, and Alternatives Evaluation are scheduled for completion in early May and June, respectively. CEQA review is scheduled for completion by the first of July. In the general area of design and construction, pipeline alignment studies have been completed, and work is continuing on final treatment process selection. The start of construction is scheduled for October 2005, with startup of the restored wells and new treatment facilities scheduled for February 2006. Thus, the descriptions of planned perchlorate containment, restoration of impacted wells, and adequacy of water supply in the interim remain as detailed in the Amended 2000 Urban Water Management Plan. The response plan for Valencia’s Well Q2, as detailed herein, is consistent with maintaining the planned volumes and distribution of Alluvial pumping that are part of the overall restoration of perchlorate-impacted groundwater supply in the Valley.

I. Introduction

Castaic Lake Water Agency

Castaic Lake Water Agency (CLWA) was formed in 1962 as a State Water Project Contractor to provide wholesale water supply from the State Water Project (SWP) to retail water purveyors in the Upper Santa Clara River area, most notably to Newhall County Water District, Los Angeles County Waterworks District No. 36, Santa Clarita Water Company and Valencia Water Company. In 2001, as part of legislation authorizing CLWA to provide retail water service to individual municipal customers in addition to its ongoing wholesale water supply, Assembly Bill 134 included a requirement that CLWA prepare a groundwater management plan in accordance with the provisions of Water Code Section 10750 et seq., which was originally enacted by, and is commonly known as, Assembly Bill 3030. This groundwater management plan has been prepared to satisfy the requirements of AB 134 and to both complement and formalize a number of existing water supply and water resource planning and management activities in the CLWA service area.

The CLWA service area encompasses all of the existing and currently planned municipal water service areas of the Upper Santa Clara River area, i.e. the suburban areas generally proximate to the Santa Clara River in Los Angeles County, generally between hills of the San Gabriel Mountains and the Santa Susana Mountains on the north and south, and between the Los Angeles/Ventura County line and Lang Station on the west and east, respectively. The extent of the CLWA service area and the geographical locations of the individual water purveyors within the CLWA service area are illustrated in Figure 1-1.

Santa Clara River Valley Groundwater Basin, East Subbasin

The groundwater basin generally beneath the CLWA service area, identified in DWR Bulletin 118 as the Santa Clara River Valley Groundwater Basin, East Subbasin (Basin No. 4-4.07), is comprised of two aquifer systems, the Alluvium generally underlying the Santa Clara River and its several tributaries, and the Saugus Formation which underlies much of the entire Upper Santa Clara River area. The mapped extent of the Santa Clara River Valley East Subbasin in Bulletin 118, which is approximately the outer extent of the Alluvium and the Saugus Formation, and its

CLWA and Purveyors` Service Areas

relationship to the extent of the CLWA service area are illustrated in Figure 1-2.

The two aquifer systems that comprise the groundwater basin are described in detail in this plan. For purposes of this plan, the groundwater basin is encompassed by the CLWA service area, and CLWA is the logical public water supply agency to prepare and implement a groundwater management plan for the Santa Clara River Valley East groundwater subbasin.

Overview of Water Requirements and Supplies

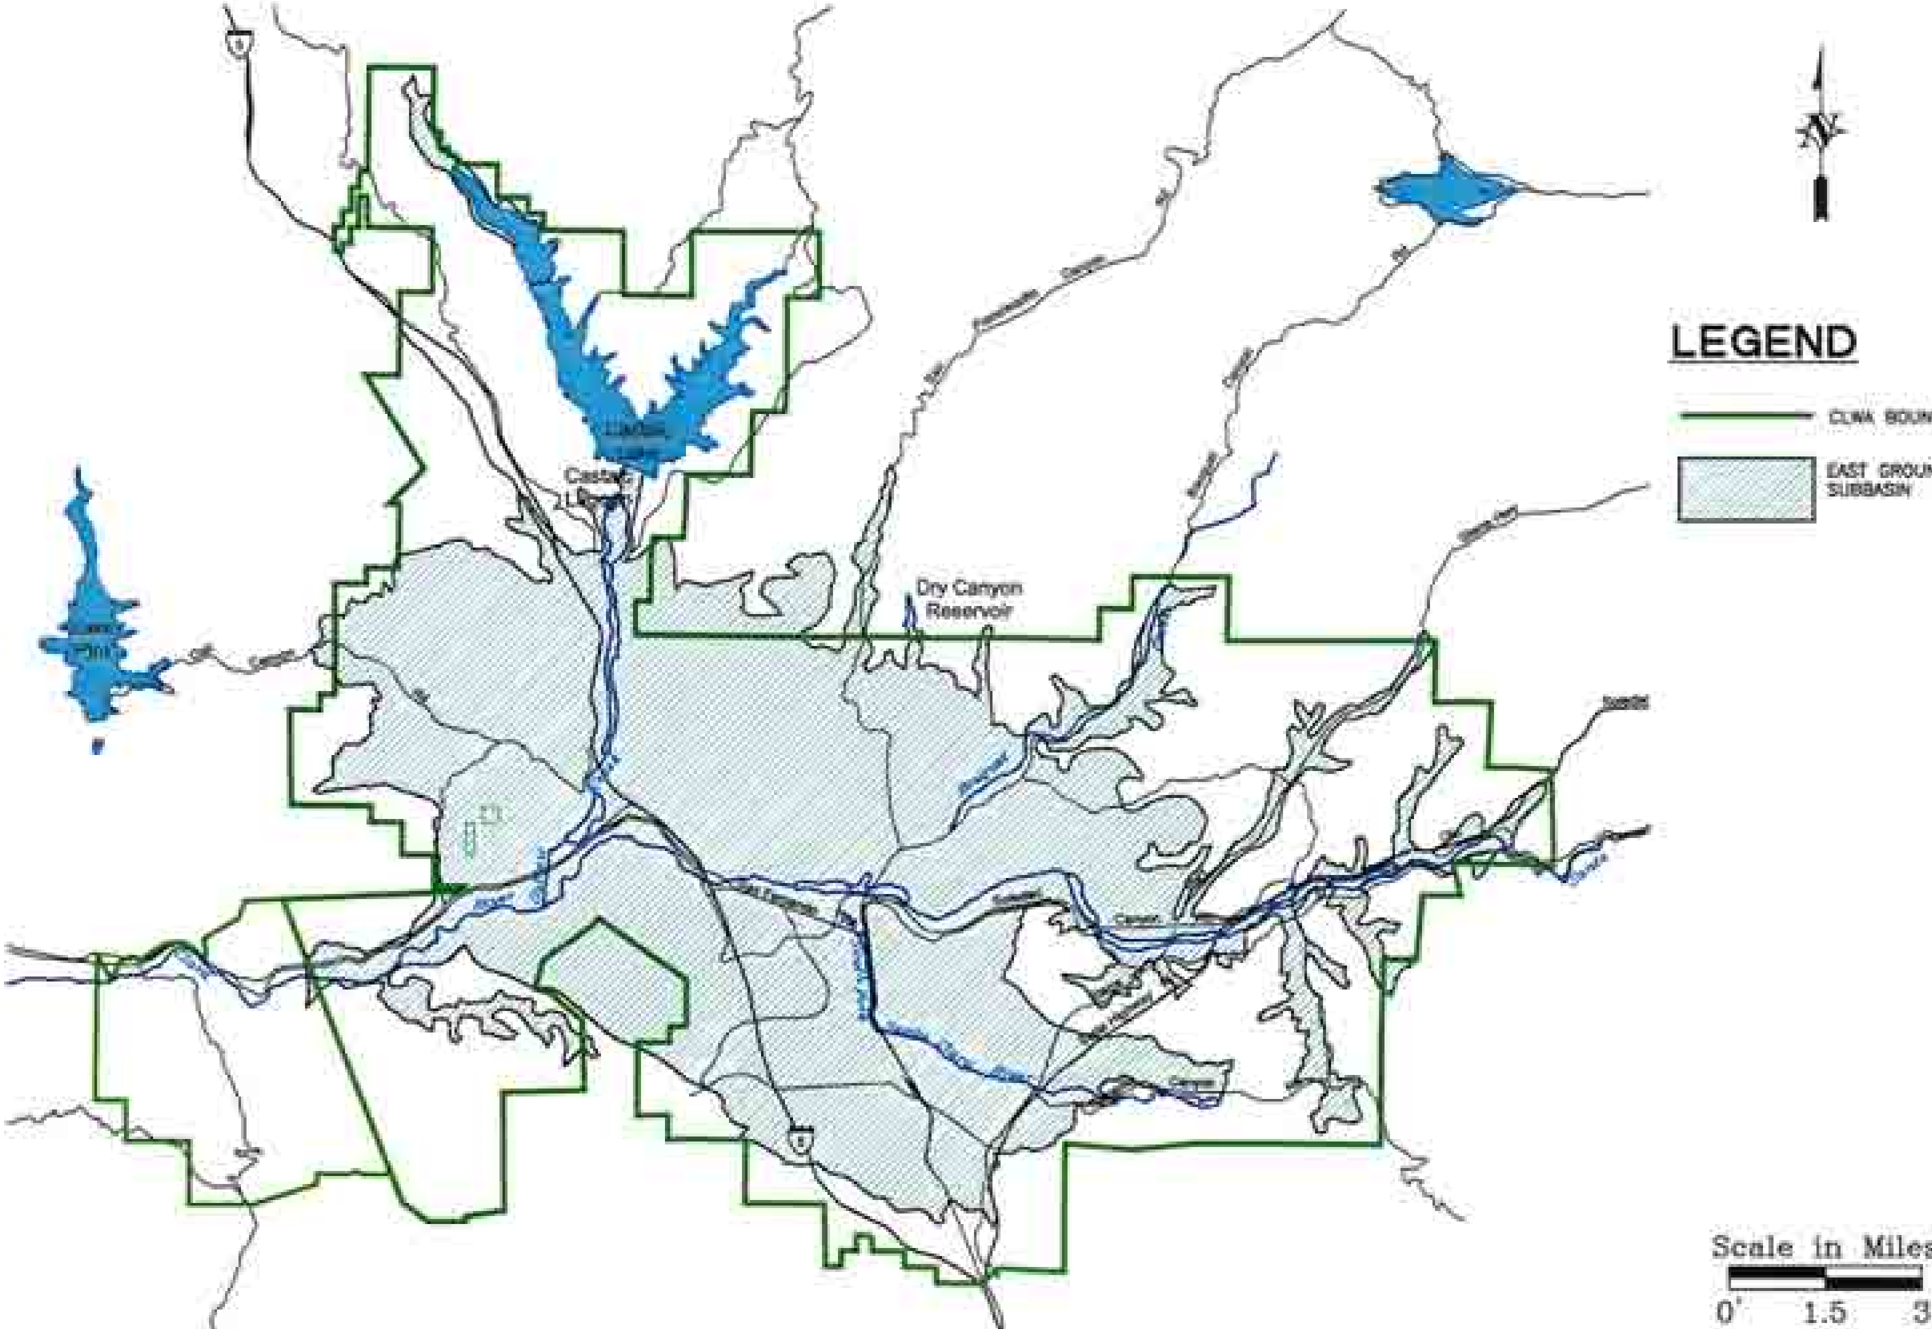
Historically, while development of local water supplies dates back at least 100 years, the earliest complete records of water use in the basin date from the late 1940's, when practically all water demand was for agricultural use. From that time through the early 1960's, agricultural water use, which was solely supplied by local groundwater, ranged from about 27,000 to about 42,000 acre-feet per year (afy). Over the succeeding three decades, agricultural water use progressively declined, into the range of about 8,000 to 10,000 afy, followed by a slight increase into the range of about 12,000 to 15,000 afy over the last ten years. Current projections are for agricultural water use to substantially decline, to about 7,000 afy, over the next 20 years.

Significant municipal water use in the basin did not begin until the early 1960's, when municipal uses, which were met exclusively at that time by local groundwater, were in the range of about 5,000 to 10,000 afy. By 1980, when supplemental surface water from the State Water Project (SWP) began to be imported to the basin, municipal water demands had increased to about 22,000 afy. Since then, municipal water demands have further increased, to their current level of about 61,000 afy, about 60 percent of which is supplied by SWP water, with the balance supplied by local groundwater. Current projections are for municipal water requirements to increase to about 106,000 afy over the next 20 years.

Historical and projected water requirements and supplies in the basin are discussed in more detail in Section IV of this Plan.

Water Code Section 10750 et. seq.

In 1992, the California State Legislature adopted Assembly Bill 3030 (AB 3030); that legislation was subsequently incorporated into the Water Code, Section 10750 et seq., to encourage local public agencies/water purveyors to adopt a formal plan to manage groundwater resources within



CAD FILE: G:/Projects/Castaic Lake Water/02-1-023/Figure 1-2.dwg CTB FILE: LSCE2500.PCP_MRG DATE: 04-03-03 10:40am

Figure 1-2
Santa Clara River Valley
East Groundwater Subbasin

their jurisdictions. Within the scope of Water Code Section 10753.8, a local groundwater management plan can potentially include up to twelve specific components. Although the plan need not be restricted to those specific components, the listed components are quite broad and cover essentially all of the groundwater management elements which are part of this plan or are likely to be considered for implementation into this plan in the foreseeable future. To a considerable extent, a number of the groundwater management activities listed in Water Code Section 10753.8 have been implemented in the Santa Clara River Valley East groundwater subbasin as part of an organized effort by the local municipal water purveyors, including CLWA, to manage the groundwater basin within its sustainable yield for the benefit of local water supply, and also to integrate management of the basin with the management of surface and groundwater immediately downstream on the Santa Clara River, in this case specifically with United Water Conservation District in Ventura County, as discussed in more detail herein.

The potential components of a groundwater management plan listed in Water Code Section 10753.8 include:

- the control of saline water intrusion.
- identification and management of wellhead protection areas and recharge areas.
- regulation of the migration of contaminated groundwater.
- the administration of a well abandonment and well destruction program.
- mitigation of conditions of overdraft.
- replacement of groundwater extracted by water producers.
- monitoring of groundwater levels and storage.
- facilitating conjunctive use operations.
- identification of well construction policies.
- the construction and operation by the local agency of groundwater contamination cleanup, recharge, storage, conservation, water recycling, and extraction projects.
- the development of relationships with state and federal regulatory agencies.
- the review of land use plans and coordination with land use planning agencies to assess activities which create a reasonable risk of groundwater contamination.

In 2002, the Legislature adopted Senate Bill 1938 (SB 1938) to amend and add to Water Code Section 10750 et seq. regarding the implementation of local groundwater management plans. While the provisions of SB 1938 did not alter the potential components of a local groundwater management plan, as listed above, it did add the following notable provisions:

- The local agency, in preparing a groundwater management plan, shall make available to the public a written statement describing how interested parties may participate in developing the plan; for purposes of carrying out the preceding requirement, the local agency may appoint, and consult with, a technical advisory committee consisting of interested parties. AB 134 actually anticipated this last item by requiring CLWA to form an Advisory Committee to review its Plan. The membership of the Advisory Committee was specified to consist of one representative from each retail water purveyor within CLWA and one representative from each groundwater producer within CLWA who pumped more than 100 acre-feet in the preceding water year (2000). In conformance with that requirement, CLWA formed an Advisory Committee consisting of representatives from the following organizations, who collectively fulfill the description of the membership specified in AB134:

    - CLWA Santa Clarita Water Division
    - Los Angeles County Sheriff's Department
    - Los Angeles County Waterworks District No. 36
    - Newhall County Water District
    - Newhall Land and Farming Company
    - Robinson Ranch
    - Valencia Water Company

- In order to qualify for funding assistance for groundwater projects or groundwater quality projects, for funds administered by DWR, a local agency must accomplish all the following relative to groundwater management:

    - prepare and implement, or participate in, or consent to be subject to, a groundwater management plan, a basin-wide management plan, or other integrated regional water management program or plan that meets the provisions listed below.

    - include groundwater management components that address monitoring and management of water levels, groundwater quality degradation, inelastic land subsidence, and changes in surface flows and quality that either affect groundwater or are affected by groundwater pumping.

- include provisions to cooperatively work with other public (and presumably private) entities whose service area or boundary overlies the groundwater basin.

- include mapping of the groundwater basin, as defined in DWR's Bulletin 118, and the boundaries of the local agency subject to the plan, plus the boundaries of other local agencies that overlie the basin.

- adopt monitoring protocols designed to detect changes in groundwater levels, groundwater quality, inelastic land subsidence (for basins where subsidence has been identified as a potential problem), and flow and quality of surface water that either directly affect groundwater, or are directly affected by groundwater pumping.

Of the potential groundwater management activities listed in Water Code Section 10753.8, those already being investigated and actively implemented as part of less formal groundwater management by the purveyors include avoidance of overdraft, implementation of conjunctive use, monitoring of groundwater levels and quality, initiation of groundwater contamination control, analysis of basin yield for ongoing avoidance of overdraft, and annual analysis and reporting on basin conditions. The historic focus of informal groundwater management in the Santa Clara River Valley East groundwater subbasin has been on water supply, quantity and quality, to avoid conditions of overdraft, primarily by augmenting local groundwater supplies with a supplemental, imported surface water supply from the State Water Project. More recently, efforts have been added to include ongoing monitoring and the compilation of data into a data management system that is integrated with a comparable database system for the downstream surface water resources and groundwater basins on the Santa Clara River. Recent efforts have also included initiation of a process to develop a numerical groundwater flow model of the basin for analysis of basin response to various water supply, recharge, and conjunctive use management alternatives that might be applicable for the basin. The potential groundwater management provisions not historically implemented have been those more focused on groundwater contamination; however, very recent activities have added this component to local groundwater management as a result of impacts on several municipal water supply wells from a former munitions manufacturing site in the basin, as discussed in more detail herein.

In summary, in many respects, the local municipal water purveyors, including CLWA, have already begun developing and implementing important parts of a formal local groundwater management program as part of developing reliable water supplies for in-basin needs. To ensure the reliability of the groundwater component of water supplies to meet existing and projected demands, those parts of local groundwater management planning already include monitoring, formulation of a data base, and integration with the database for adjoining downstream basins, analysis of groundwater conditions and annual reporting on water conditions in the basin, initiation of groundwater flow modeling, ongoing conjunctive use of local groundwater and imported SWP supplies, and initiation of investigation and control of localized groundwater contamination. The groundwater management plan described herein can be envisioned as a formalization, and some expansion, of those ongoing management efforts in the Santa Clara River Valley East groundwater subbasin.

The balance of this plan is organized to first establish a set of management objectives, or goals, for the basin; to then describe existing groundwater basin conditions, including areas of concern and identified problems; to present historical and projected water demands in the basin; and to finally present a set of groundwater management actions which, in aggregate, are the elements of this groundwater management plan.

II. Management Objectives (Goals) for the Basin

Prior to 1980, all water supplies in the Upper Santa Clara River Area were developed from local groundwater. Since 1980, the major water purveyors within the CLWA service area have developed their water supplies from a combination of local groundwater and imported supplemental surface water from the State Water Project (SWP). CLWA is the state SWP Contractor which holds the contract for SWP water. CLWA also operates the treatment and distribution system for delivery of SWP water to the local purveyors. Some imported SWP water has historically been delivered for non-municipal uses although, in aggregate, total non-municipal uses have been almost negligible (less than one percent).

A relatively small fraction of water supply in the area is still devoted to agricultural and other irrigation, and essentially all of that remains developed from groundwater. Over the last two decades, that use has been in a range between about 10,000 and 17,000 acre-feet per year.

The development and importation of a supplemental surface water supply from the State Water Project represents the first of a number of water resource and water supply management actions, all of which are formalized in this plan, aimed at what can be considered to be the overall goals or objectives for the basin. In no priority, those management objectives for the basin can be expressed as follows:

1. Development of an integrated surface water, groundwater, and recycled water supply to meet existing and projected demands for municipal, agricultural, and other water supply; since pumpage for other uses is from the same aquifer system, this objective includes agricultural, small community, non-agricultural irrigation, and individual domestic uses.

2. Assessment of groundwater basin conditions to determine a range of operational yield values that will make use of local groundwater conjunctively with SWP and recycled water to avoid groundwater overdraft and the undesirable effects associated with it. In effect, this objective equates to more detailed quantification of the yield of the basin in order to continue to avoid overdraft, consistent with what has historically been the case in the basin. In addition to avoiding the traditional overdraft symptoms

and effects, e.g. chronic water level decline, loss of groundwater storage, onset of land subsidence, groundwater quality degradation, a corresponding basin objective is to manage groundwater levels and associated groundwater discharge to the Santa Clara River at the west end of the basin, and thus not adversely impact surface and groundwater discharges to the downstream basin(s).

3. Preservation of groundwater quality for beneficial use in the basin, and for beneficial use of surface water and groundwater discharges from the basin. Included in this management goal will be the active characterization and solution of any groundwater contamination problems, through cooperation with responsible parties or through independent action if timely action by responsible parties is not forthcoming and the preceding management objectives are thereby impacted or constrained.

4. Preservation of interrelated surface water resources. Included in this management goal will be the maintenance of appropriate surface water flows and non-degradation of surface water quality as a result of managing groundwater conditions to meet the other management goals for the basin.

Quantitatively, the preceding goals translate into general preservation of groundwater levels and quality in the Alluvial aquifer system consistent with the last 30 years, including fluctuations through seasonal demands and local hydrologic variations (wet and dry periods). As discussed in more detail in the next chapter, the hydrogeologic setting in the area has resulted in smaller Alluvial groundwater level fluctuations toward the western half of the basin (generally west of Bouquet Canyon), and larger fluctuations to the east. However, largely due in part to the importation of supplemental surface water over the last 20 years, and the integrated or conjunctive use of that supplemental water with local groundwater, there has been no chronic decline in groundwater levels or storage. A continuation of such basin conditions, possibly complemented by management actions to decrease the historical water level fluctuations in the eastern part of the basin, will accomplish the second basin objective (continued avoidance of overdraft as has been the ongoing historical condition in the basin) while continuing to utilize local groundwater to meet part of projected water requirements. Corresponding management actions to sustain recharge and not overdraft groundwater storage will accomplish the third basin objective by replenishing the aquifer system with sufficient water to sustain what has been generally consistent quality of groundwater on a long-term basis.

In general, the same goals of preservation of groundwater levels and quality pertain to the Saugus Formation as well as to the Alluvium. However, while those goals are generally expected to equate to Alluvial pumping rates comparable to recent historical pumping, the Saugus Formation may be intermittently utilized at higher than historical pumping rates for dry-period and/or emergency water supply. Interpretation of historical pumping fluctuations and corresponding aquifer response suggests that such intermittent utilization of a small fraction of the Saugus' large storage capacity can successfully contribute to a firming of local water supplies while still accomplishing all the management objectives listed above, primarily via reduction in Saugus pumping during wet-normal conditions, possibly complemented by management actions to accelerate recharge of the Saugus.

III. Groundwater Basin Conditions

Occurrence of Groundwater

Groundwater in the Santa Clara River Valley East groundwater subbasin occurs in two aquifer systems, the Alluvium associated with the Santa Clara River and its tributaries, and the Saugus Formation. There are also some scattered outcrops of Terrace deposits in the basin that likely have the capacity to contain limited amounts of groundwater; however, since these deposits are located in limited areas that are situated at elevations above the regional water table and are also of limited thickness, they are of no practical significance as aquifers and have consequently not been developed for water supply.

The Alluvial aquifer system, of Quaternary to Holocene (Recent) geologic age, consists primarily of stream channel and flood plain deposits of the Santa Clara River and its tributaries. The Alluvium is deepest along the center of the present river channel, with a maximum thickness of about 200 feet near the area known as Saugus. It thins toward the flanks of the adjoining hills and toward the eastern and western boundaries of the basin and, in the tributaries, becomes a mere veneer in their upper reaches. The spatial extent of the Alluvium throughout the basin is illustrated in Figure 3-1.

The Alluvium is the most permeable of the local aquifer units. Based on well yields and aquifer testing, transmissivity values in the range of 50,000 to 500,000 gallons per day per foot (gpd/ft) have been reported for the Alluvium, with the higher values where the Alluvium is thickest in the center of the valley and generally west of Bouquet Canyon (Slade 1986 and 2002). The amount of groundwater in storage can vary considerably because of the effects of recharge, discharge and pumping from the aquifer. The maximum storage capacity of the Alluvium has been estimated to be about 240,000 acre-feet (af) (Slade, 1986 and 2002).

The Saugus Formation, of Pliocene to Pleistocene geologic age, has traditionally been divided into two stratigraphic units: the lowermost, geologically older Sunshine Ranch member, which is of mixed marine to terrestrial (non-marine) origin; and the overlying, or upper, portion of the Formation which is entirely terrestrial in origin. The Sunshine Ranch Member of the Saugus Formation has a maximum thickness of about 3,000 to 3,500 feet in the central part of the valley;

however, due to its marine origin and fine-grained nature, it is not considered to be a viable source of groundwater for municipal or other comparable supply. Above the Sunshine Ranch Member, the Saugus Formation is coarser grained, consisting mainly of lenticular beds of sandstone and conglomerate that are interbedded with lesser amounts of sandy mudstone, which were deposited in stream channels, flood plains, and alluvial fans by one or more ancestral drainage systems in the valley. The sand and gravel units that represent aquifer materials in the upper part of the Saugus Formation are generally located between depths of about 300 and 2,500 feet. The spatial extent of the Saugus Formation throughout the basin is illustrated in Figure 3-1.

While much thicker and more spatially extensive throughout the basin when compared to the Alluvium, and while significant in terms of groundwater storage and individual well capacity, the Saugus Formation has typically lower values of transmissivity, in the range of 80,000 to 160,000 gpd/ft, with the higher values in the upper portions of the Formation (Slade, 1988 and 2002). The storage capacity of the Saugus has most recently been estimated to be 1.65 million acre-feet between depths of 300 feet and 2,500 feet (or the base of the Saugus or the base of fresh water if shallower than 2,500 ft.) (Slade, 2002).

Historical Groundwater Development

Of the two aquifer systems in the basin, the predominant development of groundwater for agricultural and municipal water supply has historically been from the Alluvium, a condition that remains the case at present. Prior to 1980, all water supply in the valley was developed from local groundwater; since 1980, local groundwater has been supplemented by imported surface water from the State Water Project. Details of historical water requirements, and water supplies to meet those requirements, are discussed and illustrated in Chapter IV of this Plan.

In general, over the last two decades, since the inception of SWP deliveries in 1980, total pumpage from the Alluvium has ranged from a low of about 20,000 afy (in 1983) to slightly more than 43,000 afy (in 1999). For comparison, agricultural pumpage from the Alluvium throughout the 1950's was consistently in the range of about 33,000 to 41,000 afy. During that same time, municipal pumpage was quite small, less than 4,000 afy. Overall, over the last two decades, there has been a change in municipal/agricultural pumping distribution, toward a slightly higher fraction for municipal water supply (from about 50% to nearly 60% of alluvial pumpage) which is indicative of the general land use changes in the area.

LUHDORFF & SCALMANINI CONSULTING ENGINEERS

Figure 3-1
Alluvial and Saugus Formations
Santa Clara River Valley East Groundwater Subbasin

Since 1980, total pumpage from the Saugus Formation has ranged between about 3,850 afy and nearly 15,000 afy; average pumpage over that period has been about 6,900 afy. The great majority of pumpage from the Saugus is for municipal supply (nearly 6,300 afy, or 92 percent, on average). For comparison, although historical Saugus pumping records prior to 1980 are limited, there appears to have been essentially no pumping from the Saugus prior to 1960 (on the order of about 100 af in most years, beginning in 1948), and some increased pumping for agricultural water supply beginning in about 1962 (about 900 af). The largest amount of agricultural pumping from the Saugus was during the mid-1960's, when annual Saugus pumpage was about 3,000 af. Agricultural pumping from the Saugus declined to near zero by the late 1970's, but has been generally in the 500 to 1,000 afy range since 1982. There was no Saugus pumpage for municipal supply in the early 1960's; limited data suggests that municipal pumping from the Saugus began in the 1970's, and reached nearly 5,000 afy by 1980-81. The most significant period of Saugus pumpage was 1991 through 1994, when pumpage ranged from 10,600 afy to nearly 15,000 afy and averaged over 12,000 afy, during which time SWP water deliveries were reduced at the end of extended drought conditions.

Groundwater Monitoring Network and Program

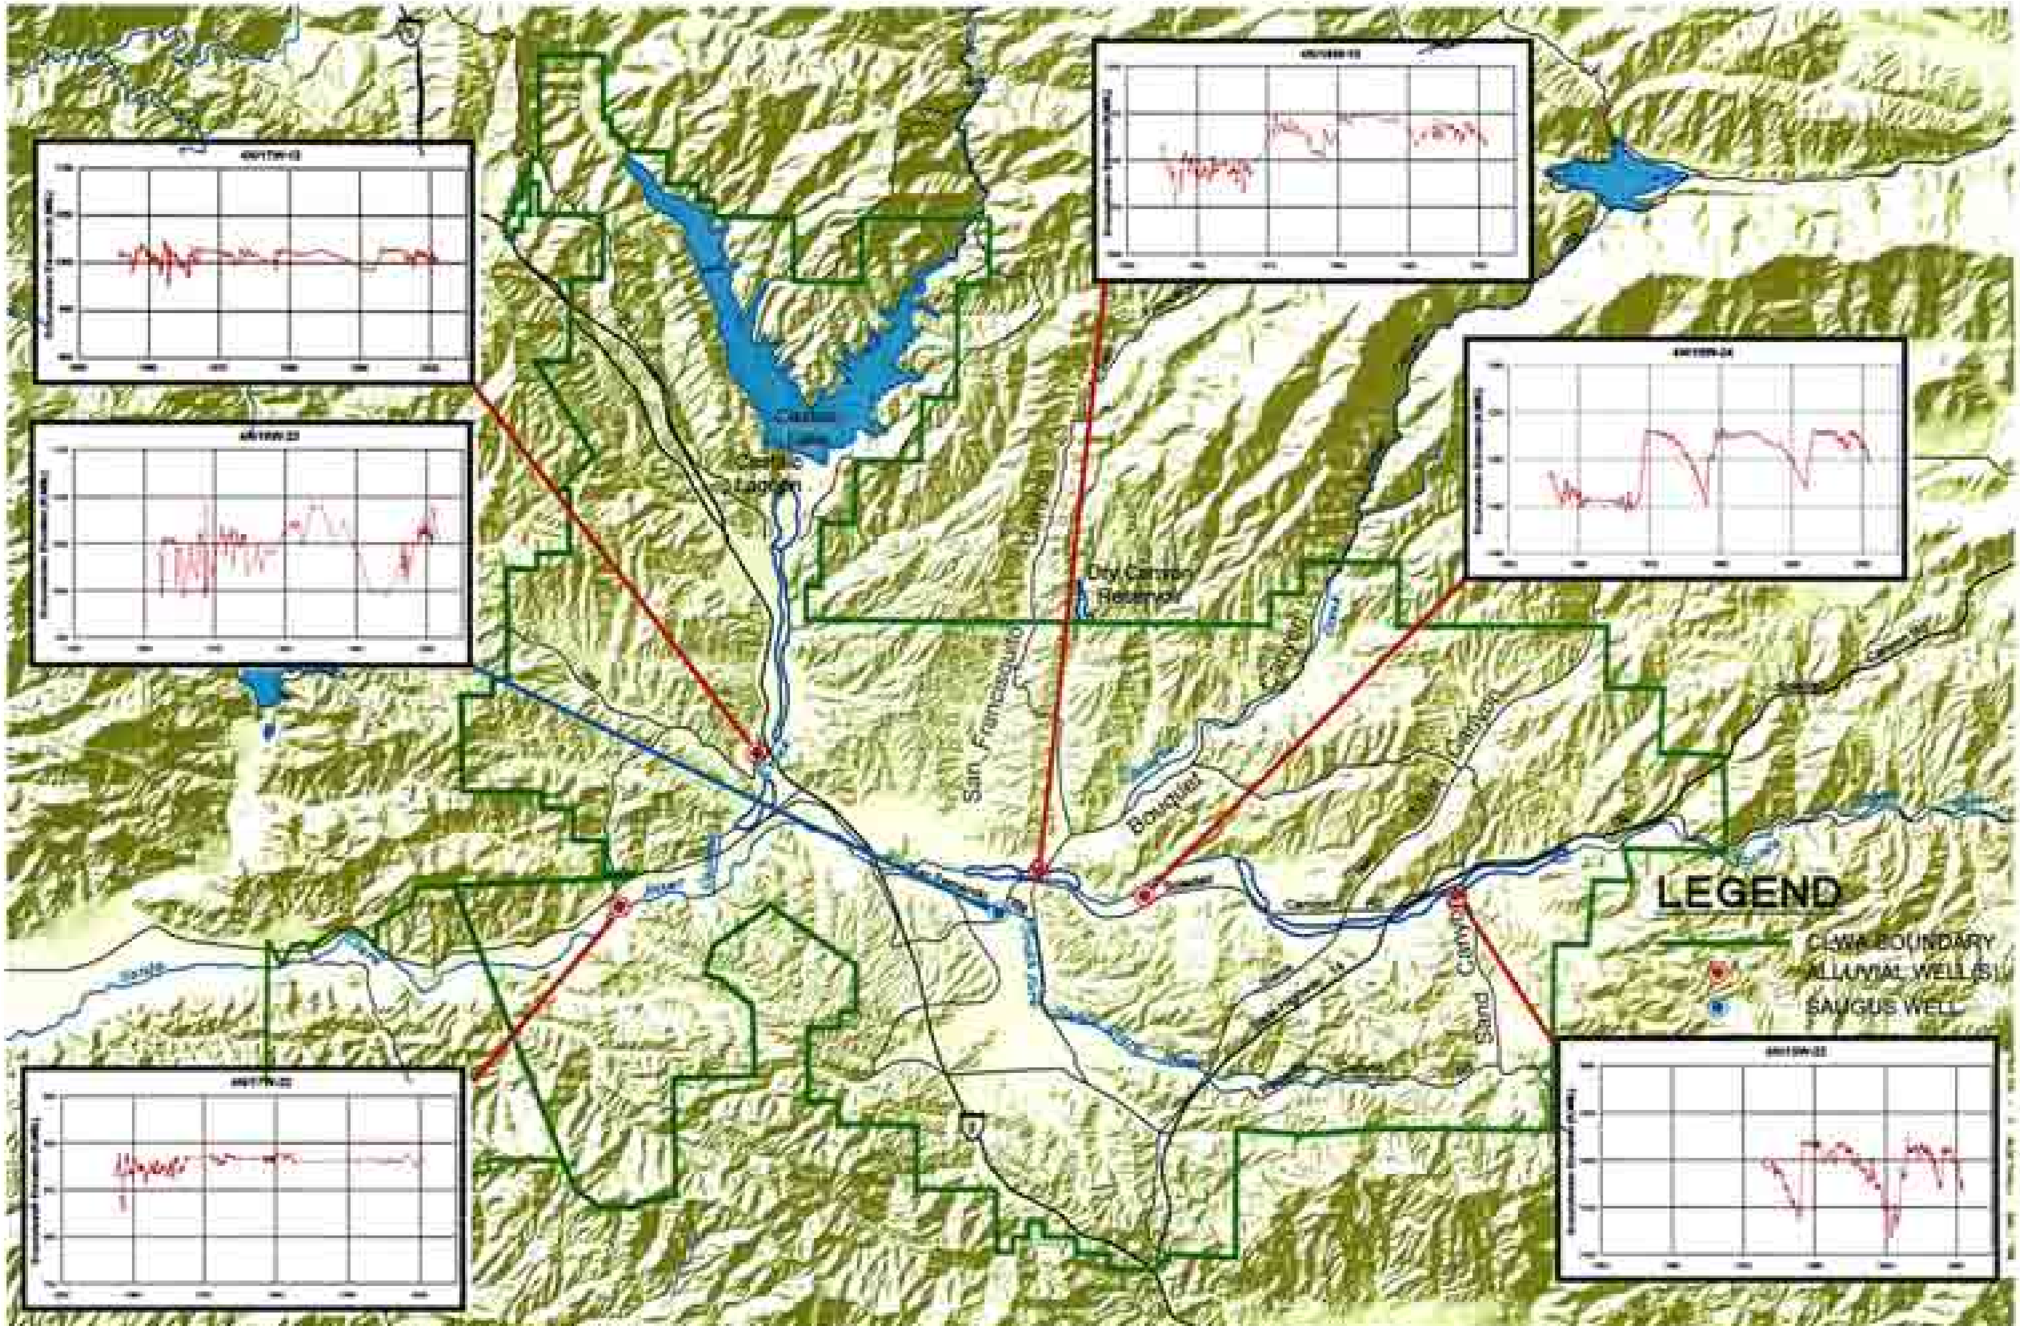
There is no formal groundwater monitoring network of wells for groundwater level measurements and/or groundwater quality sampling in the basin. Consequently, one component of this Plan is to formalize both a network of wells for groundwater monitoring and a program for water level measurements, water quality sampling, and other pertinent groundwater data collection (Primary Plan Element 1). Despite the lack of an existing formal groundwater monitoring network and program, however, there is a significant amount of historical groundwater data, some of which dates back into the 1940's, on which to base reasonable assessments of groundwater conditions in the basin. For example, groundwater level measurements have been made over varying periods of record in a total of 154 wells, mostly alluvial wells, throughout the basin. Similarly, groundwater quality data, consisting of varying numbers of constituents analyzed, are available from some wells, but a much smaller number than is the case for groundwater level data. These data, along with direct measurements or indirect estimates of pumpage, primarily from high capacity municipal and agricultural wells, allow for analysis of groundwater basin conditions, as discussed in this Plan, and also provide the bases on which a groundwater model can be developed (Primary Plan Element 3) and on which various management criteria such as operational yield, baseline groundwater quality, etc. can be determined (Primary Plan Elements 3, 6, etc.).

Groundwater Levels and Storage

Groundwater level data in various parts of the basin illustrate basin response to the historical pumpage from the Alluvium. Organized into hydrograph form (depth to groundwater or groundwater elevation vs. time), historical groundwater levels were lower in the 1950's and 60's than current levels in the middle to western part of the basin, logically in response to the higher pumpage of the 1950's before the importation of SWP water and the associated increase in return flows to the river that have augmented groundwater recharge in that part of the basin. Groundwater levels in those areas notably recovered as pumpage declined through the 1960's and 1970's. They have subsequently sustained generally high levels for much of the last 30 years, with two dry-period exceptions: mid-1970's and late 1980's - early 1990's; recoveries to previous high groundwater levels have followed both of those dry-period declines. Based on this data, there is no evidence of any historic or recent trend toward permanent water level or storage decline. In general, throughout the Alluvium, groundwater levels have been generally higher over the last 30 years than was consistently the case for the preceding 20 years (1950's - 60's).

During the last 20 to 30 years, in essentially all the alluvial portions of the basin, groundwater levels have fluctuated from near the ground surface when the basin is full, to as much as 100 feet lower during intermittent dry periods of reduced recharge. Selected hydrographs of groundwater elevations illustrate the above described conditions throughout the basin. Figure 3-2 illustrates groundwater level conditions and trends at multiple locations in the Alluvium along the main channel of the Santa Clara River, from east near the mouth of Sand Canyon, to the area between Mint Canyon and Bouquet Canyon, to farther west immediately below the mouth of Bouquet Canyon. Similar long-term conditions are evident in the tributary canyons.

A comment about some of the groundwater fluctuations illustrated in Figure 3-2 is appropriate since they are illustrative of the most substantial intermittent changes in the basin. As noted above, the Alluvium has historically experienced a number of alternating wet and dry hydrologic conditions as illustrated in Figure 3-2. Since the Alluvium is thinner to the east, the fluctuations in water levels of 75 to 100 feet impact well yields and pumping capacities when water levels are occasionally lower. When that occurs, as is currently the case due to locally dry hydrologic conditions, the affected purveyors shift a portion of their water demands to imported SWP water, thus reducing pumpage and reducing drawdown of water levels. Recovery of groundwater levels



CAD FILE: C:/Projects/Castaic Lake Water/02-1-023/Figure 3-2.dwg CFG FILE: LSCE2500.PCP_MRG DATE: 04-03-03 4:37pm

Figure 3-2
Historical Groundwater Elevations
Santa Clara River Valley East Groundwater Subbasin

and storage occurs upon a return of stream flow to contribute to natural recharge.

Depending on the period of available data, all the hydrographs of alluvial groundwater levels show the same general picture: recent (last 30 years) groundwater levels are generally higher than over the preceding 20 years. In some locations, there are intermittent dry-period declines (and an associated use of some groundwater from storage) followed by wet-period recoveries (and associated refilling of storage space). On a long-term basis, whether over the last 20 years since the inception of conjunctive use via importation of SWP water, or over the last 40 to 50 years, the Alluvium shows no signs of water level-related overdraft, i.e., no trend toward decreasing groundwater levels and storage, a condition that is intended to be maintained via implementation of this Plan, e.g. via Primary Plan Elements 3 and 5.

Unlike the Alluvium, there are limited Saugus water level data; however, the limited data indicate that, although there have been seasonal water level changes in response to pumpage, the long-term trend in the Saugus (over the last 35 to 40 years) has been one of relative groundwater level stability (see, for example, Figure 3-2). There is no trend toward a sustained decline in Saugus water levels or storage that would be indicative of overdraft.

Land subsidence as a result of groundwater extractions is a concern in a number of groundwater basins in California. The potential for land subsidence caused by groundwater extractions derives from a combination of the geologic makeup of the aquifer materials and the history of groundwater level fluctuations. In the Santa Clara Valley East Subbasin, the most notable groundwater level fluctuations have occurred in the Alluvium to the east of Bouquet Canyon, with the greatest fluctuations (up to nearly 100 feet) recorded in the vicinity of Sand Canyon. Fortunately, those fluctuations have been intermittent, and have varied directly with local wet and dry conditions. From a subsidence perspective, they have also fluctuated in an unconfined aquifer that is comprised of essentially all coarse-grained material. The lack of any significant fine-grained material in the aquifer where groundwater levels have fluctuated results in two notable local conditions in regards to subsidence: there is no recorded historical subsidence or indirect evidence of its occurrence, i.e. subsidence-related impacts on surface structures, drainage facilities, etc.; and there is minimal potential for inelastic subsidence to occur in response to ongoing groundwater level fluctuations in the Alluvium.

The Saugus Formation contains a greater fraction of fine-grained material interbedded with the coarser aquifer materials that yield water to wells. Consequently, the Saugus has a greater potential to undergo consolidation, with attenuant subsidence impacts at the ground surface, if groundwater levels are substantially lowered for long time periods. Historical Saugus pumping has not caused such conditions to occur. Current water supply planning, as described in this Plan, is to rely on the Saugus Formation for a relatively small component of water supply on an ongoing basis, with intermittent increased pumping during dry periods.

The long-term objective for groundwater management, as described in this Plan, is to not overdraft either the Alluvium or the Saugus, i.e. to not chronically lower groundwater levels. Satisfaction of the latter objective will have the correlative impact of minimizing the potential for inelastic land subsidence attributable to pumping from the Saugus Formation; combined with the lack of fine-grained material in the Alluvium, satisfaction of that objective will also have the correlative impact of ensuring the improbability of any subsidence attributable to pumping from that aquifer.

Groundwater Quality

Groundwater quality is, or course, a key factor in assessing both the Alluvial aquifer and the Saugus Formation as municipal and agricultural water supplies. At present, however, there is no convenient long-term record of water quality, i.e. water quality data in one or more wells that span several decades and continue to the present. Thus, in order to examine a long-term record of water quality in the Alluvium, an integration of individual records from several wells, completed in the same aquifer materials and in close proximity to each other, can be used to generally show long-term trends in groundwater quality. Figure 3-3 illustrates groundwater quality conditions and trends at multiple locations in the Alluvium along the main channel of the Santa Clara River from the area near the mouth of Mint Canyon, to areas immediately above and near the mouth of Bouquet Canyon, to the area below San Francisquito Canyon. Based on these records of groundwater quality, there have been historical fluctuations in concentrations of total dissolved solids (TDS), as well as corresponding fluctuations of individual constituents of TDS. In general, however, and similar to groundwater levels, there has been no long-term trend toward groundwater quality degradation.

Groundwater quality variations are common throughout the Alluvium and generally correlate inversely with precipitation and stream flow: wet periods have produced substantial recharge of higher quality (low TDS) water and dry periods have resulted in the notable declines in water levels described above, with a corresponding increase in TDS (and individual component

CONSULTING ENGINEERS

Figure 3-3
Historical Groundwater Quality by Section
Santa Clara River Valley East Groundwater Subbasin

constituents) in the deeper parts of the Alluvium.

Due to a much more limited number of wells and the limited spatial extent of groundwater development in the Saugus Formation, long-term Saugus groundwater quality data are not sufficiently extensive to permit any sort of basin-wide analysis or assessment of pumping-related impacts on quality. Based on the most complete historical record, over the last 35 years, however, groundwater quality in the Saugus has remained generally constant. The Saugus Formation is, on a groundwater quality basis, a viable agricultural and municipal water supply.

The most notable groundwater quality issue in the basin centers around the detection and impact of perchlorate on several Saugus wells and one Alluvial well in the central part of the basin near the location of the former Whittaker Bermite facility, which is immediately southeast of the confluence of the main Santa Clara River and its South Fork tributary. In 1997, routine water quality sampling detected the presence of perchlorate in four municipal wells completed in the Saugus Formation (CLWA Santa Clarita Water Division Saugus Wells 1 and 2, Newhall County Water District Well 11, and Valencia Water Company Well 157). While there remains no primary or secondary drinking water standard for perchlorate, and although only some of the detected concentrations of perchlorate in the Saugus wells exceeded the Action Level established by the State Department of Health Services at that time (18 ug/l), all those wells were inactivated by their respective owners after detection of perchlorate; those wells remain out of municipal water supply service since then.

More recently, in late 2002, routine water quality sampling of Alluvial wells detected perchlorate in one of them (CLWA Santa Clarita Water Division Stadium Well) at a concentration which slightly exceeds the current Action Level (4 ug/l). This well has also been voluntarily inactivated, and remains removed from municipal water supply service.

This Plan, notably through Primary Plan Elements 1, 6 and 8, is intended to incorporate both short-term and long-term groundwater quality considerations in the management of the groundwater basin in order to formalize groundwater quality monitoring and assessment, to investigate and correct groundwater contamination problems, and to preserve or improve groundwater quality for ongoing water supply as well as for avoiding adverse water quality impacts on interconnected surface waters.

Areas of Concern and Identified Problems

A number of concerns have been expressed about groundwater conditions in the basin. While not all of the expressed concerns have been substantiated, they are listed and briefly discussed here, and they are addressed in the management objectives for the basin, intended to be achieved via implementation of the various primary and secondary elements in this Plan.

At present, the most notable concern in the basin is the impact of perchlorate contamination on a number of municipal water supply wells, thus affecting the available pumping capacity from some municipal wells. While perchlorate impacts on a few wells do not preclude the ability to pump groundwater in accordance with existing water supply plans, activities to characterize the contamination, and ultimately to control it and treat it, have been initiated in order to return the impacted wells' pumping capacity to water supply service. Primary Element 8 is included in this Plan to formalize the addressing of groundwater contamination issues in the basin.

Concern has also been expressed that groundwater development in the basin will adversely impact the quantity and/or quality of surface flows leaving the basin via the Santa Clara River. Such concern extends to the potential impact on groundwater in the next downstream basin, the Piru Basin in Ventura County. While there are no established provisions regarding surface flows out of the Santa Clara River Valley East subbasin, Primary Element 2 is included in this Plan to formally address the monitoring and management of surface water flows and quality within, and flowing out of, the basin. Some work is already ongoing related to this area of concern via a Memorandum of Understanding (MOU) among CLWA, other retail water purveyors within CLWA's service area, and United Water Conservation District, which manages surface water and groundwater in the downstream basins on the Santa Clara River in Ventura County. That cooperative effort, which is incorporated into this Plan via Primary Element 9, includes integration of databases, development of a numerical groundwater flow model, and interpretation and reporting on surface water and groundwater conditions.

A third expressed concern in the basin, is that groundwater is already overdrafted. Associated with that expressed concern is a related issue that reliance on overdrafted groundwater results in an overstated water supply in the basin. As discussed earlier in this section, long-term groundwater levels, storage, and quality all indicate the basin is in balance (i.e., no overdraft exists). As also discussed above, the importation of supplemental surface water over the last 23 years, and the associated initiation of conjunctive use operations have directly resulted in an overall adequacy of water supplies while sustaining an undepleted groundwater supply. Primary Elements 3, 4 and 5 are key parts of this Plan to more formally quantify the yield of the groundwater basin, and to continue to meet overall water requirements via continuation of conjunctive use of local groundwater with imported supplemental surface water, ultimately complemented by integration of recycled water for non-potable water supply (Primary Element 7).

Finally with regard to areas of concern in the basin, the historically larger fluctuations in the eastern part of the basin have been highlighted for their impacts on private wells in that area. Some focused study has been done to address whether certain pumping directly affects private wells in Sand Canyon; its conclusions were that such direct effects were not occurring. Subsequently, a nearby development contracted for delivery of up to 120 acre-feet of imported SWP water from CLWA in order to reduce its use of groundwater for domestic and irrigation water supply. Primary Element 1 is partly intended to acquire site-specific data regarding private wells, their locations, the aquifers in which they are completed, their yields and pumping capacities as well as their quality, and their water level records. Primary Element 3 is partly intended to analyze such data in order to assess whether local aquifer depletion is occurring and, if so, what remedy is appropriate.

IV. Historical and Projected Water Requirements and Supplies

Historical Water Requirements

The initial development of water supplies in the Santa Clarita area began in the 1800's for irrigation on the San Francisquito Ranch after its purchase by Henry Mayo Newhall. While there are some records in the form of waterworks drawings that show early diversion and distribution facilities on the ranch in 1911 and some mapping of well locations in the 1930's, the earliest complete records of water use date from shortly after the end of World War II. From 1947 through the mid 1960's, groundwater pumping for agriculture ranged from about 27,000 to about 42,000 acre-feet per year (afy). For most of the same period, until 1960, there are no detailed records of water use for municipal supply. The first records of municipal water use begin in 1960, when municipal water requirements were about 5,000 afy; by the mid-1960's, municipal water requirements had increased to about 10,000 afy. Throughout that time, all municipal water supply was from local groundwater.

From the mid-1960's through about 1980, groundwater pumping for agricultural water supply declined into the range of about 10,000 to 15,000 afy. In the late 1980's through the early 1990's, agricultural groundwater pumping further declined into the range of about 8,000 to 10,000 afy; over about the last ten years, agricultural water requirements, which continue to be fully met by local groundwater pumping, have been in the range of about 12,000 to 15,000 afy. The history and trends of agricultural water use in the basin are illustrated in Figure 4-1.

Detailed records of municipal water use are not available from the mid-1960's through 1980, when imported surface water was first used in the basin for municipal water supply. However, the available municipal water use data at the beginning and at the end of that period, combined with estimated declining agricultural water use for the same period, suggest there was a generally steady increase in municipal water use from about 11,000 af in 1966 to about 22,000 af in 1980. Since then, municipal water use has increased to about 68,000 afy. With the addition of imported surface water from the State Water Project beginning in 1980, however, groundwater pumping for municipal supply declined in the early 1980's. Throughout the 1990's, municipal pumping fluctuated between about 27,000 and 32,000 afy. The history and trend of municipal groundwater use in the basin are illustrated in Figure 4-1.

As noted above, until 1980, all water supply in the basin was from local groundwater. Imported surface water was first available from the State Water Project (SWP) in 1980, when a total of 1,125 af were imported into the basin. Since then, importations of SWP water have increased in two separate steady trends, interrupted by a notable decrease at the end of, and following, the 1987-1992 drought period: a steady increase beginning in 1980, to about 21,600 afy in each of 1989 and 1990, followed by a substantial decrease, to less than 8,000 af in 1991, and then a steady increase back to about 21,000 afy in 1997 and 1998, followed by further increases to nearly 42,000 af in 2002. The history and trends in importation of SWP water to the basin are illustrated in Figure 4-2, which also illustrates the historical trends in groundwater pumping and total water use in the basin since the importation of SWP water.

In the context of this groundwater management plan, the historical utilization of imported SWP water to augment local groundwater represents the initiation of conjunctive use of surface water and groundwater supplies, a groundwater management principle which is intended to be continued via adoption of Primary Element 5 of this plan.

Projected Water Requirements

Detailed projections of municipal water requirements were most recently completed as part of the Urban Water Management Plan prepared by CLWA and the municipal water purveyors (Newhall County Water District, Santa Clarita Water Company, and Valencia Water Company) in 2000. Those projections, which are forecast for a 20-year period, also recognize an ongoing but decreasing agricultural water demand over the same period, from about 15,000 afy in 2005 to about 7,000 afy by 2020. The municipal water demand projections in the Urban Water Management Plan are derived from utilization and interpretation of multiple projection methods, including per-capita water-use applied to population projections; extrapolation of number of service connections (using two different projection techniques, an average rate and an accelerated rate projection) applied to the rate of service connection additions since 1990; and land use projections combined with unit water use factors on multiple land use categories (urban, including residential, commercial, industrial and recreational; irrigated agricultural; and vacant and open space). The water demand projections in the Urban Water Management Plan also consider weather effects (variations due to hot-dry years vs. cool-wet years) and conservation

effects on water usage.

The net result of application and interpretation of the various water demand projection methods in the 2000 Urban Water Management Plan is summarized in Figure 4-2, which reflects projected urban and agricultural water demand through 2020, absent potential increased conservation savings, which are estimated to be ten percent of urban water demand. Numerically, urban water use without increased conservation savings is projected to increase to nearly 67,000 afy by 2005, and then continue to increase to 106,000 afy by 2020. As noted above, agricultural water use over the same period is projected to decrease to 15,000 afy by 2005, followed by an ongoing decrease to 7,100 afy by 2020. In addition to the graphical presentation of projected water demands in the basin through 2020 in Figure 4-2, projected water demands are tabulated, both with and without potential increased conservation savings, in Table 4-1.

Total Projected Demand	**81,700**	**90,100**	**100,700**	**113,100**
Increased Conservation Savings	6,600	7,700	9,100	10,600
Total Projected Demand *(with increased conservation)*	**75,100**	**82,400**	**91,600**	**102,500**

Existing and Projected Water Supplies

As noted above, existing water supplies to meet current water demands are comprised of local groundwater and imported SWP surface water. In 2001, for example, to meet a total water demand of nearly 76,800 af, local groundwater pumping amounted to 41,400 af, (about 54% of total demand) and imported SWP water amounted to 35,400 af (about 46% of total demand).

Water supplies to meet projected water demands are expected to continue to be primarily a combination of local groundwater and imported SWP surface water, augmented by local recycled

water and possibly some water supply derived from water transfers and desalination outside the basin.

Local Groundwater - Local groundwater has historically been developed from the two aquifers that comprise the groundwater basin, the Alluvium that underlies the Santa Clara River and its tributaries, and the Saugus Formation that underlies much of the CLWA service area. Those two aquifers, and the groundwater basin they comprise, are the focus of this groundwater management plan. Based on historical experience and observation of groundwater conditions, it is currently expected that ongoing utilization of local groundwater will continue to be in amounts that are generally comparable to what has historically been pumped, 30,000 to 40,000 afy from the Alluvium and 7,500 to 15,000 afy from the Saugus Formation. It is also expected that there is some additional development potential in the Saugus Formation, in the range of 10,000 to 20,000 af which might be intermittently extracted during one or more dry years when supplemental imported water supplies might be reduced. Ultimately, it is expected that local groundwater will continue to be a component of water supply in the basin at appropriate production levels from both aquifers. The intent of this groundwater management plan is to ensure that ongoing utilization of local groundwater continues to result in acceptable aquifer conditions, i.e. avoidance of overdraft (Primary Plan Element 3), no degradation of quality (Primary Plan Element 6), no adverse impacts to surface waters (Primary Plan Element 2), all via continuation of conjunctive use operations that have been ongoing since the initial importation of supplemental surface water in 1980 (Primary Plan Element 5) and via monitoring and interpretation of surface water and groundwater conditions on an ongoing basis (Primary Plan Elements 1 and 2).

Supplemental (SWP) Surface Water - CLWA has a Table A contract amount of 95,200 af of water from the SWP. CLWA's original contract, signed in 1963, was for 23,000 af; that Table A amount was later increased to 41,500 af. In 1988, CLWA purchased a Table A amount of 12,700 af from Devil's Den Water District, and it acquired another 41,000 af of Table A amount in 1999 from Kern County Water Agency and its member district, the Wheeler Ridge-Maricopa Water Storage District. There is ongoing CEQA-related litigation over the most recent acquisition of the 41,000 af Table A amount. However, there has been no invalidation of the completed agreement to transfer the 41,000 af Table A amount to CLWA and current water supply planning includes that Table A amount as CLWA corrects the CEQA technicality by preparing a new EIR to address the environmental consequences of the transfer.

Recycled Water - In 1993, CLWA prepared a draft Recycled Water System Master Plan that outlined a multi-phase program to integrate recycled water into the overall water supply system in the basin. Phase I of that project, which will deliver approximately 1,700 afy, began deliveries of recycled water for golf course irrigation in mid-2003. Overall, by 2020, recycled water is expected to ultimately reclaim up to 17,000 afy of treated waste water suitable for irrigation of golf courses, landscaping, and other non-potable uses.

V. Elements of the Groundwater Management Plan

As part of long-term water supply planning in the Santa Clara River Valley East groundwater subbasin, Castaic Lake Water Agency (CLWA) and the municipal water purveyors in the basin, in concert with other groundwater pumpers in the basin, began conjunctive use operations in 1980 by importing supplemental surface water from the State Water Project and integrating it with local groundwater to meet all the water requirements in the basin. Prior to that time, and continuing to the present, various groundwater pumpers and other entities in the basin, including CLWA, have collected groundwater and related data on which historical and ongoing analyses of groundwater basin conditions have been made. Those monitoring efforts and basin analyses have allowed CLWA and other entities in the basin to progressively define and understand basin conditions, and to continue to meet increasing water demands over the last 23 years. Information derived from the monitoring and management efforts to date has allowed the various public and private pumpers in the basin to continue to rely on the groundwater basin for some or all of their water supply without significant concern that the resource was either overdrafted or otherwise negatively impacted.

In light of the preceding, complemented most recently by the Memorandum of Understanding process that has initiated integrated management with United Water Conservation District, which serves as the manager of adjacent downstream basins on the Santa Clara River (as described in Primary Element 9), local groundwater management has already been initiated consistent with the opportunity provided by Water Code Section 10753. However, despite those ongoing accomplishments, CLWA recognizes the concerns and issues that are discussed herein relative to groundwater and the adequacy of water supplies in the basin. With that recognition, and in part prompted by the requirements of AB 134, CLWA has prepared this broader-based groundwater management plan.

To continue historical groundwater management activities and to address identified concerns and issues related to groundwater and water supply in the area, this Groundwater Management Plan has been developed to provide a framework for present and future actions. As has been the case for the groundwater management activities by CLWA and other local entities over the past 23 years, it is expected that this plan will be updated as new data are developed, particularly in light of the key role that groundwater monitoring (water levels and quality) has played, and will continue to play, in defining groundwater conditions and aquifer response to management actions.

The management objectives, or goals, for the Santa Clara River East groundwater basin include the following:

Goal 1: Development of Local Groundwater for Water Supply
Goal 2: Avoidance of Overdraft and Associated Undesirable Effects
Goal 3: Preservation of Groundwater Quality
Goal 4: Preservation of Interrelated Surface Water Resources

To accomplish those goals, with recognition of the opportunities encouraged by Water Code Section 10750 et seq. for local agency management of groundwater resources, this plan incorporates a number of components which are divided into primary, or essential, elements and secondary, or potential, elements. In both categories, the elements formally recognize the effectiveness of a number of ongoing water resource management activities. They recognize the need for additional activity, such as expanded conjunctive use of supplemental surface water, and recycled water, with local groundwater. They also reflect the wider focus on local groundwater management, such as continuing cooperation with the municipal water purveyors and other pumpers in the basin, and with other water resource management entities on the Santa Clara River, most notably United Water Conservation District, to address the impacts of regional resource opportunities and/or challenges. In summary, this Groundwater Management Plan will enable CLWA, the retail water purveyors, and their neighbors to continue use of local groundwater for regular water supply, to expand their use of local groundwater during dry periods or emergencies, and to work with other agencies via implementation of the following management plan elements.

Primary (Essential) Plan Elements

1. Monitoring of Groundwater Levels, Quality, Production and Subsidence
2. Monitoring and Management of Surface Water Flows and Quality
3. Determination of Basin Yield and Avoidance of Overdraft
    - wet and dry period pumping
    - control of well field drawdown

4. Development of Regular and Dry Year/Emergency Water Supply
5. Continuation of Conjunctive Use Operations
6. Long Term Salinity Management
7. Integration of Recycled Water
8. Identification and Mitigation of Soil and Groundwater Contamination
    - involvement with other local agencies in investigation, cleanup, and closure
9. Development and Continuation of Local, State and Federal Agency Relationships
10. Groundwater Management Reports

Secondary (Potential) Elements

1. Continuation of Public Education and Water Conservation Programs
2. Identification and Management of Recharge Areas and Wellhead Protection Areas
    - involvement in land use planning process
3. Identification of Well Construction, Abandonment, and Destruction Policies
    - water quality protection
    - manage vertical distribution of pumpage
4. Provisions to Update the Groundwater Management Plan

Primary Element 1 - Monitoring of Groundwater Levels, Quality, Production, and Subsidence

Prior to 1980, all water supply in the Upper Santa Clara River Area was developed from local groundwater; since 1980, imported surface water has become an increasing component of overall water supply in the area, but groundwater continues to meet all agricultural water demand and a significant part of municipal water demand. As a result of the long term development and use of groundwater in the area, there is a fairly substantial amount of historical groundwater level data, and a useful amount of groundwater quality data and groundwater pumping data that has been collected in the basin. All the available historical groundwater level, quality, and pumping data have been organized into a computerized data base for the Upper Santa Clara River Area. That data base, while separate, has been coordinated with an equivalent data base maintained by United Water Conservation District for the downstream basins on the Santa Clara River. The intent of database coordination has been to facilitate interpretation and reporting on groundwater and other water resource related issues by the respective agencies overlying the various basins along the river.

The networks of wells from which groundwater level and groundwater quality data have been collected are illustrated in Figures 5-1 and 5-2. The networks are comprised of a combination of active production wells, inactive production wells, and dedicated monitoring wells, shown on Figures 5-1 and 5-2. Data collection has historically varied from randomly infrequent to regularly scheduled but infrequent (e.g. semi-annual). The historical data collection efforts cannot be classified as an organized area-wide program of groundwater data collection, there are generally sufficient data available on which to interpret basin conditions. Ultimately, it is recognized that monitoring of existing wells, and expansion of the network of both production and monitoring wells, are key to accomplishing all the goals for the basin in this management plan. Monitored groundwater levels, quality, and pumping will collectively provide the basis for defining basin conditions and developing operational protocols that allow conjunctive use to support ongoing groundwater supply while avoiding undesirable conditions such as chronically depressed groundwater levels or degraded groundwater quality. Thus, a primary element of this plan is to develop and implement a groundwater monitoring program that is comprised of a network of wells, mostly as illustrated in Figures 5-1 and 5-2, but possibly expanded to include some dedicated monitoring wells as well as some potential new production wells. The frequencies and types of groundwater data collection will vary as a function of specific monitoring objectives in various parts of the basin. For initial implementation purposes , basin-wide groundwater monitoring protocols (locations and types of measurements, frequencies, etc.) are included in the Appendix to this Plan.

It should be noted, in light of the lack of historical subsidence and the low potential for it to occur as discussed in Section III above, that no formal subsidence monitoring is planned, i.e. no extensometers, fixed-point ground surveys or remote sensing. However, if the analysis of planned additional dry-year pumping indicates the potential for subsidence attributable to lower groundwater levels, monitoring or other appropriate action (e.g. re-distributed or reduced pumping) will be undertaken.

Primary Element 2 - Monitoring and Management of Surface Water Flows and Quality

The geologic and hydrologic configuration of the groundwater basin and the Santa Clara River system that overlies the aquifers in the basin is such that the River and the Alluvial aquifer can directly interact. Further, although the Saugus Formation has hydraulic characteristics that indicate it to be locally confined, groundwater can move between the Alluvium and the Saugus. The net result of the overall river-aquifer configuration is that groundwater is readily recharged

Figure 5-2
Water Quality Monitoring Network
Santa Clara River Valley East Groundwater Subbasin

by periodic natural surface water flows in parts of the basin, generally to the east of Bouquet Canyon; and groundwater discharges to the river in other parts of the basin, generally to the west of Bouquet Canyon. As a result of the latter groundwater discharges to the river, in combination with treated waste water discharges from the two local regional treatment plants, there is a significant surface water outflow from the basin in the Santa Clara River. That surface water flow to the west across the County line has increased over the last 20 years (Figure 5-3).

When considered in concert with the other elements of this groundwater management plan, a number of challenges related to surface water flow and quality are evident. First, knowledge of surface flow rates and quality, and variations in both, will be essential to incorporating surface water considerations into management of the interconnected aquifer system. Thus, monitoring of surface water flows and quality will be part of this plan; and the resultant data will be incorporated in the database of groundwater data that results from implementation of this element and Primary Element 1.

Secondly, continuation of some surface flow and non-degradation of surface water quality would appear to be appropriate objectives, particularly as recycled water use is integrated into the overall water supply in the basin, and as dry-year dependence on groundwater increases. Those issues have begun to be addressed in the MOU process with neighboring United Water Conservation District, as described in Primary Element 9 of this Plan, but they will be addressed on a more comprehensive basis as monitored data is collected, as a numerical groundwater flow model is developed and utilized (Primary Element 3), and as recycled water becomes part of the integrated water supply (Primary Element 7). Basin management of surface water flows and quality will also relate to potential groundwater management actions intended to augment yield, e.g. artificial groundwater recharge (Primary Elements 3 and 5), and groundwater management actions intended to preserve groundwater quality (Primary Element 6). For initial implementation purposes, surface water monitoring protocols (locations and types of measurements, frequencies, etc.) are included in the Appendix to this Plan.

In light of the preceding, this plan element is included in the overall groundwater management plan to address surface water flows and quality in concert with analysis and management of groundwater levels and quality. The implementation of this plan element will be essential to accomplishment of the fourth management objective (goal) for the basin.

Average of Daily Mean Streamflow over the Water Year
Santa Clara River at Los Angeles - Ventura County Line

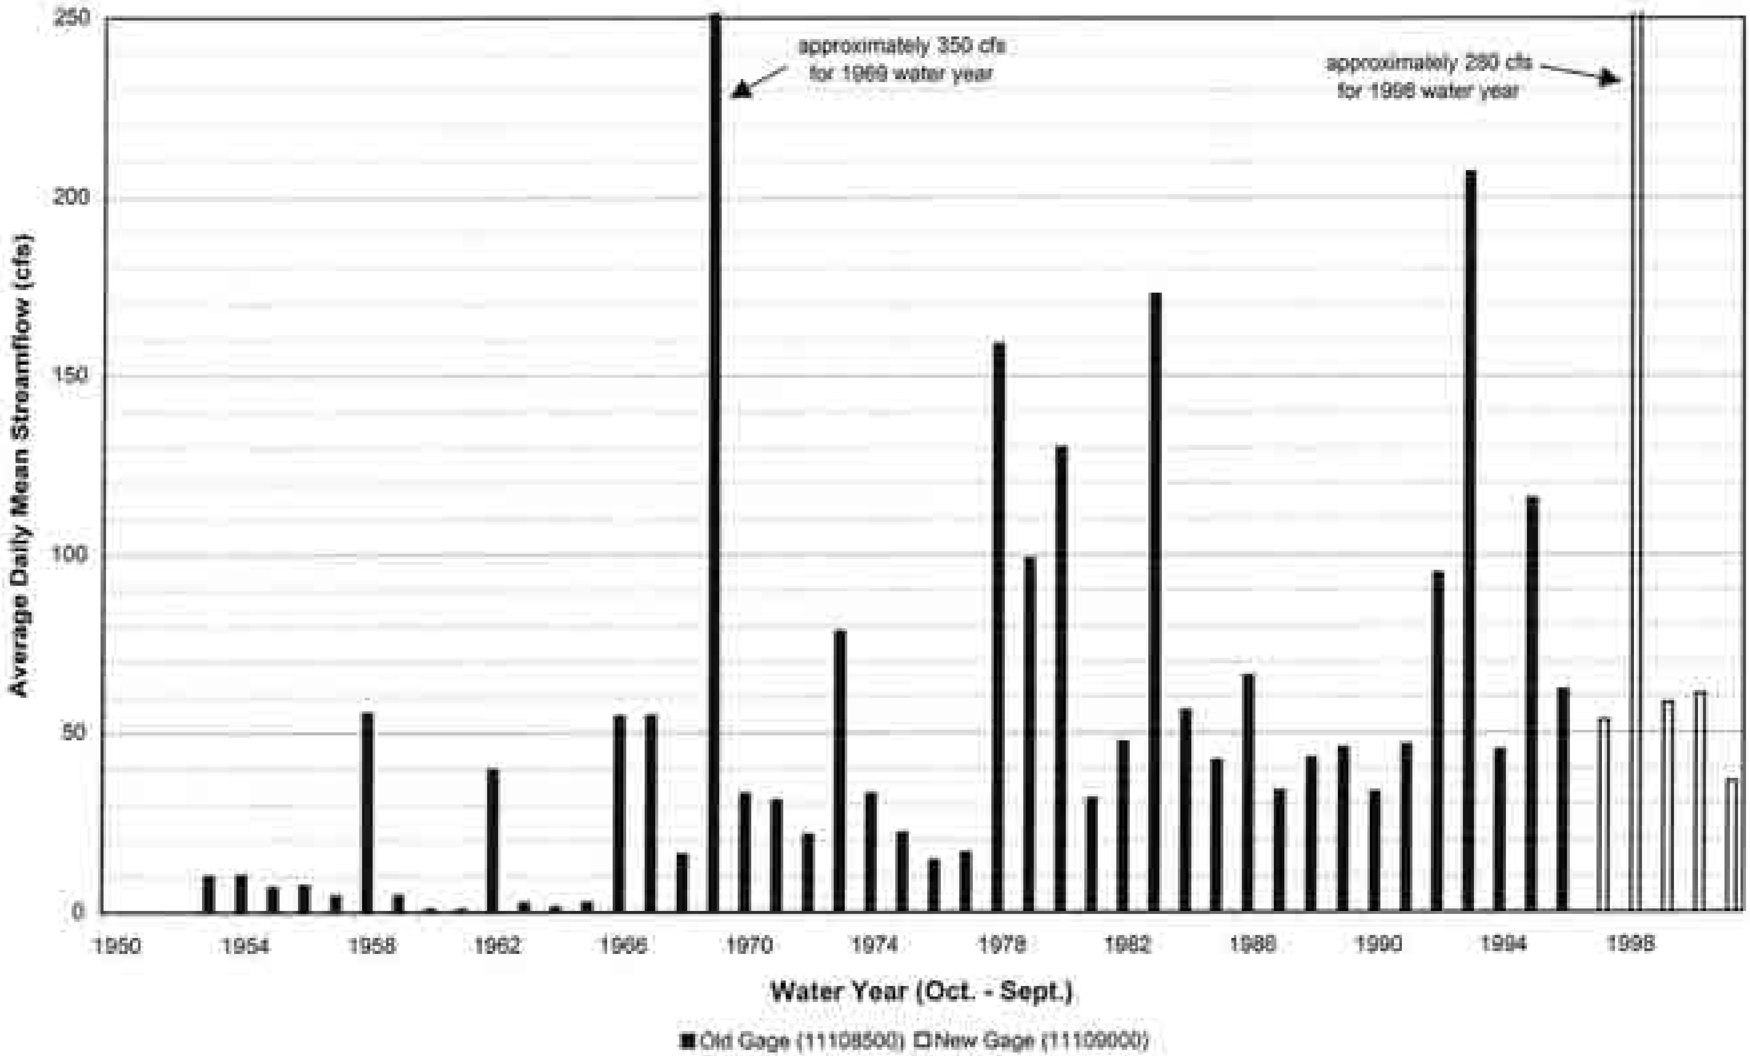

Figure 5-3

Primary Element 3 - Determination of Basin Yield and Avoidance of Overdraft

In order to accomplish all the goals for the basin, it will be essential to determine what yield can be developed on both a regular and an intermittent (dry period or emergency) basis. Such a determination of basin yield will be made to accomplish the main objective of operating within the yield of the groundwater basin, avoidance of overdraft.

On a long-term basis, there has not been any widespread, steady degradation of groundwater conditions that might be indicative of overdraft, i.e. decrease in groundwater levels or storage as a result of pumping in excess of the yield of the basin. There have been, and continue to be, short-term fluctuations in groundwater levels that are basically related to variations in local hydrological conditions, alternating increases and decreases in storage in response to wet and dry conditions (and associated fluctuations in recharge and pumping). Such fluctuations are typical of groundwater basin conditions in any conjunctive use setting, such as in this basin; groundwater is utilized from storage during dry years, or dry periods, and that storage is replenished during alternate wet years, or periods. The observation of these historical groundwater conditions, in combination with knowledge of pumpage from both the Alluvial and Saugus Aquifers, has led to current operational practices as well as general expectations regarding the approximate yield of the local groundwater system.

While historical operating experience, complemented by observed groundwater conditions, is an appropriate basis for generally planning for available groundwater supplies, it is possible and appropriate to more precisely analyze the basin to determine values or ranges of yield under varying hydrologic conditions, and to assess the impacts of various management actions that might be implemented in the basin. The MOU process described in Primary Element 9 of this Plan includes the development of a numerical groundwater flow model which is intended to be utilized for determination of the yield of the basin under existing land use and under existing groundwater and surface water development conditions. It is also expected to be used for implementation of this Plan Element to assess the yield of the basin under future land use conditions as well as future ranges of surface water importation, groundwater development, and recycled water use through varying hydrologic conditions, i.e. wet and dry periods that affect the availability of imported surface water.

The ultimate intent of this Plan Element is to develop an understanding and quantification of the yield of the basin, under varying hydrologic conditions and developing local cultural conditions, so that groundwater development and use can be managed in such a way to meet an appropriate fraction of total water demand while avoiding levels of groundwater use that would result in overdraft conditions. Thus, implementation of this Plan Element is essential to accomplishing the first and second management objectives (goals) for the basin.

Primary Element 4 - Development of Regular and Dry Year/Emergency Water Supply

The most recent updated Urban Water Management Plan (UWMP, December 2000) prepared by CLWA and the retail water purveyors in the basin (Newhall County Water District, Santa Clarita Water Company and Valencia Water Company) includes plans to develop 30,000 to 40,000 acre-feet per year (afy) from the Alluvial aquifer and 7,500 to 15,000 afy from the Saugus Formation in average/normal years. Both ranges of numbers are consistent with recent historical pumping that has not resulted in any indication of overdraft or other undesirable conditions. The UWMP also includes plans to slightly reduce Alluvial pumping in dry years (in recognition of historical experience with decreased groundwater levels in the eastern part of the basin during dry periods) to 30,000 to 35,000 afy, while potentially increasing dry-period Saugus pumping to 21,000 to 35,000 afy depending on the duration of dry conditions.

A major consideration in this plan is the accomplishing ~~of~~ this element in concert with Primary Element 3, i.e. development of both regular and dry year/emergency groundwater supply within the yield of the basin in order to avoid overdraft. Toward that goal, the model described in Primary Element 3 will be used to analyze projected results, i.e. groundwater levels, storage and stream flow impacts, in order to design the optimal distribution of pumpage or to refine the ranges of regular or dry period/emergency pumping volumes. The result will facilitate a water transmission and distribution design, and will also facilitate planning for supplemental water supplies and planning for proactive recharge activities to augment basin yield as necessary to meet water supply requirements. Thus, implementation of this Plan Element, within the confines of Primary Element 3, will be essential to accomplishment of the first management objective (goal) for the basin.

Primary Element 5 - Continuation of Conjunctive Use Operations

Beginning with the initial delivery of imported surface water from the State Water Project (SWP) in 1980, CLWA and the retail water purveyors in the basin have been practicing the conjunctive use of imported surface water and local groundwater. Conjunctive use in this setting has consisted of meeting water demands with a combination of imported surface water and local groundwater. Groundwater pumping has remained within a range that has not caused any evidence of overdraft, or associated undesirable impacts, and has fluctuated within that range to meet a larger fraction of water demand during periods of reduced surface water availability, such as at the end of the 1987-1992 drought and for several years immediately thereafter. Imported surface water use, on the other hand, progressively increased from 1980 through 1990, substantially decreased in the early 1990's due to extended drought conditions in Northern California, returned slowly to pre-drought levels over about a five year period, and has progressively increased again since 1996. The historical trend in water demand and the trends in groundwater and imported (SWP) surface water use to meet that demand are illustrated in Figure 5-4.

Conjunctive use of local groundwater and imported surface water will continue to be a key element in meeting all the goals for the basin, most notably utilizing groundwater for water supply without overdrafting the basin. Historical experience with groundwater pumping and aquifer response to varying hydrologic conditions has shown that the groundwater basin can support notable variations in pumping during wet and dry periods, but it cannot support continuous pumping at rates high enough to meet total local water demand. Thus, utilization of imported surface water in conjunction with local groundwater is essential to the management of groundwater for water supply without overdrafting that resource.

As part of conjunctively using surface water and groundwater, it is recognized that, particularly when the surface water supply is imported from the State Water Project, there will be variations in the amount of available surface water supply from year to year. Similarly, there are expected to be variations in local groundwater conditions as a function of local hydrologic conditions which affect, among other things, the natural recharge to the groundwater basin from year to year. In the case of this basin, local (Southern California) hydrology which affects local groundwater conditions may not necessarily be the same as the hydrology in a distant (i.e., northern California) location that directly affects the availability of supplemental, imported surface water in any given year. Thus, conjunctive use management is necessary to ensure that the groundwater basin is maintained to meet a regular component of water supply and to also provide a larger component of water supply during "dry periods" that affect supplemental surface water availability. Conjunctive use management is similarly important to ensure that local groundwater can be replenished, via reduced pumping and/or as a result of wetter local

hydrologic conditions, during periods of wet/normal surface water availability. In light of all the preceding, implementation of this Plan Element is essential to accomplishing all the management objectives (goals) for the basin.

Primary Element 6 - Long Term Salinity Management

In general, groundwater quality in the basin is such that groundwater supplies meet standards for beneficial use in the basin, most of which is for municipal (domestic) use but some of which remains for agricultural and some other irrigation (non-domestic) use. There also have been no notable historical trends of groundwater quality degradation in the basin over time. However, a number of geologic and hydrologic factors suggest that observations and interpretation of groundwater quality warrant attention to ensure long-term preservation of groundwater quality. Notable among those geologic and hydrologic factors are: 1) the largely "closed" geologic nature of the aquifer system at the western limit of the basin (other than a thin section of Alluvium beneath the Santa Clara River, there is no continuity of aquifer materials between the Santa Clara River Valley East groundwater subbasin and the next downstream groundwater basin on the Santa Clara River, the Piru Basin in Ventura County); 2) the predominant groundwater flow direction in the basin toward the west, where there is the lack of continuity of aquifer materials for groundwater outflow; 3) a certain amount of rising groundwater discharge into the Santa Clara River; and 4) an increasing discharge of treated waste water into the Santa Clara River toward the western end of the basin which, when accounting for the planned use of a substantial amount of recycled water in the Basin (Primary Element 7) will result in higher salt concentrations than other sources of water supply in the Basin. The combination of the preceding factors suggests that, on a long-term basis, there could be an accumulation of dissolved minerals in the aquifer system if salinity is not managed in a way to avoid undesirable groundwater quality degradation. Consequently, this primary element is included in the overall groundwater management plan to include the interpretation of groundwater quality data (Primary Element 1) and to incorporate groundwater quality as an important consideration in the implementation of the other elements of the plan, most notably Continuation of Conjunctive Use Operations (Primary Element 5), Integration of Recycled Water (Primary Element 7), and Identification and Cleanup of Contaminated Groundwater (Primary Element 8). The Long Term Salinity Management element of the plan is essential to accomplishing the third management objective (goal) of preserving groundwater quality in the basin.

Primary Element 7 - Integration of Recycled Water

In 1993, CLWA prepared a Reclaimed Water System Master Plan that outlined a multi-phase program to deliver highly treated, recycled water in the Valley. At that time, potential recycled water uses in excess of 10,000 afy, of which about 9,000 afy were located within the CLWA service area, were identified. The first phase of the Reclaimed Water System Master Plan to deliver 1,700 afy has been environmentally reviewed and is being implemented, with initial deliveries having commenced in August 2003.

The 1993 recycled water plan expected to reclaim up to 10,000 afy. CLWA has been updating that plan to ultimately provide up to about 17,000 afy for irrigation and other non-potable uses. It has also been recognized that, if the Newhall Ranch project is approved, total annual demands for recycled water in the area could ultimately approach 20,000 afy.

This plan element is included in the groundwater management plan primarily because recycled water use in the Valley will supplant a substantial fraction of fresh water demand that would otherwise be met with potable water from some combination of pumped groundwater and imported surface (SWP) water. With total municipal, agricultural and other water demands projected to increase from about 75,000 afy at present to slightly more than 100,000 afy by 2020, the progressive increase in recycled water use from 1,700 afy to as much as 17,000 to 20,000 afy, recycled water use would reduce demands on potable sources (groundwater and imported SWP water) by up to nearly 20 percent. Accomplishment of this Plan Element will benefit the accomplishment of Elements 3 and 4, and will also contribute to the accomplishment of all four of the Basin Goals.

Primary Element 8 - Identification and Mitigation of Soil and Groundwater Contamination

As in numerous other groundwater basins in California, there have been a number of leaking underground storage tanks or other similar situations which have released organic constituents into soil, and possibly into groundwater, in the basin. None of those has impacted municipal or other water supply wells and, consequently, there has been no adverse impact on groundwater supply in municipal or other water supply systems in the basin. However, the detection of perchlorate in the discharge from four Saugus wells (CLWA Santa Clarita Water Division Saugus Wells 1 and 2, Newhall County Water District Well 11, and Valencia Water Company Well 157) in 1997, followed by the detection of perchlorate in one Alluvial well (CLWA Santa Clarita Water Division Stadium Well) in 2002, has led to the inactivation of all those wells.

They remain out of municipal water supply service to date.

Experts retained by CLWA have opined that the cause of perchlorate contamination in the Saugus Formation is former operations associated with munitions manufacturing on property formerly owned by Whittaker-Bermite Corporation, which is immediately adjacent to all the impacted wells. Investigation and characterization of the perchlorate contamination, and initiation of control and cleanup are ongoing; however, remediation actions have not yet commenced. Consequently, the municipal water purveyors continue to be impacted by the loss of water supply capacity of the impacted wells. Associated with that loss is a concern about the migration of perchlorate contamination in a generally downgradient direction, toward other active wells completed in the Saugus Formation and the Alluvium and toward other potential well sites. In light of both the inactivation of wells and the potential downgradient impact on the aquifers, CLWA and the other retail water purveyors had initiated both legal action against responsible parties and technical investigation of the contamination. Recently the parties have entered into an interim settlement agreement which is intended to complete investigation and characterization of the contamination in a collaborative effort. This effort will facilitate and expedite remediation actions.

The primary purpose for technical investigation of the perchlorate contamination by CLWA and the other municipal purveyors is to ultimately recover the currently unavailable water supply capacity that has resulted from the inactivation of impacted wells. Conceptually, that may be accomplished by some combination of reactivation of impacted wells and new well construction. CLWA has joined with the U.S. Army Corps of Engineers in a study to develop information about the contamination. CLWA and the retail water purveyors have also independently commissioned an assessment to conclude what treatment technology is appropriate for removal of perchlorate from pumped groundwater; they have also independently commissioned the application of a numerical groundwater flow and quality model to determine an optimal pumping program for 1) perchlorate removal from the aquifer, 2) control of its migration in the aquifer, and 3) restoration of impacted pumping capacity for water supply. With data derived from that work, CLWA and the other purveyors are preparing to submit an application to the State Department of Health Services, by late 2004, for a permit to return to pumping from the locally impaired Saugus Formation. The proposed pumping would be combined with approved wellhead treatment to render the treated water suitable for municipal supply. In addition to the latter objective to recover currently inactivated water supply, the proposed pumping would be designed and operated to remove contaminated groundwater and to control any further migration of contaminated groundwater toward other Saugus wells to the west. CLWA and the retail water purveyors then expect to be able to design and implement, alone or in concert with responsible parties, a contamination control and treatment program at or near their impacted wells that can, in part, make groundwater available for municipal or other beneficial use. They also expect that such a program will provide some hydraulic and associated water quality protection for other parts of the aquifer system to keep contamination from impacting other wells or other parts of the aquifers in which water supply wells might be completed.

Regarding the balance of the aquifer system, water supply planning to date (i.e. the current Urban Water Management Plan) includes expanded development of the Saugus Formation for dry-period and emergency water supply. Data development and control and treatment of groundwater contamination in the Saugus Formation will be critical to accomplishing that water supply plan. In terms of this groundwater management plan, accomplishment of this plan element will contribute to the accomplishment of all four management objectives (goals) for the basin.

Primary Element 9 - Development and Continuation of Local, State and Federal Agency Relationships

As the local SWP contractor, CLWA has long-established working relationships with local and state agencies that will continue on an ongoing basis. By nature of its primary function, CLWA will continue to interact with state agencies, most notably the Department of Water Resources, on the operation of the State Water Project. The latter, of course, has been the source of supplemental imported surface water that has made the initiation and continuation of conjunctive use operations possible since 1980. It will also be the primary component, with local groundwater, in continuation of conjunctive use operations in the future (Primary Element 5 of this Plan).

CLWA is the treated surface water provider to all the retail water purveyors, including Newhall County Water District, Los Angeles County Waterworks District No. 36, Valencia Water Company, and its own Santa Clarita Water Division. CLWA has a historical and ongoing working relationship with all those local agencies, as well as with other local groundwater pumpers, to manage water supplies to effectively meet water demands within the available yields of imported surface water and local groundwater. In fact, the Advisory Council convened to assist in the preparation of this Plan is comprised representatives of all the local water purveyors and significant groundwater pumpers.

A local Memorandum of Understanding (MOU) process among CLWA, other purveyors within CLWA's service area, and United Water Conservation District (UWCD) in neighboring Ventura County is a classic illustration of a local agency relationship that has produced the beginnings of local groundwater management, now embodied in this comprehensive plan, most notably in Primary Elements 1 through 5. In 2001, out of a willingness to seek opportunities to work together and develop programs that mutually benefit the region as well as their individual communities, those agencies prepared and executed the MOU that initiated a collaborative and integrated approach to several of the aspects of water resource management that are now included in this Plan. UWCD manages surface water and groundwater resources in seven groundwater basins, all located in Ventura County, downstream of the East Subbasin of the Santa Clara River Valley that is the focus of this Plan. United is thus a logical partner in the cooperation of management efforts to accomplish the objectives (goals) for this basin, particularly as they relate to preservation of surface water resources that flow through the respective basins. As a result of that MOU, the cooperating agencies have integrated their database management efforts (part of Primary Elements 1 and 2 of this Plan), have initiated the development of a numerical groundwater flow model (for utilization in Primary Elements 3, 4 and 5 of this Plan), and are continuing to prepare reports on the status of basin conditions, as well as on geologic and hydrologic aspects of the overall stream-aquifer system.

A local extension of the interaction among CLWA, the retail water purveyors, and UWCD is an ongoing working relationship with the City of Santa Clarita. CLWA and the retail water purveyors meet regularly with City staff and also present water supply conditions via study sessions with the City Council on a routine basis. It is expected that the implementation of this Plan will result in the availability of a broader range of information transfer with the City relative to the existing and future water supply to its residents. An additional expectation of this Plan with respect to the relationship among CLWA, the retail water purveyors, and the City is the intent of CLWA and the purveyors to provide input to the City as a reviewer of proposed development relative to any potential contamination of groundwater associated with such proposed development. CLWA provides input to the City, as suggested in Water Code Section 10753.8, via review of land use plans and coordination with the City Planning Department to identify and assess any development-related activities which might pose a risk of groundwater contamination. By expressing this expectation of its groundwater management plan, CLWA is not intending to insert itself into the jurisdiction or authorization of any other land use permitting agency; rather, CLWA is intending to provide review and input to the land use permitting process to protect the groundwater supply against any potential contamination that might occur as a result of any given development project.

This Primary Element is included in this Plan to formalize the historical local and state agency working relationships as part of comprehensively managing local groundwater, in concert with imported surface water and local recycled water, to accomplish all the management objectives (goals) for the basin.

Primary Element 10 - Groundwater Management Reports

As briefly described in the Introduction of this Plan, local groundwater management planning already includes, among several other activities, analysis of groundwater conditions and preparation of annual reports on groundwater and all other aspects of water resources and water supplies in the Santa Clara River Valley East groundwater basin. In addition, recently formalized cooperative work with neighboring UWCD includes both regular reporting on the status of groundwater conditions and specific reporting on geologic and hydrologic aspects of the overall stream-aquifer system. For example, documentation of the numerical groundwater modeling work currently in progress is expected to be the first of the latter reports in the next year.

Beginning in 1998, CLWA and the retail water purveyors in the basin have prepared a series of annual reports, known locally as the Santa Clarita Valley Water Report, to describe all aspects of water supply and water resource conditions in the basin. That report provides current information to local City and County land use agencies, and to other interested parties, about current water requirements, use of groundwater and treated imported surface water to meet those water requirements, groundwater conditions (pumping, groundwater levels and quality, etc.), local surface water conditions, the status of imported surface water supplies including details of delivered SWP water in the reported year as well as an up-to-date summary of available imported SWP water for the next year, a short-term projection of water requirements in the next year, and other appropriate details about water requirements and supplies such as, for example, the status of introducing recycled water as a component of non-potable water supply.

In light of the frequency and comprehensive nature of the annual Water Reports, and also in light of the planned preparation of more detailed technical reports on various aspects of the basin as appropriate, the continued preparation of those reports will serve as regular and *complete reporting on all aspects of this groundwater management plan.*

Secondary Element 1 - Continuation of Public Education and Water Conservation Programs

CLWA has provided water conservation and public education programs that will continue and will be expanded as a complement to and an element of this groundwater management plan. The expansion of water conservation will largely stem from CLWA's having signed the "Memorandum of Understanding Regarding Water Conservation in California" (Urban MOU) in 2001, which made CLWA a wholesaler member of the California Urban Water Conservation Council. CLWA has thus committed to implementation of cost-effective water conservation measures known as Best Management Practices (BMPs) that are included in the Urban MOU and are intended to reduce California's long-term urban water demands. The BMPs have been incorporated into the water demand management measures section of the Urban Water Management Planning Act.

Water conservation and related public education measures have generally been developed in California to achieve the following goals:

- meet legal mandates
- reduce average annual potable water demands
- reduce sewer flows
- reduce water demands during peak seasons
- meet drought restrictions.

As a wholesaler of imported surface water CLWA has implemented the following BMPs for several years prior to signing the MOU:

- distribution system water audits, leak detection and repair
- public information
- school education
- wholesale agency assistance
- conservation pricing
- conservation coordinator.

As a signatory to the MOU, CLWA's water conservation and public education program will expand to include the following BMPs found to be locally cost-effective, as detailed in the 2000 Urban Water Management Plan for CLWA and the Santa Clarita Valley retail purveyors.

- water survey programs for single-family residential and multi-family residential programs
- residential plumbing retrofits
- metering with commodity rates for all new connections and retrofit of existing connections
- large landscape conservation programs and incentives
- high-efficiency washing machine rebate programs (when also provided by local energy providers or wastewater utilities)
- conservation programs for commercial, industrial, and institutional accounts
- wholesale agency programs to financially or otherwise support water conservation efforts by retailers (this measure will be expanded)
- residential ultra-low-flow toilet replacement program.

This Secondary Element, while identical to independent CLWA efforts in water conservation and public education, is incorporated in this Plan to complement other Plan elements, and to move toward accomplishment of all management objectives (goals) for the groundwater basin.

Secondary Element 2 - Identification and Management of Recharge Areas and Wellhead Protection Areas

The 1986 Amendments to the federal Safe Drinking Water Act (SDWA) established a new Wellhead Protection Program (WPP) to protect groundwater that supplies drinking water wells for public water systems. Each state was required to prepare a WPP and submit it to the USEPA by June 19, 1989. However, California did not develop an active state-wide Wellhead Protection Program at that time. Subsequently, in 1996, reauthorization of the SDWA established a related program called the Source Water Assessment Program. In 1999, the California Department of Health Services (DHS) Division of Drinking Water and Environmental Management developed its Drinking Water Source Assessment Program (DWSAP), and EPA approved it. The overall objective of the DWSAP is to ensure that the quality of drinking water sources is protected.

As discussed in Section 1 of this Plan, the potential groundwater management plan component "identification and management of wellhead protection areas and recharge areas" is stated, even in the most recently amended version of Water Code Section 10753.8, as one that "may" be included. However, the wellhead protection aspect of this component, which was optional when AB 3030 was adopted, is now essentially required as a result of the 1996 SDWA reauthorization. In California, the DWSAP satisfies the mandates of both the 1986 and 1996 SDWA amendments. The California DWSAP includes delineation of the areas (i.e., protection areas or Groundwater Protection Zones) surrounding an existing or proposed drinking water source where contaminants have the potential to migrate and reach that source. The program includes preparation of an inventory of activities that may lead to the release of contaminants within these zones. The activities, referred to in the DWSAP as Potentially Contaminating Activities, include such land uses as gas stations and dry cleaners, as well as many other land uses. The activities also include known contaminant plumes regulated by local, state, and federal agencies. The zones, which are calculated based on local hydrogeological conditions and also well operation and construction parameters, represent the approximate area from which groundwater may be withdrawn during 2, 5, and 10 year time periods. These zones also represent the area in which contaminants released to groundwater could migrate and potentially affect the groundwater extracted by wells located within the designated zones. The DWSAP assessment also includes a risk or vulnerability ranking based on a combined numerical score that results from points assigned to various evaluations conducted as part of the DWSAP process. This ranking provides a relative indication of the potential susceptibility of drinking water sources to contamination.

Although DHS is responsible for conducting drinking water source assessments for systems existing prior to the adoption of the California program, DHS has encouraged purveyors to perform their own assessments. Assessments for existing systems were due at the end of 2002; however, DHS received an extension allowing its assessment work to be completed by May 2003. Permitting of a new water supply well requires that a DWSAP be completed as part of the permit process, and this is responsibility of the applicant. Within CLWA, DWSAP assessments have been completed for the three municipal water purveyors who utilize groundwater for some of their water supply, including 15 for the CLWA Santa Clarita Water Division, 20 for Valencia Water Company, and 13 for Newhall County Water District.

The results of the DWSAPs can be used as a planning tool to guide land use development in the vicinity of water sources. The DWSAPs prepared for water sources in the basin should, in some fashion, be reviewed every five years and updated more frequently as appropriate. The collective DWSAP information can also be integrated with other management activities (e.g., the geographical position of potential or existing contaminating activities can be incorporated in the monitoring program database; plume extents, as available, can be graphically displayed by aquifer and isoconcentrations) to aid siting of new wells, particularly when contaminant migration problems are also evaluated with respect to local hydrogeological conditions and the potential influence of nearby wells on plume migration.

In addition to the wellhead protection program that is focused on wells that are sources of drinking water, a broader aspect of this Plan Element is protection of the overall recharge areas of the aquifer system in the basin. As discussed in Section III, the most developed aquifer, the Alluvium, has experienced historical fluctuations in groundwater levels in the eastern portion of the basin, but has had essentially constant groundwater levels in the western portion of the basin. The characteristic difference between the two portions of the basin, generally divided at the confluence of the Santa Clara River and its Bouquet Canyon tributary, is the perennial flow in the Santa Clara River to the west of that location versus the intermittent flow in the river to the east. The intermittent fluctuations in groundwater levels east of Bouquet Canyon are indicative of rapid response, i.e. recharge, from streamflow when it is present. Similarly, the relatively constant groundwater levels west of Bouquet Canyon are indicative of ongoing response, i.e. recharge, from the perennial flow in the river. In light of those conditions, part of this Plan Element is intended to protect the overall channel system of the Santa Clara River and its tributary system, notably where they overlie Alluvial aquifer materials of significant extent. Protection in this case is intended to mean preservation of the infiltration capacity of the stream channel so that both intermittent and perennial flows can continue to recharge the aquifer as has historically occurred.

Finally, with regard to protection of recharge areas, it is expected that additional exploration and development of the Saugus Formation, for additional water supply as described in this Plan, will lead to further understanding of the locations and mechanisms for recharge of that aquifer, which is exposed at the surface throughout much of the area of this Plan. As that understanding evolves, part of this Plan Element will be to identify means of ensuring that significant portions of Saugus recharge are not compromised by land development activities.

This Plan Element is included to incorporate the DWSAP efforts and the overall protection of groundwater recharge into the local groundwater management plan. Completion of DWSAP efforts to comply with state DHS requirements and preservation of overall aquifer recharge are key parts of accomplishing the first and third management objectives (goals) for the basin.

Secondary Element 3 - Identification of Well Construction, Abandonment, and Destruction Policies

Well construction permitting in the basin is administered by the Los Angeles County Health Department, which effectively implements the State Well Standards for water wells, monitoring wells, and cathodic protection wells. Permitting of municipal supply wells is also within the purview of the State Department of Health Services. One goal of this management plan for the area, protection and preservation of groundwater quality requires that all wells be properly constructed and maintained during their operational lives, and properly destroyed after their useful lives, so that they not adversely affect groundwater quality by, for example, serving as conduits for movement of contaminants from the ground surface and/or from a poor quality aquifer to one of good quality. Toward that end, this element is included in the overall plan to support well construction and destruction policies, and to participate in their implementation in the Basin, particularly with regard to surface and inter-aquifer well sealing and proper well destruction, which are critical in the management of a multiple aquifer system that has some connection with the Santa Clara River and its tributaries.

Secondary Element 4 - Provisions to Update the Groundwater Management Plan

The primary and secondary elements of this local area groundwater management plan reflect the current understanding of the occurrence of groundwater in the Santa Clara River East Valley groundwater subbasin, and specific problems or areas of concern about that resource. Those management elements are designed to achieve specified goals to develop local groundwater for regular and dry year/emergency water supply while protecting and preserving groundwater quantity and quality for overlying beneficial use into the foreseeable future, and while also protecting and preserving valuable surface water resources that are directly related or connected to groundwater. While the groundwater management plan provides a framework for present and future actions, new data will be developed as a result of implementing the plan. That new data could define conditions which will require modifications to currently definable management actions. As a result, this plan is intended to be a flexible document which will be reviewed and updated to modify existing elements and/or incorporate new elements as appropriate in order to recognize and respond to future groundwater and surface water conditions. Although not intended to be a rigid schedule, review and updating of this plan will initially be conducted in five years, with subsequent future updates scheduled as appropriate at that time. In accordance with Primary Element 10, the retail purveyors and CLWA will continue to produce the Santa

Clarita Valley Water Report on an annual basis. Data and information from these reports will be compiled and utilized as part of the review and updating of this plan.

Appendix I

Groundwater and Surface Water Monitoring Protocols

The CLWA Groundwater Management Plan includes two Elements (Primary Elements 1 and 2) that relate directly to ongoing, and expanded as appropriate, monitoring of key hydrologic quantities associated with the implementation of the Plan. Notable among the data to be collected are groundwater levels, groundwater quality, pumpage from water supply wells, and surface water flows and quality. Other hydrologic data such as precipitation are intended to be measured and maintained in accordance with the standards in place for the respective precipitation gage stations in the Valley; consequently, this Appendix does not address the specific establishment of protocols for precipitation gaging. On another matter of hydrologic data, land subsidence, the Plan discusses the low probability for subsidence in the Valley, particularly as related to historical groundwater pumping from both the Alluvial and Saugus Formation aquifers. Consequently, the Appendix does not address the establishment of protocols for measuring land subsidence. As noted in the Plan, if future analysis of increased pumping from the Saugus Formation, as currently planned, suggests changes in groundwater levels that might be conducive to inelastic subsidence, the need for subsidence monitoring will be reconsidered at that time; and some combination of land surface elevation surveying, remote sensing of land surface deformation, and measurement of earth consolidation via extensometers would be considered as part of establishing protocols for monitoring subsidence.

Groundwater Monitoring

For purposes of Plan implementation, the most essential groundwater-related data are water levels, water quality, and pumpage. Consequently, the following discussion of monitoring protocols focuses on those hydrologic parameters.

Groundwater Levels - The distribution and frequency of current groundwater level measurements in Alluvial wells and in Saugus Formation wells are illustrated in Figures A1 and A2, respectively. Tables A1, A1a and A2 show the dates that groundwater level measurements were made in Alluvial and Saugus Formation wells. As discussed in the Plan, for the Alluvium, the distribution of monitoring is sufficient to interpret water level and groundwater storage trends. Thus, it is intended that the fundamental distribution and frequency of Alluvial groundwater level measurements remain generally as illustrated in Figure A1: general semi-annual measurements complemented by some quarterly measurements disbursed throughout the Alluvial aquifer. The only exception to the preceding intention is in the western-most portion of the Alluvium, where agricultural pumping remains the water supply objective and water level measurements are primarily annual. In part to conform to the balance of Alluvial groundwater level measurements, and more importantly to monitor stream-aquifer connection near the western, or downgradient, end of the Alluvium in the basin, it is the intent of Plan implementation to increase that water level monitoring to semi-annual to quarterly frequency.

In the Saugus Formation, the distribution of groundwater level measurements is limited by the number and location of wells; the locations in Figure A2 reflect where the Saugus has been developed for water supply. Ultimately, as future exploration and development of the Saugus expand, it is expected that the distribution of groundwater level measurements will expand to those future well locations. For Plan implementation purposes, the existing monthly frequency of water level monitoring is intended to continue.

Water level measurement methodology, which is dominated by utilization of electric sounders, is expected to remain largely unchanged. Some calibrated airlines and possibly some dedicated electro-hydraulic transducers are expected to complement electric sounders in certain wells. All those water level measurement methods are sufficiently accurate to satisfy the needs to which the resultant data is to be put.

Groundwater Quality - The distribution and frequency of current groundwater quality monitoring in Alluvial wells and in Saugus Formation wells are illustrated in Figures A3 and A4, respectively. Tables A3 and A4 show the dates that groundwater quality (total dissolved solids) was monitored in Alluvial and Saugus wells. For the most part, the distribution and frequency of water quality sampling are sufficient to interpret general quality trends. One notable constraint in the Alluvium, however, is the discontinuation of water quality data collection in some wells since 1988, mostly toward the western, or downgradient, end of the basin. In order to restore an ongoing historical record, part of Plan implementation will be to attempt to re-establish regular, i.e. yearly to triennial, water quality sampling and analyses in those wells with some form of historical water quality record. In the same vein, part of Plan implementation will include selection of a number of wells in key locations, e.g. near the mouths of canyons, for semi-annual analysis of indicator parameters as a basis for assessing seasonal or other variations in groundwater quality.

Finally with regard to groundwater quality, the spatial limitations on Saugus water quality data are comparable to the limitations related to Saugus groundwater levels, but as a result of the limited, localized development of the Saugus for water supply. While the regular monitoring of quality will continue via Plan implementation, the expansion of Saugus water quality data is expected to follow the expanded exploration and development of that aquifer as described for groundwater levels above.

Production (Pumpage) - The great majority of water supply wells in the basin are now dedicated to municipal supply; consequently, those wells are equipped with production meters which allow direct monitoring of pumpage on any desired frequency, e.g. instantaneous flow rate, or cumulative volumes on a daily, monthly, or other frequency. A few wells remain dedicated to agricultural water supply, and those wells are not equipped with flow meters. However, long-standing practice at all those wells has been to meter power consumption for each well and to combine that data with the results of annual pump performance testing in order to indirectly compute approximate pumpage from each agricultural well. That methodology is sufficiently accurate for ongoing documentation of pumpage and interpretation of basin response to pumping; it is also sufficiently accurate for groundwater flow model input as part of assessing basin yield, all as part of this Plan. Consequently, implementation of this Plan includes regular reading of flow meters on municipal supply wells and continued indirect computation of agricultural pumpage from the remaining agricultural water supply wells in the basin.

Surface Water Monitoring

Part of Plan implementation is the development of a surface water quality monitoring network. Of particular concern is establishing a surface water quality data set that, combined with groundwater data, will allow for a more detailed analysis of stream-aquifer interactions. The data of primary interest for this and other Plan purposes are surface water flow and surface water quality, discussed below.

Surface Water Flow - The existing surface water flow monitoring network within the basin consists of stream flow gaging stations along the Santa Clara River and its tributaries, and measurements of discharge to the River from the Saugus and Valencia Water Reclamation Plants. Monitoring of stream flow gages along the River and its tributaries has been mostly sporadic and limited to times prior to 1977, although measurements at some gages resumed in 2002. One exception is the gage at the Los Angeles-Ventura County line, where the daily mean stream flow was monitored from 1953 to 1996; the gage was replaced with one downstream near Piru in 1996. The Los Angeles County Sanitation Districts monitors the average discharge flow of treated wastewater from the Saugus and Valencia Water Reclamation Plants to the Santa Clara River.

Plan implementation will include evaluating the distribution, future accessibility and configuration of the existing stream flow gaging stations to determine if they will be suitable for inclusion in the ongoing surface water flow monitoring network. Plan implementation will further include installation and operation of gage station modifications, as well as installation and operation of additional dedicated gaging stations as determined to be required.

Surface Water Quality - Surface water quality has been analyzed at many locations along the Santa Clara River and its tributaries but, with few exceptions, the data is limited to several measurements at each location. Water quality in the Santa Clara River at the Los Angeles-Ventura County line was analyzed on a semi-annual basis from 1951 to 1988, and is currently measured quarterly by United Water Conservation District. Since 2002, the Los Angeles County Department of Public Works has monitored water quality in the Santa Clara River near Interstate 5 during four wet weather events and at two other times each year to comply with the requirements of a National Pollution Discharge Elimination System (NPDES) permit that covers the County and 84 incorporated cities. The Saugus and Valencia Water Reclamation Plants also monitor the quality of the treated wastewater they discharge to the Santa Clara River as part of compliance with the requirements of their NPDES permits.

Plan implementation will include identifying key locations for future surface water quality monitoring, identification of constituents of concern and monitoring frequency for each location, and implementation of appropriate sampling and analytical methodology at the selected key sites.

Groundwater Management Plan
Public Comments

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
UWCD #5	Under Primary Element 2 related to surface flows, in addition to SWP water contributing to the increased flow of the Santa Clara River, other considerations should be noted (hydrologic cycle, Alluvial pumping).	Primary Element 2	As noted above, discussion of groundwater related conditions is included in the Plan as a frame of reference for the Plan objectives and elements. Future interpretation and reporting will take such details as the impacts of the hydrologic cycle and Alluvial pumping into account.
Santa Clarita Organization for Planning and the Environment #1	Extensive pumping and lack of protection of recharge areas have resulted in almost complete elimination of surface flows and summer ponding necessary to wildlife as well as causing water level drops in wells that have resulted in water quality and availability problems for small users.	Section III (Groundwater Levels and Storage) and (Groundwater Quality) and Primary Elements 1, 2 and 3	See responses to SCOPE Comments 5, 6 and 9, Sand Canyon Comments 1 and 7, and Sierra Club Comment 3 regarding pumping within basin yield, avoidance of overdraft, preservation of recharge areas, and consideration of riparian conditions.
SCOPE #2	Concern that environmental organizations, small well owners, City of Santa Clarita, LA County, and others were not included on the Advisory Board.	Water Code Appendix § 103 15.1(c)(2)	CLWA legal counsel has confirmed that CLWA complied with the requirements of AB 134 regarding the composition of the Advisory Council. LA County was represented by LA Co. WWD #36 and LA County Sheriff's Department.
SCOPE #3	The GWMP should include a timeline for completion of the plan components.	AB 3030[2] and AB 134[3]	AB 3030 and AB 134 do not require the inclusion of a timeline.
SCOPE #4	The GWMP is lacking in the review of land use plans and coordination with land use agencies. Land use issues should be given higher priority. This may include a wellhead protection plan.	Water Code § 10753.8(f), Primary Element 9 and Secondary Element 2	Primary Element 9 and Secondary Element 2 have been expanded to further address general preservation of recharge areas and appropriate review of land use plans to protect against potential groundwater contamination.
SCOPE #5	GWMP should address maintaining tributaries in a natural state to enhance water recharge and quality.	This is not explicitly required by AB 3030 but does relate to Secondary Element 2	Secondary Element 2 has been expanded to address preservation of in-channel recharge areas in both the Santa Clara River and its tributaries.

[3] Stats. 2001, Ch. 929.

C:\Documents and Settings\...\Local Settings\Temporary Internet Files\OLK...\GWMP COMMENTS TABLE ... .doc

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[5]	RESPONSE
SCOPE #6	GWMP should find ways to increase water recharge. Water agencies should also coordinate to prevent paving of prime recharge areas.	This is not explicitly required by AB 3030 but relates to Primary Elements 3, 4 and 5 and Secondary Element 2.	Potentially increasing groundwater recharge will be part of Primary Elements 3, 4 and 5. Prevention of paving prime recharge areas is included in the expanded Secondary Element 2.
SCOPE #7	Number One Goal should not be "Development of Local Groundwater for Water Supply" because groundwater has many other important uses (recreational, biological, etc…)	This is not required by AB 3030 or AB 134. See Section II of GWMP.	The text of Section II, Management Objectives (Goals) for the Basin does not indicate a preference of any one objective over the others. The listing is not intended to indicate that any objective will not be attempted; all objectives are intended to be achieved.
SCOPE #8	Agricultural water usage in the GWMP is overestimated with the perennial yield (40,000 afy) estimate higher than that in a Richard Slade report, less agricultural runoff water is available for recharge today.	Section IV (Existing and Projected Water Supplies)	Reported historical agricultural pumping is consistent with all available records. A perennial yield of 40,000 afy is not included or implied in the GWMP. Rather, estimated ranges of 30,000 to 40,000 afy, depending on hydrologic conditions, are included as expected yield from the Alluvium. That range is consistent with historical reports, and with observations of actual Alluvial aquifer response to pumping in that range for at least the last 50 years.
SCOPE #9	Disappearance of year round Santa Clara River flow is indication of overdraft. "There are numerous records and observations by long-time residents indicating that surface flow usually occurred year round."	Section III (Areas of Concern and Identified Problems), Water Code § 10753.8(c).	Disappearance of year round stream flow does not necessarily indicate groundwater overdraft. In fact, stream flow west of Bouquet Canyon is now perennial. Part of implementing Primary Element 1 will be to obtain the "numerous records" of year round stream flow that are noted to have actually occurred.
SCOPE #10	GWMP should disclose the reduction in production capability because of perchlorate contamination.	Primary Element 8, § 10753.8(j).	The GWMP notes the inactivation of wells that have been impacted by perchlorate contamination.
Sand Canyon Area Well Owners Assoc. #1	Groundwater is extensively pumped and recharge areas are not adequately protected; water level in four wells has dropped from 12 ft in 1997 to 93 ft currently.	This relates to Primary Elements 1 and 3, and Secondary Element 2.	The noted groundwater level fluctuations are consistent with those described in Section III and illustrated in Figure 3-2 for the Sand Canyon area. Section III also describes and illustrates the historical recovery from such declines. Avoidance of overdraft, i.e. continuous lowering of water levels, and protection of recharge areas are included in Primary Element 3 and Secondary Element 2, respectively.

C:\Documents and Settings\...\GWMP COMMENT MATRIX REVISED ... .doc

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Sand Canyon #2	Advisory board lacks representation by rural well owners.	Water Code Appendix § 103-15.1(e)(2)	CLWA complied with the requirements of AB 134 regarding the composition of the Advisory Council.
Sand Canyon #3	GWMP should include timelines for completing its phases.	AB 3030 and AB 134.	Timelines are not required by AB 3030 or AB 134.
Sand Canyon #4	GWMP is lacking in its review of land use plans and coordination with land use agencies.	Water Code §10753.8(l)	See response to SCOPE Comment 3 above.
Sand Canyon #5	Perennial yield estimates for the Santa Clara River are higher than that provided in a Richard Slade report. Agricultural runoff is no longer a factor; agricultural usage was not metered historically, and former recharge areas have been paved.	Section IV (Existing and Projected Water Supplies)	See response to SCOPE Comment 8 above.
Sand Canyon #6	Santa Clara River should not be defined in terms of percolating groundwater. GWMP should clarify relationship between river and Saugus formation.	Section III	The GWMP is not an appropriate document in which to define the legal classification of groundwater, whether in the Alluvium or the Saugus Formation; consequently, there is no expression in the GWMP to describe the legal classification of groundwater in the basin. The entire focus of the GWMP is management of groundwater toward long-term preservation of both the quantity and quality of the resource.
Sand Canyon #7	GWMP's assertions against existence of overdraft or other undesirable conditions are incorrect since water levels in wells have reached historic lows. In addition, riparian conditions on the Santa Clara River and tributaries show signs of water deprivation.	Section III (Areas of Concern and Identified Problems)	See response to Sand Canyon Comment 1. Further, intermittent fluctuations reaching the equivalent of historic low levels is not overdraft. Primary Elements 1 and 3 are included to monitor groundwater levels throughout the basin, and to operate in an ongoing manner to avoid overdraft. Finally, the statement that riparian conditions show signs of water deprivation is non-specific as to location and is otherwise unsubstantiated. Primary Elements 1 and 2 are included in the Plan to quantify the existence and extent of such conditions, if they occur; Primary Element 3 is included to avoid overdraft- related conditions of the type noted.

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Sand Canyon #8	GWMP should include reports regarding water contamination from Robinson Ranch. City of Santa Clarita had stipulated that water quality adjacent to the golf course be monitored with results published in a report.	Primary Element 1	See response to UWCD Comment 1 regarding extent of detail regarding occurrence of groundwater as framework for understanding the objectives and elements of the GWMP. As regards this comment, there is no documented groundwater contamination from Robinson Ranch, including that golf course. Required reports on Robinson Ranch have not shown any contamination as alleged in this comment. Monitoring in accordance with Primary Element 1 is intended to detect any groundwater contamination of the nature alleged in this comment.
Friends of the Santa Clara River #1	Disappointed that GWMP's primary goal is "Development of Local Groundwater for Water Supply" because other objectives should include protection of groundwater resources.	AB 3030 and AB 134. Section II of GWMP	See response to SCOPE Comment 7 above regarding lack of priority for all management objectives, and lack of "primary" status for "Development of Local Groundwater for Water Supply".
Friends #2	GWMP should emphasize that paving of streams reduces recharge and should be avoided. Buffer zones around streams should be discussed.	This is not explicitly required by AB 3030 but relates to Primary Elements 1, 4 and 5 and Secondary Element 2	See response to SCOPE Comments 4, 5 and 6. Further, given the importance of in-channel recharge to the yield of the Alluvium, a priority in implementation of the Plan can logically be expected to be avoidance of paving stream channels.
Friends #3	Advisory Board should include representatives from environmental groups and county agencies.	Water Code Appendix § 103-15.1(c)(2)	CLWA complied with the requirements of AB 134 regarding the composition of the Advisory Council.
Santa Clarita Sierra Club Group #4	GWMP should include timelines for completion of components.	AB 3030 and AB 134.	Timelines are not required by AB 3030 or AB 134.

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Sierra Club #2	GWMP does not account for loss of groundwater from perchlorate contamination. "The numbers do not adequately represent the real water supply."	Primary Element 8; Water Code §10753.8(j)	See response to SCOPE Comment 10 regarding the inactivation of wells impacted by perchlorate contamination. The inactivation of certain wells impacts pumping capacity until the wells can be reactivated, with treatment if necessary, or replaced. However, perchlorate contamination does not reduce the available yield of the aquifer system, hence the numbers included in the GWMP accurately reflect the current state of water supply.
Sierra Club #3	Loss of groundwater due to development and pavement is not considered. GWMP must address coordination of land use with water necessities.	This is not explicitly required by AB 3030 but relates to Primary Elements 3, 4 and 5 and Secondary Element 2.	See responses to SCOPE Comments 4 and 6. Further, there has been no "loss" of groundwater due to development or pavement; groundwater conditions remain as generally described in Section III, with nearly constant water levels to the west and repetitive fluctuations to the east (see response to Sand Canyon Comment 1).
Sierra Club #4	Drought planning is inadequate as it fails to take account of loss of primary water sources and reclaimed water.	Primary Element 3, 4, 5 and 7	Drought planning is embedded in the GWMP in that the Plan is intended to result in groundwater management that ensures adequacy of groundwater supplies through both wet and dry (drought) hydrologic cycles. While "drought planning", per se, relates more specifically to overall water supply planning, of which groundwater is only one component, this Plan is intended to manage groundwater in such a way that it will be a reliable component of overall water supply through dry periods without being overdrafted on a long-term basis, e.g. through wet/normal periods that follow dry periods. Primary Elements 3, 4, 5 and 7 in the Plan relate to drought planning as well as parts of groundwater management through long-term fluctuations in hydrologic conditions.
Sierra Club #5	GWMP does not adequately discuss maintaining river and tributary habitats. Sierra Club supports a citizen monitoring program for water quality.	This is not explicitly required by AB 3030 but does relate to Secondary Element 7.	See response to SCOPE Comment 5 and Friends Comment 7.

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Sierra Club #6	CLWA should involve the public and other government and private entities in its water supply planning.	Water Code Appendix § 103-15.2(e)(2)	CLWA complied with the requirements of AB 134 regarding the composition of the Advisory Council.
Ed & Joan Dunn #1	Concern because CLWA did not hold more public meetings before release of draft. Concern whether CLWA has regularly met with Advisory Board.	Water Code § 10753 et seq.	CLWA has complied with all requirements thus far regarding public meetings and gone beyond that legally required.
Dunn #2	Doubt regarding replenishment of water in the Alluvial Aquifer.	Primary Elements 3, 4 and 5	Fundamentally, as discussed in the Plan, the long-term objectives for the basin include utilizing groundwater for water supply while not overdrafting the basin. As also discussed in the Plan, historically, in the western part of the basin there has been sufficient water for recharge to maintain an essentially full basin throughout both wet and dry hydrologic periods. Part of the reference to "sustain recharge" relates to that historical condition. Whether or not additional artificial recharge will be implemented in other parts of the basin, and what water sources might be used for such recharge, are to be addressed via implementation of the Plan, particularly Primary Elements 3, 4 and 5.
Dunn #3	Doubt over Richard Slade's assertion as to Alluvial Aquifer capacity.	This challenges evidence which the GWMP cites.	The analysis and determination of the storage capacity of the Alluvium has been exhaustively described in Slade's reports. The comment conveys no specific aspect of its "question"; the commentors are referred to Slade's reports, which address the storage calculations in proper technical detail.
Dunn #4	GWMP should state that SWP water was interrupted for 6 months in 1991. Newspaper clipping is provided for this point.	Primary Elements 3, 4 and 5	Primary Elements 3, 4 and 5 are included in the GWMP to ensure the maximum reliability of local groundwater in order to endure any future drought-related impacts on SWP deliveries, such as occurred in 1991.

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Dunn #5	Statement in GWMP that no wells exceeded DHS action level for perchlorate is false. Newspaper clippings provided	Section III (Groundwater Quality)	The Plan has been revised to reflect that, while there remains no primary or secondary drinking water standard for perchlorate, and although only some of the detected concentrations of perchlorate in the Saugus wells exceeded the Action Level established by the State Department of Health Services at that time (18 ug/l), all those wells were inactivated by their respective owners after detection of perchlorate; those wells remain out of municipal water supply service since then
Dunn #6	Statement that perchlorate contamination has not reduced groundwater capacity is misleading	Primary Element 8	See response to SCOPE Comment 10 and Sierra Club Comment 2
Dunn #7	The Urban Water Management Plan should not be referred to because it is under legal attack.	While it has been challenged, the UWMP is still a valid document	While it has been challenged, the UWMP is still a valid document and represents the current plan for urban water supply through its 20 year planning horizon. The Kern County Superior Court in February 2003 ruled completely in favor of the water suppliers in their defense of the UWMP litigation. The remaining petitioners have appealed
Dunn #8	The Saugus Formation does NOT underlie the entire CLWA service area	Section I (Santa Clara River Valley Groundwater Basin)	The text of the Plan has been revised to reflect that the Saugus Formation underlies much of the CLWA service area
Dunn #9	GWMP should state CLWA's inability to transport additional SWP to Santa Clarita Valley	Section IV (Existing and Projected Water Supplies)	CLWA does not have an inability to transport additional SWP water to the Santa Clarita Valley. Fundamentally, the comment is erroneous since the State conveys SWP water to CLWA's diversion points from Castaic Lake; from there CLWA has sufficient treatment and conveyance capacity for its current water demands, and is in the process of designing additional treatment plant capacity to treat and distribute additional water to accommodate projected increased demand

[illegible]

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Dunn #10	CLWA's recycled water program is for private business only, not public agencies.	Primary Element 7	The recycled water program has no restrictions against use by public agencies. As described in Primary Element 7, the integration of recycled water to meet some non-potable demand is expected to decrease overall demand for potable water by up to 17,000 afy. As public agencies develop capabilities to utilize recycled water for non-potable uses, they are expected to reduce potable water demands by integrating recycled water into their overall water delivery systems. Basically, recycled water service to a specific user or area frees up potable water supplies for other users or areas, thus enhancing the reliability of the overall water supply of the Valley.
Dunn #11	Groundwater production from both the Alluvium and Saugus Formation is overstated	Section IV (Existing and Projected Water Supplies)	The comment is unsubstantiated and includes no support in the form of records or other data to validate it. The historical use of groundwater reported in the Plan is based on a combination of metered pumping and indirect estimation of pumping based on metered power consumption and pump performance testing. There is no basis for claiming that reported groundwater production is "overstated".
Dunn #12	CLWA should develop an emergency plan.	Primary Elements 3, 4 and 5	Development of an emergency plan, presumably an emergency water supply plan, is beyond the scope of a GWMP. However, Primary Elements 3, 4 and 5 are intended to further develop both a regular and a dry year/emergency component of water supply from local groundwater.
Dunn #13	Chart depicting SWP water received in 1991 is erroneous. Newspaper clipping provided.	Figure 4-1	The final 1991 M&I allocation was 30% (October 1991). CLWA's M&I entitlement at that time was 41,500 af. The total amount made available to CLWA by DWR was 13,050 af. Since by October, CLWA and the retail purveyors had already instituted emergency operations, the entire amount was not used.

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Dunn #14	Claim that CLWA meetings with retail water purveyors, the City, and NCWD have not occurred.	Primary Element 9	The Commentors' lack of knowledge of such meetings does not mean they have not occurred. Appropriate documentation of such meetings, including presentation materials, discussion topics, and resultant work assignments, are maintained by meeting participants.
Dunn #15	Secret meetings and secret reports related to Primary Element 10 should not be included as part of the GWMP.	Primary Element 10	The preparation of the annual Water Reports does not indicate that any secret meetings have taken place. Previous Water Reports have been prepared, and future Water Reports are envisioned to be prepared with few, if any, meetings of any type; both public and private meetings have been convened to present and discuss the findings of the various Water Reports, and such meetings are intended to occur in the future for the same purpose.
Dunn #16	CLWA should provide an accounting of water conserved.	N/A	Providing an accounting of water conserved is beyond the scope of the GWMP. More water sales are occurring through time due to increasing demand in the Valley. Water conservation measures result in water savings even though demand is increasing.
Diane Trautman (City Planning Commissioner) #1	What percentage of water demand will be drawn from local groundwater?	Primary Element 5	In terms of groundwater management planning, projected urban water demand (the 106,000 afy projected urban demand in 2020) does not represent total valley-wide demand; total projected demand is 113,100 afy, including both urban and agricultural. In that light, on an average basis, local groundwater is expected to be utilized to meet about 40 percent of total water demand.

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Trautman #2	Will pumping of the Alluvial Aquifer reduce recharge of the Saugus Formation and reduce water that can be produced from the Saugus Formation during dry periods?	Primary Elements 3, 4 and 5	No. Since the Saugus Formation is recharged over a much larger area, beyond the spatial extent of the Alluvium, there is a limited relationship between Alluvial pumping and recharge to the Saugus Formation. The fundamental tenet of the GWMP is to utilize groundwater for water supply within its sustainable yield (see the Management Objectives, or Goals, for the Basin, GWMP Section II; see also the various GWMP Elements intended to achieve those objectives, GWMP Section V). In that light, it is expected and intended to operate in such a way that recharge to the Saugus Formation will not be "reduced" by pumping from the Alluvial Aquifer and that groundwater will be available in varying amounts, as needed depending on weather year-types, within the sustainable yields of the respective aquifers (i.e. without overdrafting them).
Trautman #3	Does CLWA have sufficient data regarding the Alluvial Aquifer and Saugus Formation, if not, how will it obtain such data?	Section III and Primary Element 1.	The reference to "useful amount of groundwater quality data" in the GWMP includes both Alluvial and Saugus data. However, due to the historically greater development and use of groundwater from the Alluvium (number and distribution of wells, volume of pumping), and due to the historically smaller development and use of the Saugus Formation (fewer wells, smaller geographical distribution of wells, smaller pumpage), there is comparatively limited ability to examine relationships among pumping, recharge, and quality in the Saugus Formation. CLWA and the other purveyors intend to expand the overall knowledge of the Saugus Formation as that resource is further explored and developed (number of wells, additional sampling as new wells are added, etc.). All that data will be included in ongoing implementation of GWMP Primary Element 1, Monitoring of Groundwater Levels, Quality and Production
Trautman #4	The 2002 Water Report indicates that "there are limited Saugus (Formation) water level data." Does CLWA plan to collect more comprehensive data on the Saugus Formation?	Section III and Primary Element 1	The "limited nature of Saugus water level data" is a result of the same smaller extent of historical Saugus development described in the preceding answer. Acquisition of additional data on the Saugus Formation is planned as also described in the preceding answer.

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Trautman #5	Is CLWA sharing detailed information with the City of Santa Clarita regarding contamination risks in relation to existing closed wells?	Primary Element 9	All publicly available information regarding the investigation of perchlorate contamination, its extent, its impact on water supply, and plans for cleanup, control of migration, etc. is available to the City. Representatives of CLWA and the purveyors meet routinely with City representatives to review the status of perchlorate cleanup and remediation activities. CLWA and the impacted water purveyors will continue to pursue control and cleanup of perchlorate contamination in order to restore impacted groundwater pumping capacity and to ensure the long term quantity and quality of groundwater in accordance with the GWMP. As a practical matter, there are no surface contamination risks relating to perchlorate that would affect land use development adjacent to the impacted wells.
Trautman #6	Where is the Stadium Well located?	Section IV (Groundwater Quality)	The Stadium Well is located on the south side of the Santa Clara River, approximately two miles upstream (east) of its confluence with the South Fork tributary, or about 4,000 feet east of the Bouquet Canyon Road crossing of the Santa Clara River.
Trautman #7	Why isn't conservation a primary element (instead of secondary) since it may reduce water demand by 10%?	Secondary Element 1	The assignment of "primary" or "secondary" status to any GWMP element is discretionary and certainly not absolute. Secondary status is not intended to indicate that any element of the GWMP will not be implemented; all elements are intended to be implemented. Final status of all GWMP elements will be reviewed by the Advisory Council and the CLWA Board.

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Trautman #8	How is CLWA delivering recycled water?	Primary Element 7	Recycled water is being delivered to the TPC golf course, the first customer of the system, via the dedicated, recycled water distribution system, which is also capable of delivering water to other non-potable water users, and which will be expanded in accordance with the Draft Recycled Water Master Plan. The costs and time frame for expanding recycled water distribution and use are included in the Draft Recycled Water Master Plan which is complementary to, but beyond the scope of the Groundwater Management Plan. The intent is to develop 17,000 afy of recycled water use by 2020. The capital cost of the complete system is estimated to be $68 million, and will be funded through CLWA's connection fee program.
Trautman #9	How is recycled water reprocessed?	Primary Element 7	Recycled water is not "reprocessed" at points of use such as the TPC golf course. In general, recycled water is highly treated (tertiary treated) waste water. In the case of the Santa Clarita Valley, treatment already occurs at the Valencia Reclamation Plant operated by the Sanitation Districts of Los Angeles County. The treated water, ready for non-potable use, is distributed from the plant site in a dedicated transmission pipeline system to end users such as the TPC. Pesticide and fertilizer uses, as part of cultural practices at end-user locations such as golf courses, are discretionary actions of the respective end users of recycled water.
Trautman #10	What is the average per capita water usage?	N/A	Most water agencies no longer use "per capita" water use as a standard because it is not an accurate representation of actual per person water use, mainly due to the effects of landscape and commercial/industrial water use. (It is also expressed in "gallons per day," rather than "acre-feet per year," since it refers to individual water usage.) In general for the South Coast hydrologic region of California, water use is approximately 200 gallons per person per day (DWR Bulletin 160-98). Per capita use for the Santa Clarita Valley is slightly higher due to landscape irrigation demands caused by local climatic conditions.

PARTY	COMMENT	APPLICABLE GWMP SECTION/ COMPLIANCE[1]	RESPONSE
Trautwein #21	The Semitropic Water Bank/Transfer is not mentioned in discussion of the Supplemental (SWP) Surface Water on page 21. Is that because it is a relatively short-term water supply? Are any of the other water transfers -- Kern Water Bank, Kern Delta Water, North Las Posas Water Bank -- as listed on GWMP p. 2-16, of limited duration? And if the Semitropic Water Bank Transfer is short term, how can it be included in the 305,000-308,000 afy need projected for the next 20 years? When will take its place?	Section IV (Existing and Projected Supplies)	The SWP is referred to as "supplemental" water because that is the original purpose of the SWP: to serve as a supply that would "supplement" local supplies (whether groundwater or local surface water or both). The specific amounts referred to in the GWMP are from the contractual terms between CLWA and the California Department of Water Resources. The water banked in the Semitropic Water Storage Program during 2002 is a short-term, dry period supply. The program has a term of ten years (i.e., the water must be returned to CLWA for use in its service area within that time period). Thus it is not included as a supply for long-term needs. However, the other programs listed in the GWMP (most of which, by the way, are not water "transfers," but are instead groundwater banking programs) are long-term sources of supply. CLWA is in the process of designing and implementing a Long-Term Reliability Plan to begin bringing such long-term programs on line as a means to store water available in wet years, for use in later dry years. CEQA analysis, with its accompanying public comment opportunities, will be part of the long term reliability program approval process.
Trautwein #12	What specific efforts will be made to manage salinity?	Primary Element 6	Primary Element 6 – Long Term Salinity Management is included in the GWMP for the reasons presented in the text discussion of that element. The element recognizes the need to plan for salinity management but also recognizes that, to the present, there has been no extraordinary trend of salinity increase. Hence, there are no specific efforts currently in place to "manage" salinity. It is envisioned that specific efforts will be developed over time in response to implementation of the GWMP and, in particular, its Primary Element 6. CLWA is participating in efforts by the Sanitation Districts of Los Angeles County to address the Los Angeles Regional Water Quality Control Board's proposed TMDL standard for chloride in the Santa Clara River. This effort is separate from and beyond the scope of the Groundwater Management Plan.

Re: Response on Draft Groundwater Management Plan, Santa Clara River Valley Groundwater Basin, East Sub-basin

Thank you for giving us the opportunity to review and comment on your *Draft Groundwater Management Plan, Santa Clara River Valley Groundwater Basin, East Sub-basin*. United Water considers this plan as one piece of a broader effort at groundwater management that is being accomplished as part of the Memorandum of Understanding between United Water and water purveyors in the Santa Clarita area. We offer some specific comments and suggestions for your consideration.

Comments include:

Figure 3-2. The vertical and horizontal scales associated with the hydrographs are very difficult to read. The T4N R17W, Section 22 well, in the western arm of the Alluvial Aquifer does not show data from approximately 1983 through 1991. In previous reports and analyses, the NLF #C5 well was used for this area. This well depicted variable groundwater levels for the period from the mid-1980s to the early 1990s. Because this is the discharge area of the Alluvial Aquifer to the Santa Clara River, we need to understand the response of the system to the onset of agricultural pumping in this area in the mid-1980s. The T4N R17W, Section 22 well does not possess the data needed to show that response.

Page 15. The comment near the top of the page that "*over the last 35 years, groundwater quality in the Saugus has remained generally constant*" would be more supportable if it was accompanied by a groundwater quality map similar to Figure 5-5, with a few groundwater quality time-series specific to the Saugus Formation.

Figure 5-3. The average daily mean streamflow data appears to be shifted one year on the histogram graph. As an example to show the error, the histograms suggest that there were high flow years in 1968 and 1997. The high flow years were actually 1969 and 1998.

UNITED WATER CONSERVATION DISTRICT

Page 27. Local Groundwater. The planned production of 30,000 to 40,000 acre-feet per year from the Alluvial Aquifer and 7,500 to 15,000 acre-feet per year from the Saugus Formation, along with 11,000 to 30,000 acre-feet per year from the Saugus in dry years has yet to be implemented. The current development of a regional transient groundwater flow model for the East Sub-basin is for the expressed purpose of evaluating the potential impacts to the basin and surface water outflow into Ventura County, of this increased pumping. Irrespective of the modeling results, only real groundwater and surface water data can verify the influence of significantly increased pumping within the sub-basin; and

Page 29. Primary Element 2 – Monitoring and Management of Surface Water Flows and Quality. While imported SWP water no doubt contributes to the observed increased flow in the Santa Clara River at the Ventura County line, there exist additional explanations for a portion of the increased flow. Other considerations include:

1. Influence of the hydrologic cycle. The cumulative departure for precipitation was declining during the 1950s and first half of the 1960s. The cumulative departure improved significantly during the period of 1978 through 1983; and
2. The amount of Alluvial Aquifer pumping may influence flow at the Ventura County line. During the latter half of the 1960's and through the 1970s, groundwater pumping of the Alluvial Aquifer declined by 50%. Pumping during the 1980s was 50% lower than during the 1950s and early 1960s.

In this particular case, it would be very difficult to differentiate between the influence on streamflow from changes to groundwater pumping and the hydrologic changes.

If you have any questions about United Water's comments, please contact Steve Bachman at (805) 525-4431.

Sincerely,

Dana L. Wisehart

Re: Comments on Ground Water Management Plan

Dear Sirs

Thank-you for the opportunity to comment on your plan. We are pleased that your agency has begun a ground water management plan in response to the community's concerns over the excessive use of ground water. This extensive pumping and lack of protection of re-charge areas has resulted in almost complete elimination of surface flows and summer ponding necessary to wildlife as well as causing water level drops in wells that have resulted in water quality and availability problems for small users

General Areas of Concern

We regret that environmental organizations, small well owners, the City of Santa Clarita, the County of Los Angeles (watershed and flood control divisions), Regional Water Quality Control and other members of the community interested in water issues in our valley were not included on your advisory board. We believe that inclusion of these groups early on would have helped resolved some of the issues with your plan at an earlier stage. Including only the water companies, Newhall Land and Robinson Ranch effectively excluded many of the groups and individuals that have voiced strong concerns over your present actions. The water agencies have consistently excluded these groups from all water planning, including water supply reports and the Urban Water Management Plan process. We strongly suggest that a more inclusive committee be formed to include representatives of the environmental community and rural well owners who are now being affected by overdraft of the Santa Clara River

We also note that there are no timelines for completion of any of the components of the plan. Without such timelines, it would seem that there is little real intention or commitment to follow through on the various parts of the plan

The Land Use/Wellhead Protection Component of the Groundwater Management Plan

Perhaps the most significant out come of a ground water management plan in the Santa Clarita Valley would be implementation of the portion of Section 10753 which requires review of land use plans and coordination with land use agencies. Your plan assigns this area to

"Secondary element 2", an indication that you do not intend to pay much attention to this important component.

The coordination of land use and water planning has been sadly lacking in the Santa Clarita Valley. A simple wellhead protection plan would help decision makers understand the potentially polluting impacts of certain land uses such as gas stations, auto repair shops, etc and how they could negatively affect our water supply. Instead, these uses are routinely permitted next to water supply wells.

Paving over of prime re-charge areas is allowed without a word of protest from the water agencies, even though such loss of recharge capacity will severely affect water availability. Recreational uses should be encouraged in recharge areas that will accommodate and perhaps even enhance water re-charge and thus increase water availability.

Newhall County Water District began a well head protection program and educational presentations with its ground water management plan in the mid 90's, but efforts to both educate the planners and protect re-charge and water supply wells have been stalled by the strong developer involvement with water agency decisions. This involvement has precluded advocacy of long term decisions that would protect water availability and water quality in favor of short term profits for development companies.

The ground water management plan should stress the importance of avoiding the concreting of tributaries when approving new land uses and require adequate set back from natural water courses to allow these blue line streams to remain in a natural state. This will enhance water re-charge (and thus, ensure water availability). It will also aid water quality because riparian vegetation absorbs many pollutants before they can enter the ground water system.

It is an indication of the myopic view of the water agencies that this plan states its number one goal to be "Development of Local Groundwater for Water Supply". There are many other uses of ground water and surface water which are important to the community. These include recreational and aesthetic values, biological value and the quality of the water supply. More pumping will result in diminution of all these other aspects of our ground water resource and ignore the strong protests and demands for their protection which are already being heard from many voices in the community.

<u>Monitoring of Ground Water and Surface to Establish Safe Yield</u>

Agricultural Water Usage is Overestimated

In its presentation, Luhdorff and Scalmanini revise the previous perennial yield estimate of the Santa Clara River by Richard Slade (perennial yield 32,600 AF, Hydrology of the Alluvial Sediments of the Santa Clara River, 1988, page 109) to approximately 47,000 AF. This revision is based in part on an average agricultural usage from the 1940s to the 1960s. We believe that these calculations are incorrect for three reasons.

1. No inclusion of recharge from agricultural run-off was included in the usage calculations as was included in previous reports. Agricultural run-off was a substantial source of re-charge to the river that no longer exists, therefore not as much water is available for extraction.

2. Agricultural withdrawal was not metered, so water usage is merely an estimate based on crops and weather. It appears that estimates of withdrawals may have been over-stated.
3. Agricultural lands provided a source of recharge during wet years. Urbanization has paved over most of this area, so recharge is no longer occurring. This will reduce that amount of recharge to the river alluvium and thus reduce the amount available for extraction. (Slade, 1988, Hydrological Investigation of the Perennial Yield of the Alluvial Aquifer, page 88)

These evaluation errors have caused the water companies to believe that they can withdraw a higher amount of water than can actually occur without causing impacts to public trust matters and small well users.

Monitoring and Managing Surface Water Flows

Visual Historical Evidence has been ignored

There are numerous records and observations by long-time residents indicating that surface flow usually occurred year round. Ponding that harbored fish and amphibians (many of which are listed as threatened or endangered) in areas that did not support year round flow has also been attested to by local residents. The disappearance of year-round flows and ponding is an indication of overdraft of the alluvial system. The impacts to riparian life and water quality are substantial. A goal of returning or replacing these summer surface waters should be incorporated in your plan. Such replacement may help to avoid potential future litigation brought to enforce the Endangered Species Act.

Water Quality Monitoring

Water Pollution

We appreciate that the water agencies have finally admitted that 5 municipal wells are closed and that there is a concern that the pollution plume is moving in a westerly direction (Plan at page 32). It is very regrettable that these facts were not disclosed to decision makers over the past several years and, further, were even denied by representatives of the water agencies.

However, we believe it is imperative that this plan additionally include a disclosure of the current reduction in production capability due to pollution of the Saugus and alluvial aquifer by ammonium perchlorate. Continued pumping may extend the pollution plume and increase clean-up costs. It is important that the extent of the problem be honestly outlined for the public so that alternative remedies may be devised and discussed. Failure to disclose the extent of the pollution problem and its real impact may lead to serious water quality problems if the Saugus aquifer is relied upon for drought supply.

Conclusion

We submit the following recommendations:

1. We encourage CLWA to re-form its advisory committee to be inclusive of the community and other local agencies.

2. We suggest that the goals of the plan be re-ordered to place land use issues in a position of significance, and include recommendations from other agencies, organizations and individuals that might enhance water availability and water quality
3. A time line must be established, financial commitment discussed, and responsibility assigned so that the water management goals will actually be attained.

Sincerely

Pat Saletore

RE: Groundwater Management Plan ("AB 3030 Plan")

Gentlemen:

This letter is in response to your letter of June 16, 2003 which solicited comments about the above plan to ensure that the general public has had the opportunity to provide input on this local effort to manage our community's groundwater resources.

We are pleased to respond to your request for public participation. As well using residents of the Sand Canyon area who are affected by ground water use and plans for future use of it, we feel that our interests are very much at stake in determining how our river and ground water is to be used.

Our first and foremost concerns are that both river and ground water is being extensively pumped and that recharge areas are not being adequately protected. Surface flows and summer ponds have virtually vanished from our vicinity. In 1997, the water level in four wells adjacent to Sand Canyon Creek stood at twelve feet. As of last month, those same wells' water level now stands at ninety-three feet.

Other general concerns include the lack of representation on your advisory board by rural well owners. While water companies and the Robinson Ranch Golf Course have their own interests in how our community's water resources are used, many small well users have an equally valid interest in seeing that our area's water resources are managed in an equitable fashion that ensures no entity's use will result in the deprivation of others.

Also, none of we Sand Canyon area small well users have been consulted during the creation of water supply reports or the Urban Water Management Plan, despite the fact we are being affected by an increasingly serious overdraft of the Santa Clara River. Including members of our group in a groundwater management committee will bring important stakeholders to the planning process. We have important data to present.

It is disappointing to note that the ground water management plan specifies no timelines or dates for executing and completing its phases. We question whether there is sincere intent to carry out the plan given the lack of work plan.

On a broader scale, we are deeply concerned about the plan's land use and wellhead protection sections. Section 10753 calls for a review of land us plans and coordination with land use agencies, as stipulated in secondary element 2 of the plan. A critically important aspect of effective ground water management, such coordination has not taken place to any meaningful extent in the Santa Clarita Valley, and more specifically, in the Sand Canyon area. We have noted with dismay that vital recharge areas have been built upon and paved over with no comment from any water agencies, despite an obvious impact on water availability for all water users, particularly small well holders.

While intelligently planned development is meant to result in well designed, livable communities where all inhabitants are assured of fair access to resources, we note that ongoing strong developer involvement with water agency decisions has led to the potential compromise of water availability and quality in exchange for near term profits for developers and increased tax revenues for local governments.

In the draft plan's sections that deal with ground water monitoring to establish a safe yield, we believe that estimates of agricultural water consumption are not accurate. In Richard Slade's 1988 perennial yield estimate of the Santa Clara River, he stated on page 109 that it was approximately 32,000 acre-feet. Yet Luhdroff and Scalmanini raise this estimate to 40,000 acre feet. They base their calculations on data measured for agricultural operations between the 1940's and 1960's.

Since our membership includes individuals who have farmed a large parcel in the Sand Canyon area from 1951, we feel qualified to comment on the above figures.

First, agricultural usage during the reference years was never metered. Usage during this period is estimated based on available crop reports (when they were recorded) and available weather data. A reading of withdrawal estimates raises a suspicion that they are overstated.

Second, the upward revision of Slade does not include agricultural runoff. Since agriculture in our area has virtually disappeared, it is no longer a contributing factor to aquifer recharge. Yet earlier estimates included agricultural runoff, a significant source of recharge.

Third, land in our area that previously was planted in both irrigated and dry land crops has now been paved over. During rainy years, farm fields were an important component of recharge, since rain soaked into them. Slade specifically mentions this reduction of extractable water on page 88 of his 1988 report.

Flawed calculations like these have caused water companies and other institutional users to think that they can extract more water than they can and should without adversely affecting small well users.

Primary element number two gives the appearance of an attempt to establish a commingled inter relationship between the Saugus Formation and the Santa Clara River. With a clearly defined bed and banks, the Santa Clara River has historically behaved as a river, and despite severe depletion from over pumping, still exhibits the dynamics of a river during episodes of precipitation. With our members holding rights of diversion from the State Water Resources Board, we strongly feel that any attempt to define the river in terms of percolating groundwater defies logic and the laws of physics.

Also, in the "Existing and Projected Water Supplies" section, the draft report states that "...it is currently expected that ongoing utilization of local groundwater will continue to be in amounts that have historically been pumped, 30,000 to 40,000 afy from the Alluvium..."

As stated above, Slade's 1988 report clearly and unequivocally sets the upper pumping limit of the Santa Clara flow at 32,000 afy. By relying on generous overstatements and exaggerated potentials, a plan will go forward that will have serious negative impacts for small well users in the Sand Canyon area.

In primary element three, Determination of Basin Yield and Avoidance of Overdraft, we are concerned with the second paragraph's first sentence that states "...there has not been any widespread, steady degradation of groundwater conditions that might be indicative of overdraft..."

Again in Primary Element 4, the second sentence asserts..."Both ranges of numbers are consistent with recent historical pumping that has not resulted in any indication of overdraft or other undesirable conditions." And in Primary Element 5, the third sentence further posits that ..."Groundwater pumping has remained within a range that has not caused any evidence of overdraft, or associated undesirable impacts..."

It is the direct and incontrovertible evidence of water levels in our own wells that presents us with a clear contradiction to this assertion. Based on members' records that cover a fifty-year span, the current water levels in our wells have reached an unprecedented low. We are left with inescapable evidence that large users pumping from the Santa Clara River have contributed to a cone of depression that is negatively affecting our small wells.

In addition, riparian conditions along the tributaries and main channel of the Santa Clara River reflect highly stressed, water deprived environments. In areas away from river feeder creeks, some heritage California Coastal Oaks (Quericus Agrifolia) have begun showing signs of water deprivation.

In a related matter, the proposed plan calls for identification of potential sources of contamination to assure water quality. When Robinson Ranch Golf Course was granted permission to open and operate, the city stipulated that water quality adjacent to and on the golf course be monitored and that regular reports about it be published. These reports have not been included in the draft plan, despite the fact that Robinson Ranch is a participant on the advisory committee for this draft plan. Pesticide, insecticide, fertilizer, and other volatile organic compounds are all possible runoff and plume contaminants that may be leaching from the golf course.

As members of your advisory committee, we would be glad to share with others the data from five decades of small well usage. We believe that recent developments, specifically in our area, have seriously lowered both the alluvial water levels to historic levels.

While modeling, projection, and prediction can yield abstract theories, we small well users must live with the consequences of miscalculation, however unintentional or inadvertent.

Small well holders are franchised, integral, entitled members of the water using community, and as such, must be included in the planning process associated with any groundwater management plan that is to be implemented in the Santa Clarita Valley.

Primary element nine specifies a MOU (Memorandum of Understanding) executed between the United Water Conservation District in Ventura County as an example of…"a local agency relationship that has produced the beginnings of local groundwater management, now embodied in this comprehensive (sic) plan…" While we laud all attempts to widen the base of data and participation in the planning process for water resources, we are disappointed that as stakeholders in the Eastern Sub basin of the Santa Clara River Valley, our interests are not being represented on the advisory committee that has been created to direct the groundwater management plan.

We ask to be included in the planning committee that is helping to shape the future of water use in our community.

Respectfully,

The Sand Canyon Area Well Owners Association

Re: Groundwater Management Plan

Dear Sirs,

Friends of the Santa Clara River submits the following comments on the June 2003 Draft Groundwater Management Plan (Plan).

We are disappointed and dismayed that the Plan sets as its primary goal the "Development of Local Groundwater for Water Supply". While providing adequate water supplies is an important objective, it would seem to us that the primary goal should be the long-term protection of local groundwater resources, including groundwater quality. Groundwater resources provide many benefits to the community, including those related to the biological and environmental health of the river corridor. Long-term protection, if implemented, should curtail the over-pumping of local aquifers which is currently occurring.

We are also concerned that water agencies, in general, have failed to weigh-in on the paving over of recharge areas in the Santa Clarita Valley. Loss of recharge could have very substantial impacts on future water availability. The Plan should emphasize that concreting of ephemeral tributary streams reduces recharge, and thus should be avoided. Adequate setbacks, or buffer zones, around major streams should be stressed - an item that is rarely adequately addressed in development projects.

The Plan advisory board is too narrowly constituted. The Regional Water Quality Control Board should be represented, as should environmental groups and county agencies working on watershed protection.

Thank you for the opportunity to comment.

Sincerely,

Ron Bottorff

RE: Ground Water Management Plan Comments

Dear Directors,

We appreciate the chance to comment on the ground water management plan. This plan has been a long time in the making. We hope that your response to concerned public input will make it a viable document. A few comments follow.

1. Based on the (too) long history of this plan, it is essential to include deadlines (with penalties for failure) for completion of the various components of the plan. Otherwise our water will just slip away.

2. There is no accounting for loss of groundwater from pollution such as perchlorates. As soon as the magnitude of the problem has been adequately determined, a realistic plan can then be implemented. As it stands right now, the numbers do not adequately represent the real water supply.

3. Loss of groundwater due to loss of percolation due to extensive development, which paves over permeable soil, is not considered. It is a continuous and cumulative impact on the water supply. More generally, the water plan must address coordination of land use with water necessities such as the preservation of water percolation basins and similar amenities.

4. Drought planning is inadequate in the plan. For example, if a water treatment plant is built, then a certain number of acre ft of water can be reclaimed. Current planning would say that this is real water, which can be counted on. In a drought, not only do you lose primary water sources, but also the corresponding amount of reclaimed water, a double hit which must be accounted for in any realistic water plan.

5. The Sierra Club strongly supports an active river-monitoring program so that potential and existing water quality issues can be addressed in a timely manner. This must be an integral part of the plan. In lieu of the water agency producing reliable data, a citizen-monitoring program will have to be undertaken to assure the quality of our water.

6. The plan does not adequately discuss maintaining river and tributary habitats such as the biological unhealthy zones created from the Rio Vista Plant's outflow into the Santa Clara River. While there are green plants growing in the area, UCLA researchers have shown that it is barren of many insects, which would normally be present in such an environment. This engenders a ripple effect in the biota.

7. Just as the City of Santa Clarita involves the public and other government and private agencies in its long range planning, CLWA should do the same with its water planning. People in the Santa Clarita Valley are just beginning to realize the importance and the fragility of their water supply. The time to start REAL planning is now.

Thanks for your kind attention.

RE: Groundwater Management Plan (AB 3030)

Dear Sirs:

We are pleased to have the opportunity to comment on your draft AB 3030 Plan. Enclosed please find copies of individual pages of this plan and associated comments for these pages.

We are disappointed that the writing of this plan appears to be following the same path of the UWMP. We are also displeased there has not been an attempt to hold more public meetings prior to this draft release. As required in AB 134, when has the agency met regularly with the advisory council to consult on this plan? What was the frequency of the meetings and how many were there?

We are quite interested in an AB 3030 Plan and would appreciated this draft be made into an honest and truthful document, allowing it to go ahead on a timely schedule without challenges and delays.

Respectfully submitted,

Ed and Joan Dunn

Enclosures: 3 Exhibits, 16 draft groundwater pages and 16 associated comment pages

Plan, page #8

Dunn, page 2

Top of page:
Basin objective "manage groundwater levels and discharge to the Santa Clara River, at the west end of the basin"?
Wording should include "the entire basin".

Bottom paragraph, last sentence.
The plan is replenishing the aquifer with WHAT sufficient water"

and effects, e.g. chronic water level decline, loss of groundwater storage, onset of land subsidence, groundwater quality degradation, a corresponding basin objective is to manage groundwater levels and associated groundwater discharge to the Santa Clara River at the west end of the basin, and thus not adversely impact surface and groundwater discharges to the downstream basin(s).

3. Preservation of groundwater quality for beneficial use in the basin, and for beneficial use of surface water and groundwater discharges from the basin. Included in this management goal will be the active characterization and solution of any groundwater contamination problems, through cooperation with responsible parties or through independent action if timely action by responsible parties is not forthcoming and the preceding management objectives are thereby impacted or constrained.

4. Preservation of interrelated surface water resources. Included in this management goal will be the maintenance of appropriate surface water flows and non-degradation of surface water quality as a result of managing groundwater conditions to meet the other management goals for the basin.

Quantitatively, the preceding goals translate into general preservation of groundwater levels and quality in the Alluvial aquifer system consistent with the last 30 years, including fluctuations through seasonal demands and local hydrologic variations (wet and dry periods). As discussed in more detail in the next chapter, the hydrogeologic setting in the area has resulted in smaller Alluvial groundwater level fluctuations toward the western half of the basin (generally west of Bouquet Canyon), and larger fluctuations to the east. However, largely due in part to the importation of supplemental surface water over the last 20 years, and the integrated or conjunctive use of that supplemental water with local groundwater, there has been no chronic decline in groundwater levels or storage. A continuation of such basin conditions, possibly complemented by management actions to decrease the historical water level fluctuations in the eastern part of the basin, will accomplish the second basin objective, continued avoidance of overdraft as has been the ongoing historical condition in the basin, while continuing to utilize local groundwater to meet part of projected water requirements, the latter being the first management objective for the basin. Corresponding management actions to sustain recharge and not overdraft groundwater storage will accomplish the third basin objective by replenishing the aquifer system with sufficient water to sustain what has been generally consistent quality of groundwater on a long-term basis.

Plan, page #10 Doc., page3

We question Slades 1986 and 2002 Report stating the alluvium has the capacity of 240,000 acre feet.

III. Groundwater Basin Conditions

Occurrence of Groundwater

Groundwater in the Santa Clara River Valley East groundwater subbasin occurs in two aquifer systems, the Alluvium associated with the Santa Clara River and its tributaries, and the Saugus Formation. There are also some scattered outcrops of Terrace deposits in the basin that likely have the capacity to contain limited amounts of groundwater; however, since these deposits are located in limited areas that are situated at elevations above the regional water table and are also of limited thickness, they are of no practical significance as aquifers and have consequently not been developed for water supply.

The Alluvial aquifer system, of Quaternary to Holocene (Recent) geologic age, consists primarily of stream channel and flood plain deposits of the Santa Clara River and its tributaries. The Alluvium is deepest along the center of the present river channel, with a maximum thickness of about 200 feet near the area known as Saugus. It thins toward the flanks of the adjoining hills and toward the eastern and western boundaries of the basin and, in the tributaries, becomes a mere veneer in their upper reaches. The spatial extent of the Alluvium throughout the basin is illustrated in Figure 3-1.

The Alluvium is the most permeable of the local aquifer units. Based on well yields and aquifer testing, transmissivity values in the range of 50,000 to 500,000 gallons per day per foot (gpd/ft) have been reported for the Alluvium, with the higher values where the Alluvium is thickest in the center of the valley and generally west of Bouquet Canyon (Slade 1986 & 2002). The amount of groundwater in storage can vary considerably because of the effects of recharge, discharge, and pumping from the aquifer. The maximum storage capacity of the Alluvium has been estimated to be about 240,000 acre-feet (af) (Slade, 1986 & 2002).

The Saugus Formation, of Pliocene to Pleistocene geologic age, has traditionally been divided into two stratigraphic units, the lowermost, geologically older Sunshine Ranch member, which is of mixed marine to terrestrial (non-marine) origin; and the overlying, or upper, portion of the Formation which is entirely terrestrial in origin. The Sunshine Ranch Member of the Saugus Formation has a maximum thickness of about 3,000 to 3,500 feet in the central part of the valley,

Plan, page #12 Dunn, page 4

Top, bottom of first paragraph

The plan states "the most significant period of Saugus pumpage was 1991 through 1994, when pumpage ranged from 10,600 afy to nearly 15,000 afy and averaged over 12,000 afy, during which time SWP water deliveries were reduced at the end of extended drought conditions".

It should be stated that the SWP water was INTERRUPTED for approximately 6 months. See Feb. 27,1991 Daily News newspaper article " Santa Clarita will turn to wells as state water supplies dry up". As stated in the article, the SWP water processing plant was shut down. Exhibit A.

"Officials say state's water delivery system inadequate". See Exhibit B

Since 1980, total pumpage from the Saugus Formation has ranged between about 3,850 afy and nearly 15,000 afy; average pumpage over that period has been about 6,900 afy. The great majority of pumpage from the Saugus is for municipal supply (nearly 6,400 afy, or 93 percent on average). For comparison, although historical Saugus pumping records prior to 1980 are limited, there appears to have been essentially no pumping from the Saugus prior to 1960 (on the order of about 100 af in most years, beginning in 1948), and some increased pumping for agricultural water supply beginning in about 1962 (about 900 af). The largest amount of agricultural pumping from the Saugus was during the mid-1960's, when annual Saugus pumpage was about 3,000 af. Agricultural pumping from the Saugus declined to near zero by the late 1970's, but has been generally in the 500 to 1,000 afy range since 1982. There was no Saugus pumpage for municipal supply in the early 1960's; limited data suggests that municipal pumping from the Saugus began in the 1970's, and reached nearly 5,000 afy by 1980-81. The most significant period of Saugus pumpage was 1991 through 1994, when pumpage ranged from 10,600 afy to nearly 15,000 afy and averaged over 12,000 afy, during which time SWP water deliveries were reduced at the end of extended drought conditions.

Groundwater Monitoring Network and Program

There is no formal groundwater monitoring network of wells for groundwater level measurements and/or groundwater quality sampling in the basin. Consequently, one component of this Plan is to formalize both a network of wells for groundwater monitoring and a program for water level measurements, water quality sampling, and other pertinent groundwater data collection (Primary Plan Element 1). Despite the lack of an existing formal groundwater monitoring network and program, however, there is a significant amount of historical groundwater data, some of which dates back into the 1940's, on which to base reasonable assessments of groundwater conditions in the basin. For example, groundwater level measurements have been made over varying periods of record in a total of 154 wells, mostly alluvial wells, throughout the basin. Similarly, groundwater quality data, consisting of varying numbers of constituents analyzed, are available from some wells, but a much smaller number than is the case for groundwater level data. These data, along with direct measurements or indirect estimates of pumpage, primarily from high capacity municipal and agricultural wells, allow for analysis of groundwater basin conditions, as discussed in this Plan, and also provide the bases on which a groundwater model can be developed (Primary Plan Element 5) and on which various management criteria such as operational yield, baseline groundwater quality, etc. can be determined (Primary Plan Elements 3, [illegible] etc.).

Plan. page #15 Draft. page 5

Middle paragraph.
"Exceedence of action level of perchlorate".
Newhall County Water District perchlorate level was 19 micro-grams per liter and Santa Clarita Water Co. was 24 or more micro-grams per liter.
The statement that none (no wells) exceeded 18 micro-grams per liter is false. See Exhibit C

higher quality (low TDS) water and dry periods have resulted in the notable declines in water levels described above, with a corresponding increase in TDS (and individual component constituents) in the deeper parts of the Alluvium.

Due to a much more limited number of wells and the limited spatial extent of groundwater development in the Saugus Formation, long-term Saugus groundwater quality data are not sufficiently extensive to permit any sort of basin-wide analysis or assessment of pumping-related impacts on quality. Based on the most complete historical record, over the last 35 years, however, groundwater quality in the Saugus has remained generally constant, and the Saugus Formation is, on a groundwater quality basis, a viable agricultural and municipal water supply.

The most notable groundwater quality issue in the basin centers around the detection and impact of perchlorate on several Saugus wells and one Alluvial well in the central part of the basin near the location of the former Whittaker Bermite facility, which is immediately southeast of the confluence of the main Santa Clara River and its South Fork tributary. In 1997, routine water quality sampling detected the presence of perchlorate in four municipal wells completed in the Saugus Formation (CLWA Santa Clarita Water Division Saugus Wells 1 and 2, Newhall County Water District Well 11, and Valencia Water Company Well 157). While there remains no primary or secondary drinking water standard for perchlorate, and although the detected concentrations of perchlorate in the Saugus wells did not exceed the Action Level established by the State Department of Health Services at that time (18 ug/l), all those wells were inactivated by their respective owners after detection of perchlorate; those wells remain out of municipal water supply service to date.

More recently, in late 2002, routine water quality sampling of Alluvial wells detected perchlorate in one of them (CLWA Santa Clarita Water Division Stadium Well) at a concentration which slightly exceeds the current Action Level (4 ug/l). This well has also been voluntarily inactivated, and thus remains removed from municipal water supply service.

This Plan, notably through Primary Plan Elements 1, 6 and 8, is intended to incorporate both short-term and long-term groundwater quality considerations in the management of the groundwater basin in order to formalize groundwater quality monitoring and assessment, to investigate and correct groundwater contamination problems, and to preserve or improve groundwater quality for ongoing water supply as well as for avoiding adverse water quality impacts on interconnected surface waters.

Plan, page 19 Dunn, page 6

Paragraph #2.
The statement of this paragraph is misleading. The correction should show "out of service wells significantly reduced groundwater capacity for existing groundwater supplies, so much so, that a substantial increase of state water use, has been instigated".

Areas of Concern and Identified Problems

A number of concerns have been expressed about groundwater conditions in the basin. While not all of the expressed concerns have been substantiated, they are listed and briefly discussed here, and they are addressed in the management objectives for the basin, intended to be achieved via implementation of the various primary and secondary elements in this Plan.

The most notable concern in the basin, at least at present, is the impact of perchlorate contamination on a number of municipal water supply wells, thus affecting the available pumping capacity from some municipal wells. While perchlorate impacts on a few wells do not preclude the ability to pump groundwater in accordance with existing water supply plans, activities to characterize the contamination, and ultimately to control it and treat it, have been initiated in order to return the impacted wells' pumping capacity to water supply service. Primary Element 8 is included in this Plan to formalize the addressing of groundwater contamination issues in the basin.

Concern has also been expressed that groundwater development in the basin will adversely impact the quantity and/or quality of surface flows leaving the basin via the Santa Clara River. Such concern extends to the potential impact on groundwater in the next downstream basin, the Piru Basin in Ventura County. While there are no established provisions regarding surface flows out of the Santa Clara River Valley East subbasin, Primary Element 3 is included in this Plan to formally address the monitoring and management of surface water flows and quality within, and flowing out of, the basin. Some work is already ongoing related to this area of concern via a Memorandum of Understanding (MOU) among CLWA, other purveyors within CLWA's service area, and United Water Conservation District, which manages surface water and groundwater in the downstream basins on the Santa Clara River in Ventura County. That cooperative effort, which is incorporated into this Plan via Primary Element 9, includes integration of databases, development of a numerical groundwater flow model, and interpretation and reporting on surface water and groundwater conditions.

A third expressed concern in the basin, although never substantiated, is that groundwater is already overdrafted. Associated with that expressed concern is a related issue that reliance on overdrafted groundwater results in an overstated water supply in the basin. As discussed earlier in this Section, long-term groundwater levels, storage, and quality all indicate a lack of overdraft. As also discussed above, the importation of supplemental surface water over the last 22 years,

The UWMP of 2000 contains incorrect information and is under legal attack for correction. The UWMP does not address the total interruption of the state water supply in the event of drought, earthquake, or Delta problems. It is suggested that the UWMP not be utilized or referred to until its contents have been corrected to reflect accurate and truthful information.

32,000 afy. The history and trend of municipal groundwater use in the basin are illustrated in Figure 4-1.

As noted above, until 1980, all water supply in the basin was from local groundwater. Imported surface water was first available from the State Water Project (SWP) in 1980, when a total of 1,125 af were imported into the basin. Since then, importations of SWP water have increased in two separate steady trends, interrupted by a notable decrease at the end of, and following, the 1987-1992 drought period: a steady increase beginning in 1980, to about 21,600 afy in each of 1989 and 1990, followed by a substantial decrease, to less than 8,000 af in 1991, and then a steady increase back to about 21,000 afy in 1997 and 1998, followed by further increases to about 35,000 af in 2001. The history and trends in importation of SWP water to the basin are illustrated in Figure 4-2, which also illustrates the historical trends in groundwater pumping and total water use in the basin since the importation of SWP water.

In the context of this groundwater management plan, the historical utilization of imported SWP water to augment local groundwater represents the initiation of conjunctive use of surface water and groundwater supplies, a groundwater management principle which is intended to be continued via adoption of Primary Element 5 of this plan.

Projected Water Requirements

Detailed projections of municipal water requirements were most recently completed as part of the Urban Water Management Plan prepared by CLWA and the municipal water purveyors (Newhall County Water District, Santa Clarita Water Company, and Valencia Water Company) in 2000. Those projections, which are forecast for a 20 year period, also recognize an ongoing but decreasing agricultural water demand over the same period, from about 15,000 afy in 2005 to about 7,000 afy by 2020. The municipal water demand projections in the Urban Water Management Plan were derived from utilization and interpretation of multiple projection methods, including Per-Capita Water-Use applied to population projections; extrapolation of number of service connections (using two different projection techniques, an average rate and an accelerated rate projection) applied to the rate of service connection additions since 1990; and land use projections combined with unit water use factors on multiple land use categories (urban, including residential, commercial, industrial and recreational; irrigated agricultural; and vacant and open space). The water demand projections in the Urban Water Management Plan also considered weather effects (variations due to hot-dry years vs. cool-wet years) and conservation

"Local Groundwater" The statement is made: "That for all practical purposes the Saugus Aquifer underlies the entire CLWA service area". That statement is absolutely false! It does not!
Please correct.

Bottom paragraph:
Supplemental (SWP) Surface Water

CLWA's SWP Water Entitlement
The CLWA, indeed, has purchased water in addition to the original Table A entitlement, but cannot obtain contractual agreement to transport the additional water to the Santa Clarita Valley

water and possibly some water supply derived from water transfers and desalination outside the basin.

Local Groundwater - Local groundwater has historically been developed from the two aquifers that comprise the groundwater basin, the Alluvium that underlies the Santa Clara River and its tributaries, and the Saugus Formation that underlies, for all practical purposes, the entire CLWA service area. These two aquifers, and the groundwater basin they comprise, are the focus of this groundwater management plan. Based on historical experience and observation of groundwater conditions, it is currently expected that ongoing utilization of local groundwater will continue to be in amounts that are generally comparable to what has historically been pumped, 30,000 to 40,000 afy from the Alluvium and 7,500 to 15,000 afy from the Saugus Formation. It is also expected that there is some additional development potential in the Saugus Formation, in the range of 10,000 to 20,000 af which might be intermittently extracted during one or more dry years when supplemental imported water might be reduced. Ultimately, it is expected that local groundwater will continue to be a component of water supply, at appropriate production levels in both aquifers, in the basin. The intent of this groundwater management plan is to ensure that ongoing utilization of local groundwater continues to result in acceptable aquifer conditions, i.e. avoidance of overdraft (Primary Plan Element 3), no degradation of quality (Primary Plan Element 6), no adverse impacts to surface waters (Primary Plan Element 2), all via continuation of conjunctive use operations that have been ongoing since the initial importation of supplemental surface water in 1980 (Primary Plan Element 5) and via monitoring and interpretation of surface water and groundwater conditions on an ongoing basis (Primary Plan Elements 1 and 2).

Supplemental (SWP) Surface Water - CLWA has a contractual Table A amount of 95,200 af of water from the SWP. CLWA's original contract, signed in 1963, was for 23,000 af; that Table A amount was later increased to 41,500 af. In 1988, CLWA purchased a Table A amount of 12,700 af from Devil's Den Water District, and it acquired another Table A amount of 41,000 af in 1999 from Kern County Water Agency and its member district, the Wheeler Ridge-Maricopa Water Storage District. There is ongoing CEQA-related litigation over the most recent acquisition of the additional SWP Table A amount, the 41,000 af acquired from Kern County Water Agency and Wheeler Ridge-Maricopa WSD. However, there has been no invalidation of the completed agreement to transfer the 41,000 af Table A amount to CLWA, and current water supply planning includes that Table A amount as CLWA corrects the CEQA technicality by preparing a new EIR to address the environmental consequences of the transfer.

Top:
Recycled Water

It should be noted CLWA's planned recycle water program is and has been for one private business only. No public agency is receiving or is planned to receive recycled water from CLWA.

Recycled Water - In 1993, CLWA prepared a draft Recycled Water System Master Plan that outlined a multi-phase program to integrate recycled water into the overall water supply system in the basin. Construction has begun on Phase I of that project, which will deliver approximately 1,700 afy, and deliveries are expected to begin in 2003. Overall, recycled water is expected to ultimately reclaim up to 17,000 afy of treated waste water suitable for irrigation use on golf courses, landscaping, and other non-potable uses.

4. Provisions to Update the Groundwater Management Plan

Primary Element 1 - Monitoring of Groundwater Levels, Quality, and Production

Prior to 1980, all water supply in the Upper Santa Clara River Area was developed from local groundwater; since 1980, imported surface water has become an increasing component of overall water supply in the area, but groundwater continues to meet all agricultural water demand and a significant part of municipal water demand. As a result of the long term development and use of groundwater in the area, there is a fairly substantial amount of historical groundwater level data, and a useful amount of groundwater quality data, and groundwater pumping data that has been collected in the basin. All the available historical groundwater level, quality, and pumping data have been organized into a computerized data base for the Upper Santa Clara River Area. That data base, while separate, has been coordinated with an equivalent data base maintained by United Water Conservation District for the downstream basins on the Santa Clara River. The intent of database coordination has been to facilitate interpretation and reporting on groundwater and other water resource related issues by the respective agencies overlying the various basins along the River.

Plan, page #28 Dunn, page 11

Bottom:

As stated earlier the UWMP is inaccurate and under legal attack-and not certified by the courts.

Primary Element 4 - Development of Regular and Dry Year Emergency Water Supply

40,000 acre feet from the alluvium and 15,000 a.f from the Saugus is optimistic.

We strongly suggest developing an emergency plan for an extended interruption of the state water project. How many times must we ask for such an obvious safeguard?

conditions (and associated fluctuations in recharge and pumping). Such fluctuations are typical of groundwater basin conditions in any conjunctive use setting, such as in this basin: groundwater is utilized from storage during dry years, or dry periods, and that storage is replenished during alternate wet years, or periods. The observation of these historical groundwater conditions, in combination with knowledge of pumpage from both the Alluvial and Saugus Aquifers, has led to current operational practices as well as general expectations regarding the approximate yield of the local groundwater system as discussed in this plan.

While historical operating experience, complemented by observed groundwater conditions, is an appropriate basis for generally planning for available groundwater supplies, it is possible and appropriate to more precisely analyze the basin to determine values or ranges of yield under varying hydrologic conditions, and to assess the impacts of various management actions that might be implemented in the basin. The MOU process described in Primary Element 9 of this Plan includes the development of a numerical groundwater flow model which is intended to be utilized for determination of the yield of the basin under existing land use and under existing groundwater and surface water development conditions. It is also expected to be used for implementation of this Plan Element in order to assess the yield of the basin under future land use conditions as well as future ranges of surface water importation, groundwater development, and recycled water use through varying hydrologic conditions, i.e. wet and dry periods that affect the availability of imported surface water.

The ultimate intent of this Plan Element is to develop an understanding and quantification of the yield of the basin under varying hydrologic conditions and developing local cultural conditions, in order that groundwater development and use be managed in such a way to meet an appropriate fraction of total water demand while avoiding levels of groundwater use that would result in overdraft conditions. Thus, implementation of this Plan Element is essential to accomplishing the first and second management objectives (goals) for the basin.

Primary Element 4 - Development of Regular and Dry Year/Emergency Water Supply

The most recent updated Urban Water Management Plan (UWMP, December 2000) prepared by CLWA and the other purveyors in the basin (Newhall County Water District, Santa Clarita Water Company, and Valencia Water Company) includes plans to develop 30,000 to 40,000 acre-feet per year (afy) from the Alluvial aquifer and 7,500 to 15,000 afy from the Saugus Formation in average normal years. Both ranges of numbers are consistent with recent historical pumping that

Plan, page #Figure5-4 | Draft, page 12

The SWP water received in 1991 is erroneous. The chart indicates 8,000 af. It is incorrect. CLWA only received 10% of its then allocation 54,200 a.f. The 10% was received in January and the plant shut down in March. See Exhibit A. It should be noted that this is a state water project interruption for months, not a reduction.

Plan, page 430 Draft, page 17

Top paragraph

There is no mention what the folks can do if groundwater cannot meet demand and the supplemental water is not there for an extended period of time. Please develop a plan to solve this most serious occurance.

Conjunctive use of local groundwater and imported surface water will continue to be a key element in meeting all the goals for the basin, most notably utilizing groundwater for water supply without overdrafting the basin. Historical experience with groundwater pumping and aquifer response to varying hydrologic conditions has shown that the groundwater basin can support notable variations in pumping during wet and dry periods, but it cannot support continuous pumping at rates high enough to meet total local water demand. Thus, utilization of imported surface water in conjunction with local groundwater will be essential to the management of groundwater for water supply without overdrafting that resource.

As part of conjunctively using surface water and groundwater, it is recognized that, particularly when the surface water supply is imported from the State Water Project, there will be variations in the amount of available surface water supply from year to year. Similarly, there are expected to be variations in local groundwater conditions as a function of local hydrologic conditions which affect, among other things, the natural recharge to the groundwater basin from year to year. In the case of this basin, local (Southern California) hydrology which affects local groundwater conditions may not necessarily be the same as the hydrology in a distant (Northern California) location that directly affects the availability of supplemental imported surface water in any given year. Thus, conjunctive use management is challenging, but is notably important to ensure that the groundwater basin is maintained to meet a regular component of water supply and to also be able to meet a larger component of water supply during "dry periods" that affect supplemental surface water availability. Conjunctive use management is similarly important to ensure that local groundwater can be replenished, via reduced pumping and/or as a result of wetter local hydrologic conditions, during periods of wet/normal surface water availability. In light of all the preceding, implementation of this Plan Element is essential to accomplishing all the management objectives (goals) for the basin.

Primary Element 6 - Long Term Salinity Management

In general, groundwater quality in the basin is such that groundwater supplies meet standards for beneficial use in the basin, most of which now is for municipal (domestic) use but some of which remains for agricultural and some other irrigation (non-domestic) use. There also have been no notable historical trends of groundwater quality degradation in the basin over time. However, a number of geologic and hydrologic factors suggest that observations and interpretation of groundwater quality warrant some focus to ensure long-term preservation of groundwater quality. Notable among those geologic and hydrologic factors are: 1) the largely "closed" geologic nature

Plan, page #34 Dunn, page 14

Bottom of page:

Is appears the entire paragraph is false. There is no knowledge of such meetings occurring

Newhall County Water District, Los Angeles County Waterworks District No. 36, Valencia Water Company, and its own Santa Clarita Water Division. As such, CLWA has a historical and ongoing working relationship with all those local agencies, as well as with other local groundwater pumpers, to manage water supplies in order to effectively meet water demands within the available yields of imported surface water and local groundwater. In fact, the Advisory Council convened to assist in the preparation of this Plan is comprised representatives of all the local water purveyors and significant groundwater pumpers.

A local MOU process among CLWA, other purveyors within CLWA's service area, and United Water Conservation District in neighboring Ventura County is a classic illustration of a local agency relationship that has produced the beginnings of local groundwater management, now embodied in this comprehensive plan, most notably in Primary Elements 1 through 5. In 2001, out of a willingness to seek opportunities to work together and develop programs that mutually benefit the region as well as their individual communities, those agencies prepared and executed a Memorandum of Understanding (the MOU) that initiated a collaborative and integrated approach to several of the aspects of water resource management that are now included in this Plan. United WCD manages surface water and groundwater resources in seven groundwater basins, all located in Ventura County, downstream of the East Subbasin of the Santa Clara River Valley that is the focus of this Plan. United is thus a logical partner in the cooperation of management efforts to accomplish the objectives (goals) for this basin, particularly as they relate to preservation of surface water resources that flow through the respective basins. As a result of that MOU, the cooperating agencies have integrated their database management efforts (part of Primary Elements 1 and 2 of this Plan), have initiated the development of a numerical groundwater flow model (for utilization in Primary Elements 3, 4 and 5 of this Plan), and are continuing to prepare reports on the status of basin conditions, as well as on geologic and hydrologic aspects of the overall stream-aquifer system.

A local extension of the interaction among CLWA, the retail water purveyors, and United is an ongoing working relationship with the City of Santa Clarita. CLWA and the municipal purveyors meet regularly with City staff and also present water supply conditions via study sessions with the City Council on a regular basis. It is expected that the implementation of this Plan will result in the availability of a broader range of information transfer with the City relative to the existing and future water supply to its residents. OK?

This Primary Element is included in this Plan to formalize the historical local and state agency

Plan, page #35 Dunn, page 15

Middle:

Primary Element 10-Groundwater Management Reports
These secretly created reports contain erroneous numbers to overstate supply and understate demand. The creators meet secretly, allow no public participation or oversight and meet without authority or sanction from any public agency. The meetings are held secretly and without benefit of the Brown Act. Since these reports are created with no public oversight, do not appear to have credibility, and usually are not signed by anyone, they should not be included as part of an AB3030 groundwater management plan. It is time to form an official joint powers authority between the purveyors and other participating parties

working relationships as part of comprehensively managing local groundwater, in concert with imported surface water and local recycled water, to accomplish all the management objectives (goals) for the basin.

Primary Element 10 - Groundwater Management Reports

As briefly described in the Introduction of this Plan, local groundwater management planning already includes, among several other activities, analysis of groundwater conditions and preparation of annual reports on groundwater and all other aspects of water resources and water supplies in the Santa Clara River Valley East ground water basin. In addition, recently formalized cooperative work with neighboring United Water Conservation District includes both regular reporting on the status of groundwater conditions and specific reporting on geologic and hydrologic aspects of the overall stream-aquifer system. For example, documentation of the numerical groundwater modeling work currently in progress is expected to be the first of the latter reports in the next year.

Beginning in 1998, CLWA and the retail water purveyors in the basin have prepared a series of annual reports, known locally as the Water Report, to describe all aspects of water supply and water resource conditions in the basin. That report provides current information to local City and County land use agencies, and to other interested parties, about current water requirements, use of groundwater and treated imported surface water to meet those water requirements, groundwater conditions (pumping, groundwater levels and quality, etc.), local surface water conditions, the status of imported surface water supplies including details of delivered SWP water in the reported year as well as an up-to-date summary of available imported SWP water for the next year, a short-term projection of water requirements in the next year, and other appropriate details about water requirements and supplies such as, for example, the status of introducing recycled water as a component of non-potable water supply.

In light of the frequency and comprehensive nature of the annual Water Reports, and also in light of the planned preparation of more detailed technical reports on various aspects of the basin as appropriate, the continued preparation of those reports will serve as regular and complete reporting on all aspects of this groundwater management plan.

Plan, page 4-16 Draft, page 16

(Not much truth on this page.) CLWA constantly preaches conservation but continually sells more and more water. CLWA should provide the public with an accounting of the water CLWA is conserving.

Secondary Element 1 - Continuation of Public Education and Water Conservation Programs

CLWA has provided water conservation and public education programs that will continue and expand as a complement to and an element of this groundwater management plan. The expansion of water conservation will largely stem from CLWA's having signed the "Memorandum of Understanding Regarding Water Conservation in California" (Urban MOU) in 2001, which made CLWA a wholesaler member of the California Urban Water Conservation Council. CLWA has thus committed to implementation of cost-effective water conservation measures known as Best Management Practices (BMPs) that are included in the Urban MOU and are intended to reduce California's long-term urban water demands. The BMPs have been incorporated into the water demand management measures section of the Urban Water Management Planning Act.

Water conservation and related public education measures have generally been developed in California to achieve the following goals:

- meet legal mandates
- reduce average annual potable water demands
- reduce sewer flows
- reduce water demands during peak seasons
- meet drought restrictions.

As a wholesaler of imported surface water CLWA has implemented the following BMPs for several years prior to signing the MOU:

- distribution system water audits, leak detection and repair
- public information
- school education
- wholesale agency assistance ?
- conservation pricing ?
- conservation coordinator. ?

Plan, page #37 Dunn, page 17

Top:

(Not much truth here either.) Mostly deception. The UWMP doesn't exist for the reasons mentioned earlier. The UWMP must not be considered here.

As a signatory to the MOU, CLWA's water conservation and public education program will expand to include the following BMPs found to be locally cost-effective, as detailed in the 2000 Urban Water Management Plan for CLWA and the Santa Clarita Valley retail purveyors.

- water survey programs for single-family residential and multi-family residential programs
- residential plumbing retrofits
- metering with commodity rates for all new connections and retrofit of existing connections
- large landscape conservation programs and incentives
- high-efficiency washing machine rebate programs (when also provided by local energy providers or wastewater utilities)
- conservation programs for commercial, industrial, and institutional accounts
- wholesale agency programs to financially or otherwise support water conservation efforts by retailers (this measure will be expanded)
- residential ultra-low-flow toilet replacement program.

This Primary Element, while identical to independent CLWA efforts in water conservation and public education, is incorporated in this Plan to complement other Plan elements, and to move toward accomplishment of all management objectives (goals) for the groundwater basin.

Secondary Element 2 - Identification and Management of Recharge Areas and Wellhead Protection Areas

The 1986 Amendments to the federal Safe Drinking Water Act (SDWA) established a new Wellhead Protection Program (WPP) to protect groundwater that supplies drinking water wells for public water systems. Each state was required to prepare a WPP and submit it to the USEPA by June 19, 1989. However, California did not develop an active state-wide Wellhead Protection Program at that time. Subsequently, in 1996, reauthorization of the SDWA established a related program called the Source Water Assessment Program. In 1999, the California Department of Health Services (DHS) Division of Drinking Water and Environmental Management developed its Drinking Water Source Assessment Program (DWSAP), and EPA approved it. The overall objective of the DWSAP is to ensure that the quality of drinking water sources is protected.

As discussed in Section 3 of this Plan, the potential groundwater management plan component

and Hasley Canyon - - does not have a ground-water supply.

The county agency has drilled a well about 1,000 feet northwest of the intersection of Hasley Canyon and Del Valle roads that it had planned on using in about a year after building a 250,000-gallon storage tank, Assistant Deputy Director Gary Hartley said. However, with the new cutback, the county is hurriedly seeking permission from several property owners to run a temporary pipeline from that well to customers, Hartley said.

County officials hope to have the pipeline operating in about six weeks, he said. Meanwhile, the county is working on agreements with the three other purveyors in the valley — the public Newhall County Water District and the private Valencia Water Co. and Santa Clarita Water Co., Hartley said.

If the county cannot set aside enough well water from the other purveyors, there is a chance the state would send emergency supplies through the Castaic agency, he said.

While the city considers a law that would restrict wasteful practices in the hopes of achieving a 25 percent reduction in water use, Hartley said that county water officials are drafting a conservation proposal that would require different levels of participation in different areas. Because of the severity of the water cuts in the Val Verde and Hasley Canyon areas, he said he would expect a 20 percent to 30 percent mandatory cutback in water use.

Although the plant near Castaic Lake will be closed, the agency most likely will lay off just a temporary maintenance worker, Sagehorn said. The worker was hired when one of the two permanent maintenance workers was on medical leave and was kept on.

Suppliers driven into the ground

Drought forces area to rely on well water

2-27-91

By Kimberly Heinrichs
Daily News Staff Writer

SANTA CLARITA — The state is expected to stop water deliveries March 15 in the Santa Clarita Valley, forcing the area to rely on ground water as California's worst drought on record continues, officials said Tuesday.

The Castaic Lake Water Agency, which treats, stores and distributes state water to local purveyors, will close its plant after the last of the imported water arrives, agency General Manager Robert Sagehorn said.

Related story:
■ Conservation law gets OK.
Page 4

"For all substantial purposes we're shutting the plant down on March 15," he said, adding, "No one's going to go bone dry over this."

Local water suppliers still will pump water from the Santa Clarita Valley's extensive network of wells, he said.

The state Department of Water Resources told Sagehorn on Saturday that the expected cut of 50 percent of the agency's water supply has been increased to 90 percent as the drought continues its fifth year. The agency will have received 10 percent of this year's water allocation by the middle of March, Sagehorn said.

Of the four purveyors receiving state water from the Castaic Lake agency, only the Los Angeles County Waterworks District No. 36 -- which serves Val Verde

Officials say state's water delivery system inadequate

By Laura Myers
Associated Press

MONTEREY, Calif. — The top [illegible] for many years in California because of an inadequate water delivery system, representatives of the three main groups vying for the precious commodity concluded Thursday.

The 5-year-old drought that has [illegible] when supplies were drastically cut only magnified the problem this year, said representatives of the urban, agriculture and wildlife interests.

"The biggest problem we have is that the reliability of the water supply is grossly inadequate," said Tom Quinn, conservation director for the urban Metropolitan Water District of Southern California. "The way the system works now, people can't count on a steady water supply because the water delivery system just doesn't work like it should."

Quinn's comments came at the annual spring conference of the California Association of Water Agencies, which attracted more than 2,000 of the state's top water officials.

Stephen Hall, representing agriculture, and Charles Hanson, representing wildlife and the environment, agreed with Quinn that the State Water Project and the federal Central Valley Water Project can't [illegible] competing water needs.

All three men presented dire pictures of what would happen if there weren't the [illegible] for water if the drought continues — the [illegible] of urban life will decline, farms will go under, workers will be jobless and wildlife will dwindle with some species becoming extinct.

But beyond the present drought competition for scarce supplies, they said water officials must improve the delivery and storage system that essentially hasn't changed in decades.

"We shouldn't have to continue to fight one another for resources," said Hall, executive director of the California Farm Water Coalition.

The Sacramento-San Joaquin Delta, the cornerstone of the delivery system, is a bottleneck even in non-drought years, Quinn and Hall said.

Part of the problem, according to Hanson, who has an environmental consulting business, is the growing importance of protecting endangered and threatened species while making water transfers in the delta.

The winter-run chinook salmon already is listed by state and federal wildlife officials as threatened and the delta smelt also is expected to [illegible] the U.S. Fish and Wildlife Service list soon.

Certain water flow rates [illegible] when these fish spawn under wildlife guidelines, he said.

"We need to manage the delta [illegible] to provide adequate water throughout the year," Hanson said.

EXHIBIT C

A boost for toxic cleanup in state

Feds back state on perchlorate

By Heather MacDonald
Staff Writer 8-8-03 D. N.

SANTA CLARITA — The Department of Defense agreed Thursday to obey California's drinking water standards for perchlorate and not try to avoid paying for cleanup of the toxic rocket fuel byproduct.

The agreement, announced by U.S. Sen. Barbara Boxer and Pentagon officials during a visit to a contaminated site in Rialto, could help speed the cleanup of the defunct Bermite explosives factory in the center of Santa Clarita, and dozens of other polluted sites all over California, officials said.

"This is an important breakthrough," said Boxer, a California Democrat. "Defense Department activities have been a major source of perchlorate contamination in California. This kind of active cooperation will help us find and fix perchlorate problems throughout the state."

The agreement also appeared to put to rest concerns expressed by Santa Clarita leaders that legislation introduced by President George W. Bush would exempt some defense contractors from having to pay for environmental cleanups in the name of military readiness.

The Newhall County Water District Board of Directors was afraid the language of the bill could be used to let Whittaker Corp., which operated the site until 1987 and has recently begun studying the best ways to clean up the pollution, off the hook.

"The well-being of millions of Californians depends on this agreement," Boxer said.

More than 7 million Californians drink water with at least traces of perchlorate, which can damage the thyroid gland and be risky for pregnant women, whose fetuses can be affected, according to the U.S. Environmental Protection Agency.

A provisional standard set by the EPA recommends that drinking water have no more than 1 part per billion of perchlorate. The old standard considered water with 32 parts per billion of perchlorate safe.

Although the EPA is not expected to set a final standard

See WATER / Page 2

Help on the way for toxic cleanups

8-8-03 DN

WATER / From Page 1

until at least 2008, Boxer has called for the agency to act next year because of the threat perchlorate poses to California residents.

Five wells in Santa Clarita have been shut down because of high levels of perchlorate, with tests showing as much as 40 parts per billion of the toxin in the water, officials said. The wells draw on the Saugus Aquifer, which serves as a backup water supply for the Santa Clarita Valley in times of drought.

State officials believe the pollution is coming from the Bermite property near the Santa Clarita Metrolink Station on Soledad Canyon Road. From World War II to the end of the Cold War, several companies manufactured and tested munitions and explosives for the U.S. military on the 996-acre site.

While the California Department of Health Services requires that wells with more than 4 parts per billion of perchlorate be shut down, the state Office of Environmental Health Hazard Assessment has found that water with as much as 6 parts per billion is safe to drink.

Subject: Draft Groundwater Management Plan

TO: Dan Masnada

RE: Draft Groundwater Management Plan

Following are my questions and comments related to the Agency's Draft Groundwater Management Plan:

1. What percentage of the 106,000 afy (needed over the next 20 years) will be drawn from local groundwater sources? Does the Agency expect to maintain roughly the same 60% SWP/40% local groundwater mix in most years?

2. If the Saugus Formation absorbs recharge much more slowly than the Alluvial Aquifer, won't pumping of the Alluvial Aquifer at the high end of the scale over a sustained period of time reduce recharge of the Formation and reduce the amount of potable water that can be drawn from the Formation in dry periods?

3. Both this report (p. 15) and the 2002 Water Report (p. 19) state that the Agency does not have sufficient groundwater quality data on the Saugus Formation to perform an analysis of "pumping related inpacts on quality." On page 25 of this report under Primary Element 1, the Agency states that it has "a useful amount of groundwater quality data." Is the latter in reference only to the Alluvial and not the Saugus? And if the Agency does not have sufficient data on quality of water from the Saugus Formation, how does the agency propose to collect that data to ensure quality in order to maintain the current pumpage level and to increase the yield as proposed on page 21?

4. Looking back at the 2002 Water Report, the Agency indicates (on page 19) that "there are limited Saugus (Formation) water level data." Does the Agency plan to collect more comprehensive data on the Saugus Formation general groundwater stability to determine reliability of projected yields and "artificial groundwater recharge" (p. 27) capacity?

5. Regarding Secondary Element 2, the Agency states: "The results of the DWSAPs can be used as a planning tool to guide land use development in the vicinity of water sources." Is the Agency currently sharing more recent, detailed information with the City regarding contamination risks in relation to the existing closed wells?

6. Where is the SCWC Stadium Well located?

7. Why is "Continuation of Public Education and Water Conservation listed as a Secondary (Potential) Element" when increased conservation savings are projected to reduce water demand by 10%? Shouldn't conservation be one of the primary elements of water management?

8. How is the Agency delivering recycled water to the TPC? Is it being run through a parallel piping system? Is so, what is the estimated cost and time frame for constructing such a system to carry the estimated 17,000afy? And how does the Agency propose to pay for this system?

9. How is the recycled water in locations, such as the golf course, reprocessed to remove pesticides and fertilizers?

10. What is the current average per capita water usage in afy?

11. The Semitropic Water Bank/Transfer is not mentioned in discussion of the Supplemental (SWP) Surface Water on page 21. Is that because it is a relatively short-term water supply? Are any of the other water transfers – Kern Water Bank, Kern Delta Water, North Las Posas Water Bank – as listed on UWMP p. 2-16, of limited duration? And if the Semitropic Water Bank Transfer is short term, how can it be included in the 105,000-106,000 afy need projected for the next 20 years? What will take its place?

12. What specific efforts will be made to manage salinity?

Thank you for giving me an opportunity to respond.

Diane Trautman

Responses to Trautman

1. In terms of groundwater management planning, projected urban water demand (the 106,000 afy projected urban demand in 2020) does not represent total valley-wide demand; total projected demand is 113,100 afy, including both urban and agricultural. In that light, on an average basis, local ground water is expected to be utilized to meet about 40 percent of total water demand.

   In regards to maintaining "roughly the same 60% SWP/40% local groundwater mix in most years", please refer to page 20 of the draft GWMP for a more complete response to your question. For example, about 54 percent of water demand in 2001 was supplied by local groundwater, and about 46 percent was supplied by imported SWP water. Also please refer to Table II-5 in the 2002 Santa Clarita Valley Water Report, which displays the build up of SWP water use through time, and the relative percentages of groundwater and SWP water used in a given year. As noted above, it is expected that, over time, again on an average basis, the annual amount of local groundwater pumping will not appreciably change but its fraction of total water supply will decrease. Conversely, over time, and once again on an average basis, both the annual volume of imported SWP water and its fraction of total water supply will increase.

2. No. Since the Saugus Formation is recharged over a much larger area, beyond the spatial extent of the Alluvium. There is a limited relationship between Alluvial pumping and recharge to the Saugus Formation.

   The fundamental tenet of the GWMP is to utilize groundwater for water supply within its sustainable yield (see the Management Objectives, or Goals, for the Basin, GWMP Section II; see also the various GWMP Elements intended to achieve those objectives, GWMP Section V). In that light, it is expected and intended to operate in such a way that recharge to the Saugus Formation will not be "reduced" by pumping from the Alluvial Aquifer and that groundwater will be available in varying amounts, as needed depending on weather year-types, within the sustainable yields of the respective aquifers (i.e. without overdrafting them).

3. The reference to "useful amount of groundwater quality data" in the GWMP includes both Alluvial and Saugus data. However, due to the historically greater development and use of groundwater from the Alluvium (number and distribution of wells, volume of pumping), and due to the historically smaller development and use of the Saugus Formation (fewer wells, smaller geographical distribution of wells, smaller pumpage), there is a comparatively limited ability to examine relationships among pumping, recharge, and quality in the Saugus. CLWA and the other purveyors intend to expand the overall knowledge of the Saugus Formation as that resource is further explored and

developed (number of wells, additional sampling as new wells are added, etc.). All that data will be included in ongoing implementation of GWMP Primary Element 1, Monitoring of Groundwater Levels, Quality, and Production.

4. The "limited nature of Saugus water level data" is a result of the same smaller extent of historical Saugus development described in the preceding answer. Acquisition of additional data on the Saugus Formation is planned as also described in the preceding answer.

5. All publicly available information regarding the investigation of perchlorate contamination, its extent, its impact on water supply, and plans for cleanup, control of migration, etc. is available to the City. Representatives of CLWA and the purveyors meet routinely with City representatives to review the status of perchlorate cleanup and remediation activities. CLWA and the impacted water purveyors will continue to pursue control and cleanup of perchlorate contamination in order to restore impacted groundwater pumping capacity and to ensure the long-term quantity and quality of groundwater in accordance with the GWMP. As a practical matter, there are no surface contamination risks relating to perchlorate that would affect land use development adjacent to the wells.

6. The stadium well is located on the south side of the Santa Clara River, approximately two miles upstream (east) of its confluence with the South Fork tributary, or about 4,000 feet east of the Bouquet Canyon Road crossing of the Santa Clara River.

7. The assignment of "primary" or "secondary" status to any GWMP element is discretionary and certainly not absolute. Secondary status is not intended to indicate that any element of the GWMP will not be implemented; all elements are intended to be implemented. Final status of all GWMP elements will be reviewed by the Advisory Council and decided by the CLWA Board.

8. Recycled water is being delivered to the TPC via the dedicated, recycled water distribution system, which is also capable of delivering water to other non-potable water users, and which will be expanded in accordance with the Draft Recycled Water Master Plan. The costs and time frame for expanding recycled water distribution and use are included in the Draft Recycled Water Master Plan, which is complementary to, but beyond the scope of the Groundwater Management Plan. The intent is to develop the 17,000 AFY of use by 2020. The capital cost of the complete system is estimated to be $68 million, and will be funded through CLWA's connection fee program.

9. Recycled water is not "reprocessed" at points of use such as the TPC golf course. In general, recycled water is highly treated (tertiary treated) waste water. In the case of the Santa Clarita Valley, treatment already occurs at the Valencia Reclamation Plant operated by the Sanitation Districts of Los Angeles County. The treated water, ready for non-potable use, is distributed from the plant site in a dedicated transmission pipeline system to end users such as the TPC. Pesticide and fertilizer uses, as part of cultural practices at end-user locations such as golf courses, are discretionary actions of the respective end users of recycled water.

10. Most water agencies no longer use "per capita" water use as a standard because it is not an accurate representation of actual per person water use, mainly due to the effects of landscape and commercial industrial water use. (It is also expressed in "gallons per day," rather than "acre-feet per year, since it refers to individual water usage.") In general for the South Coast hydrologic region of California, water use is approximately 200 gallons per person per day (DWR Bulletin 160-98). Per capita use for the Santa Clarita Valley is slightly higher than this due to landscape irrigation demands caused by local climatic conditions.

11. The SWP is referred to as "supplemental" water because that is the original purpose of the SWP: to serve as a supply that would "supplement" local supplies (whether groundwater or local surface water or both). The specific amounts referred to in the GWMP are from the contractual terms between CLWA and the California Department of Water Resources.

    The water banked in the Semitropic Water Storage Program during 2002 is a short-term, dry period supply. The program has a term of ten years (i.e., the water must be returned to CLWA for use in its service area within that time period). Thus it is not included as a supply for long-term needs. However, the other programs listed in the UWMP (most of which, by the way, are not water "transfers," but are instead groundwater banking programs) are long-term sources of supply. As of this writing, the Agency is in the process of designing and implementing a Long-Term Reliability Plan to begin bringing such long-term programs on line as a means to store water available in wet years, for use in later dry years. CEQA analysis, with its accompanying public comment opportunities, will be part of the long-term reliability program approval process.

12. Primary Element 6 – Long Term Salinity Management is included in the GWMP for the reasons presented in the text discussion of that element. The element recognizes the need to plan for salinity management but also recognizes that, to the present, there has been no extraordinary trend of salinity increase. Hence, there are no specific efforts currently in place to "manage" salinity. It is envisioned that specific efforts will be developed over

time in response to implementation of the GWMP and, in particular, its Primary Element 6.

CLWA is participating in efforts by the Sanitation Districts of Los Angeles County to address the Los Angeles Regional Water Quality Control Board's proposed TMDL standard for chloride in the Santa Clara River. This effort is separate from and beyond the scope of the Groundwater Management Plan.

Re: Groundwater Management Plan (AB 3030) Nov. 2003 Draft

Dear President Kavounas and Directors:

We would like to comment on some statements of your new draft plan. On page 38 there is a bullet - Conservation pricing. Since we have never seen any conservation pricing locally, this should be explained or removed. We seriously question this being presently implemented.

On page 41, we ask why you are stating that only the eastern portion of the alluvium has experienced historical fluctuations in groundwater levels. How can there be constant groundwater levels in the western portion of the basin, when the western basin is supposed to receive its re-charge primarily from the eastern portion of the river? You imply that tributaries in the Bouquet Canyon area are the source of water in that area. We believe you are avoiding the real source of water to the area. That source appears to be the large amount of effluent from Sanitation District #26, and is maintaining the water level. Why is this not explained?

As usual, there is no explanation for a total extended interrupt of the state wholesale water system or the CLWA facilities!

We are disappointed that of the numerous comments of August 8, 2003 that we supplied, only a few were considered. We spent our time and efforts to supply comments and suggestions to make the water plan a good plan. So much for that!

Sincerely,

Ed and Joan Dunn

Subject: November 25, 2003 Groundwater Management Plan Protest Hearing

I will not be attending the protest hearing this evening, but I do have three comments on the materials you provided to me.

First, I commented previously on the proposed network of monitoring wells and the public availability of data. The monitoring wells in figures 5-1 and 5-2 appear to cover a wide range of the valley. However, the text on p. 27 states the network will be "mostly as illustrated in figures 5-1 and 5-2, but possibly expanded." I hope the final network is extensive and covers all areas of the valley. Further expansion of the network would add valuable data points and should be encouraged.

I did not see any indication of whether the collected monitoring data would be publicly available. I have heard comments from others that some well data is not being released to the public, even upon request. I think that concerned citizens and groups should be allowed access to the monitoring database.

Second, I have one new comment on the wording on page 34 regarding perchlorate cleanup. The last paragraph states "the proposed pumping would be combined with approved wellhead treatment to render the treated water suitable for municipal supply." This may be a wording issue, but my understanding is that wellhead treatment is not always approved or allowed by the permitting agencies. This wording implies that wellhead treatment is already an approved scenario, while it may be determined that treatment followed by re-injection or non-potable usage makes more sense. I think it would be more accurate to not specify the final treatment scenario until the plume characterization is complete and the pilot studies are finished and accepted.

Finally, the plan is clearly an overview that will have to be expanded upon with supporting policies and target dates. Some commentors requested this information go in the groundwater plan. If the agency does not add implementation strategies and target dates to the plan, they should be prepared separately, updated annually, and made available to the public upon request.

I understand the time for commenting may have past, but if you are able to address these concerns in the final draft, I would be appreciated.

Sincerely,

Maria Gutzeit

Memorandum of Understanding Between the Santa Clara River Valley Upper Basin Water Purveyors and United Water Conservation District, August 2001

MEMORANDUM OF UNDERSTANDING
BETWEEN THE
SANTA CLARA RIVER VALLEY
UPPER BASIN WATER PURVEYORS
AND
UNITED WATER CONSERVATION DISTRICT

AUGUST 2001

COPY

Memorandum of Understanding
Between the
Santa Clara River Valley
Upper Basin Water Purveyors and
United Water Conservation District

August 2001

MEMORANDUM OF UNDERSTANDING

This Memorandum of Understanding ("MOU") is entered into effective August 20, 2001, by and among Castaic Lake Water Agency ("CLWA"), CLWA's Santa Clarita Water Division ("SCWC"), Newhall County Water District ("NCWD"), Valencia Water Company ("VWC") and Los Angeles County Waterworks District No. 36 ("LACWD"), which are collectively referred to as the "Upper Basin Water Purveyors" and United Water Conservation District "UWCD", hereinafter referred together as the "parties."

RECITALS

WHEREAS, UWCD is a public agency that encompasses approximately 214,000 acres of land located in central Ventura County. UWCD's service area covers the downstream portion of the Santa Clara River Valley in Ventura County, as well as the Oxnard Plain (sometimes referred to as the "Lower Santa Clara River Area"). UWCD manages surface and groundwater resources within seven groundwater basins in the Lower Santa Clara River Valley Area. UWCD's Boundary is shown on Figure 1-1; and,

WHEREAS, the Upper Basin Water Purveyors meet regularly as a technical group to coordinate conjunctive use of imported, recycled and groundwater resources of the water basins east of the Los Angeles/ Ventura County line (sometimes referred to as the "Upper Santa Clara River Area"), which is located almost entirely within northwestern Los Angeles County. The respective services areas of the Upper Basin Water Purveyors members (CLWA, SCWC, NCWD, VWC and LACWD) are shown on Figure 1-2; and,

WHEREAS, UWCD has been involved in the review of water resources in both the Lower Santa Clara River Area and also the Upper Santa Clara River Area as part of UWCD's review of the Newhall Ranch Specific Plan and EIR (NRSP); and,

WHEREAS, litigation of the Newhall Ranch Specific Plan and EIR resulted in preparation of an additional analysis to the previously certified EIR for the NRSP, including the section addressing water resource issues; and,

WHEREAS, the Additional Analysis includes a water flow model and impact analyses of the future water usage projections for the Upper Santa Clara River Area; and,

WHEREAS, UWCD, Newhall Land and Farming Company (NLF) and others have had several technical meetings to further study the Additional Analysis as it relates to the water issues, and, based on this information, and further discussions between UWCD and the Upper Basin Water Purveyors, UWCD believes that it is in the best interests of the parties and the future beneficial water resources management in the upper and lower basins to enter into a cooperative working relationship among the parties; and,

WHEREAS, the parties have determined that this MOU is the best format for establishing a program that would be implemented over time for purposes of agreeing upon overall water resources management techniques and an information database that would benefit the upper and lower basins; and,

WHEREAS, this MOU is prepared by UWCD and the Upper Basin Water Purveyors because the parties believe that a cooperative water resource monitoring program in the Upper and Lower Santa Clara River Areas is desirable to protect and enhance the conjunctive use of imported water, groundwater and surface water resources within the region; and,

WHEREAS, the parties support regional water planning efforts that rely on the provision of accurate and timely information about available water resources; and,

WHEREAS, the parties to this MOU desire to create and maintain a cooperative relationship for purposes of gathering information for UWCD and the Upper Basin Water Purveyors to be used in further assessing imported water, surface water and groundwater conditions in both the Upper and Lower Santa Clara River Areas; and,

WHEREAS, the parties to this MOU intend to form a reciprocal relationship. In order to do this, UWCD will designate an individual or individuals with technical knowledge and experience appointed by the General Manager of UWCD who will be included in discussions and efforts that take place with the Upper Basin Water Purveyors and others regarding the Upper Santa Clara River Area. Likewise, the Upper Basin Water Purveyors will designate an individual or individuals with technical knowledge and experience appointed by the General Managers of the Upper Basin Purveyors who will be included in discussions and efforts with UWCD and others regarding the Lower Santa Clara River Area, and,

WHEREAS, the goal of the MOU is to establish a joint monitoring program, which includes: (a) data collection (monitoring and testing); (b) database management; (c) groundwater flow modeling; (d) assessment of groundwater basin conditions (operational yield); and (e) report preparation and presentation.

NOW, THEREFORE, in consideration of the mutual promises and covenants herein contained, the parties to this MOU agree as follows:

1.1 **Program Monitoring.** The parties will participate in a joint monitoring program.

1.2 **Program Content.** The technical aspects of this joint monitoring program are set forth in a technical memorandum entitled, "Water Resource Monitoring Program Upper Santa Clara River Area," (Program) which is attached as Exhibit 1 and incorporated by this reference.

1.3 **Program Meetings.** The General Manager or President of each party to this MOU (or their designee) shall meet as the "Program Committee" within 30 days of the execution of this MOU. The "Program Committee" will establish appropriate subcommittees to initiate the Program and determine the meeting times and locations for the committees. The Program Committee and subcommittees will discuss and coordinate technical aspects of the Program, including the gathering, interpretation and reporting of information as outlined in the technical memorandum (Exhibit 1). Other attendees may be permitted by agreement of the parties to this MOU.

1.4 **Monitoring Costs.** The costs incurred in administrating the Monitoring Program will be determined as implementation of the Program takes place. However, it is understood that, unless the parties to this MOU agree otherwise, the Upper River monitoring costs of the program will be borne by the Upper Basin Water Purveyors because such monitoring will take place within their service areas and the Lower River monitoring costs of the program will be borne by UWCD because such monitoring will take place within its service area.

1.5 **Program Implementation**. The parties to this MOU have prepared a schedule, attached as Exhibit 2, that describes the tasks and estimated time to implement the Program. The Parties acknowledge that Program Implementation will be an on-going and evolving process and may change due to future amendments to the Program, challenging technical issues or other unforeseen circumstances.

1.6 **Water Rights**. Notwithstanding the provisions of this MOU, nothing in either this MOU or the technical memorandum (Exhibit 1) shall be construed as affecting the water rights or operations of any party, person or entity.

1.7 **Term.** This MOU shall remain in effect for an initial period of seven (7) years and shall be automatically renewed for additional one year increments unless otherwise unanimously terminated by the members of the Program Committee as that committee exists at the time action is taken to terminate this MOU.

1.8 **Counterparts.** This MOU may be executed in any number of counterparts, each of which, when so executed, will be deemed to be an original and all of which taken together will constitute one and the same agreement.

IN WITNESS WHEREOF, the parties have executed this MOU as of the date first set forth above.

WATER RESOURCE MONITORING PROGRAM
UPPER SANTA CLARA RIVER AREA

INTRODUCTION

As part of its ongoing monitoring, interpretation, and reporting on imported water supplies and groundwater conditions in the aquifer systems underlying the Upper Santa Clara River Area, generally east of the Los Angeles County - Ventura County line and extending east to about the vicinity of Lang Station, the principal water purveyors in the area (primarily the municipal water purveyors - Castaic Lake Water Agency, Los Angeles County Waterworks District No. 36, Newhall County Water District, and Valencia Water Company) have committed to formalizing the data base on which water supply conditions are analyzed, and expanding the analysis of groundwater conditions such that the adequacy of water supply is well understood, and that both local and regional questions or issues about surface and groundwater can be addressed.

This water monitoring program outline has been prepared as a cooperative effort by the Upper Basin Water Purveyors operating in the Santa Clarita Valley and by the United Water Conservation District in Ventura County, the latter as the primary groundwater resource management entity in the Lower Santa Clara River Area (west of the Los Angeles - Ventura County line). The intent of the program outline is to delineate a series of elements that will be undertaken primarily by the Upper River Area entities, but in cooperation with United such that there is ultimately an integrated and coordinated data base, as well as agreed-upon technical tools such as a numerical groundwater flow model, to allow a continued regional understanding of water resources along the Santa Clara River. In that light, the following program includes elements which address data collection (monitoring and testing), database management, groundwater modeling, operational yield analyses, and report preparation and presentation.

DATA COLLECTION (MONITORING AND TESTING)

Historically, data on groundwater and related hydrologic conditions have been collected on varying frequencies and in varying formats throughout the Upper River Area. Fortunately, more than sufficient data have historically been collected on groundwater levels, quality, and production (pumpage) to permit general assessment of groundwater conditions, in some detail in the widely developed Alluvial aquifer and to a lesser extent the Saugus Formation aquifer. In order to expand on the general assessment of groundwater conditions, historical data collection efforts will be updated and formalized in the following areas.

Groundwater Levels and Quality - Wells in which historical and current water level data are available will be "qualified" (to confirm locations, depths, well completion details, annular seals, etc.) to confirm their utility for ongoing monitoring of water level and/or water quality in a particular aquifer. Based on a combination of qualified well details and available historical and current data, a network of existing and future wells will be developed for ongoing monitoring of groundwater levels (initially on a semi-annual frequency) and groundwater quality (initially on an annual to triennial frequency, depending on the use of the well) in both the Alluvium and the Saugus Formation aquifers. The water level and water quality monitoring networks may not be identical (as with most basins, the number of water level monitoring points will likely be greater than the number of water quality monitoring points). Also, in light of the relative differences in development of the two aquifer systems, there will be more monitoring points in the Alluvium than in the Saugus. However, as future development of the Saugus increases, particularly as the spatial extent of the Saugus "well field" expands, the Saugus monitoring network will evolve and expand accordingly. Water quality details are expected to begin with what historical analyses have been made; monitored details are expected to increase as the use of local Groundwater continues to change from irrigation supply to municipal supply, with the addition of organic and other hazardous chemical analyses of drinking water supplies in recent years. Finally, such as any dedicated monitoring wells are installed in the area, for specific site investigation or other purposes, they will be added to the qualified well network as appropriate.

Groundwater Pumpage - Essentially all pumpage in the Upper Area (except small capacity individual domestic and similar wells) is metered or directly estimated from electrical power records, and the results are maintained in a decentralized data base. Metered measurement of all substantial capacity wells (all municipal and agricultural, as well as other private wells, e.g. golf course irrigation wells) will be continued on at least an annual basis, with progression to monthly data collection as appropriate for particular analyses that may be undertaken.

Surface Water Flows and Quality - Historical stream gage sites will be preserved as possible to allow ongoing surface water gaging of stream inflows to the Upper River area, stream outflows from the Upper River area into Ventura County, and return flows to the River system from in-area wastewater treatment plant discharges. Surface water quality at the same points will also be sampled on some frequency to continue historical records as appropriate or to document episodic or other (e.g. treated wastewater discharges) surface water flows into or out of the Upper River area.

Well and Aquifer Characteristics - Recently constructed wells, in both the Alluvium and Saugus Formation, have been tested, in some cases with the benefit of nearby monitoring wells, to determine well yields and aquifer hydraulic properties (e.g. transmissivity and storage coefficient). In limited cases, production logging and depth-specific water quality sampling has been undertaken to examine variations in aquifer productivity and quality with depth. Such as there is a need for additional spatial or vertical distribution of well yield or aquifer characteristic data, selected qualified wells will be tested in the Alluvium and Saugus aquifers. In general, all new production wells will be tested to determine the yields of the wells and the hydraulic characteristics of the aquifer materials in which they are completed at various locations in the Upper River area.

Precipitation - The locations of historical precipitation gaging will be verified and the quality of the gaging stations will be assessed. Continuation of historical gaging will be a primary goal, with additions as appropriate to assess inflow of water within the Upper River area as well as distribution of precipitation throughout the area.

DATABASE MANAGEMENT

Geographic Information System - There is a good start on a regional GIS from the US Geological Survey's Regional Aquifer Study. For instance, roads, streams and other basic geographic features are in the USGS GIS that has been maintained and expanded by United Water Conservation District. United has commercial digital air photo coverage of Ventura County that includes a small portion of western Los Angeles County; additional digital imagery will be sought from agencies in Los Angeles County.

Most of the wells in the Valencia/Santa Clarita area are also in a USGS GIS coverage that includes well construction information. The wells are identified by owners designations as well as state well number. By using the state well number in identifying all monitoring data, information from the databases can be linked directly to the GIS well coverage.

Water Level Database - Monitoring data will be collected together in common databases, using an easily accessible program such as Microsoft Access. Groundwater level information is presently in a variety of forms, including paper copy, spreadsheet files, and agency databases. The digital information will be incorporated into a master database, but the data on paper copies will have to be entered into a computer. This will be accomplished by prioritizing the order in which this information is entered. Historic groundwater level data will be obtained from as many wells as possible, public and private, to ensure meaningful area coverage.

Water Quality Database - Water quality information may be a larger chore to organize in a database than water levels because each water sample collected is commonly analyzed for a large number of constituents. For water quality data collected in the future, analytical labs can provide results in digital form for ease of integration into a database. Historical water quality information is available digitally from the California Department of Health Services for public water supply wells (data is available for about the past ten years). For the rest of the historical water quality data, prioritizing the order of manual data entry would be necessary. Constituents of concern are obviously the first to be entered. Whether to enter all historical data will need to be addressed; this information is valuable in identifying long-term trends, but data entry takes time. United Water now has all historic water quality data for seven basins in Ventura County in a database, but it took several years to do this.

Water quality data from surface sources such as streams will also be included in the main water quality database. A location identifier can be used to tie the sample to the monitoring location in a GIS coverage. The approximate flow of the surface water source at the time of measurement should accompany each water quality data entry.

Pumpage Database - Pumpage data from individual wells is key to assessing both water level and water quality trends. This information is also required to construct a groundwater model. Some of this information has already been entered in computer files and can be readily imported into a database. Other information will likely have to be obtained on a cooperative basis. If pumpers do not have their own metered pumping records, pumpage will be estimated from other sources such as utility bills. For wells where no records have been kept, probable pumping quantities can be estimated through land use records and, in the case of irrigated agriculture, from irrigation methods and practices. This calculated information should not be entered directly in the pumpage database.

Streamflow Database - There should be a database of streamflow measured at various monitoring points. For USGS gauges, much of this information is already in digital form. Other agencies, such as County Flood Control, may also have digital data.

GROUNDWATER FLOW MODELING

As part of the technical analysis of water supply alternatives to meet projected water demands of the proposed Newhall Ranch project in the Upper River area, a numerical groundwater flow model was prepared for that project's proponent. That model was developed to focus on the feasibility and impacts of a potential storage and recovery project in the Saugus Formation, including the impacts of injection and recovery pumping in the Saugus on the overlying Alluvium, and the resultant impacts on Santa Clara River flows out of the Upper River area. The current model is calibrated for a steady state condition, including the addition of some focused injection and pumping. As a result, it represents a useful initial modeling effort of the overall aquifer system in the Upper River area. Depending on its availability for other uses in the Upper River area, that initial model will be subjected to transient calibration efforts and additional calibration of the Alluvial aquifer. The model will then become an evolving tool for analysis of ongoing groundwater development and recharge, in conjunction with imported surface water, and the resultant impacts on groundwater conditions in the Upper River area, as well as on surface outflows to the downstream basins on the Santa Clara River.

OPERATIONAL YIELD OF THE BASIN

A primary objective of the monitoring efforts, database management efforts, and modeling efforts described above is to assess groundwater basin conditions in the Upper River area in the context of the long term sustainability of the Alluvium aquifer and the generally underlying Saugus Formation, and to operate the basin such that the operating yield is not exceeded over a multi-year wet/dry cycle. This operational yield includes flexibility of groundwater use by allowing increased groundwater use during dry periods and increased recharge (direct or in-lieu) with supplemental water when it is available. The operational yield protects the aquifer by assuring that groundwater supplies are adequately replenished from one wet/dry cycle to the next. Historical groundwater data demonstrates that the Alluvium has been, and continues to be developed within its long-term sustainability (i.e. no chronic lowering of water levels, no notable trend toward degradation of groundwater quality, etc.). Limited historical data in the Saugus Formation shows no lowering of water levels or degradation of water quality where it has been developed.

While current planning places future pumping of the Alluvium in the same range as has historically occurred for several decades, with anticipated similar results in terms of Alluvial water levels, storage, and quality, the model described above will be a useful tool to quantify the impacts in water budget terms and to analyze a range of scenarios as appropriate to optimize the use of the high-yielding Alluvium. The Saugus Formation is alternately being considered for short-term dry-period water supply at capacities higher than have historically been pumped from that formation, and for injection, storage and recovery of water as part of the overall water supply of the Upper Santa Clara River area. The model will also be used to determine the operational yield of the Saugus under a wide-ranging set of low to high pumping capacities (during wet to dry years, respectively), and with varying aquifer storage (recharge), to avoid undesirable impacts and assure that the operating yield is not exceeded over a multi-year wet/dry cycle.

REPORTING

Beginning in 1998, an annual report on water supply conditions in the Upper Santa Clara River area has been prepared by the water purveyors in the Upper River area. Those reports have focused on a planning-level discussion of current and immediate future water demands, and the availability of local Groundwater and imported surface water to meet those demands. The overall primary objectives of the reports have been to provide some documentation, to local and County planners as well as County Supervisors, on the water supply conditions in the Santa Clarita Valley and to present a general assessment of the status of groundwater conditions in both the Alluvial and Saugus aquifer systems, with a focus of that assessment on historical and recent groundwater development within operating yield parameters.

As the water resource monitoring program described above is implemented and evolves, it is planned that reporting on groundwater basin conditions will evolve in two generally parallel ways: 1) a continuation of the annual reporting on current water supply conditions, as a basis for current planning and consideration of development proposals; and 2) the addition of less frequent, more technically oriented reports on the geologic and hydrologic aspects of the groundwater resources of the Upper River area, including documentation of: a) groundwater basin conditions, b) development and application of modeling efforts to assess operational yield and the impacts of long-term planned utilization of local groundwater as part of the overall water supply, and c) assessment of actual versus predicted impacts on groundwater and surface water, including basin outflows, combined with ongoing updated assessments of the adequacy of local groundwater management actions and identification of any needed changes which are identified over time. As needed, the resource monitoring program and technical reports will be coordinated with interested regulatory agencies such as the Regional Water Quality Control Board, the California Department of Health Services and the California Department of Toxics and Substance Control.

**ATTACHMENT TO MEMORANDUM OF UNDERSTANDING
BETWEEN
UPPER BASIN WATER PURVEYORS AND UWCD**

NEWHALL COUNTY WATER DISTRICT strongly supports a cooperative working relationship and establishment of a joint monitoring program among the signatories of the attached Memorandum of Understanding (MOU).

This attachment shall not be construed to alter either the terms of agreement or the proposed activities that are the substance of the MOU. Rather, the intent is to describe the District's interpretation of the document and to convey their resulting expectations to the parties to the MOU.

- Subcommittee membership, meeting times, and locations will be finalized within six months. Subcommittee structure and organization will be documented and incorporated into the MOU by reference. Opportunities for public participation will be defined and included in the process.
- Cost estimates, activity plans and schedules, engineering data, models and modeling results, actual expenditures, and reports generated will be considered public information and made available under the terms and conditions of current law and established policies.
- Neutral technical expertise to ensure objective analyses and recommendations will be provided through inclusion of a USGS "expert" as a working member of the Technical Committee. Conclusions, proposals, and extrapolation of data must proceed from a credible foundation.
- As the provisions of the MOU are fulfilled, the parties will undertake regional water planning efforts to protect and enhance the water resources within the region. Water Code Sections 10750 through 10795 describe activities that may be included, where feasible.
- The Upper Basin Water Purveyors recognize the importance of the alluvial aquifer as a source of water supply for the residents of the Santa Clarita Valley, and will cooperatively encourage replenishment projects, particularly in the eastern reaches of the Santa Clara River.

Attorneys for Petitioners

FILED
KERN COUNTY
AUG - 3 2000
TERRY McNALLY, CLERK
BY__________ DEPUTY

SUPERIOR COURT OF CALIFORNIA, COUNTY OF KERN

UNITED WATER CONSERVATION DISTRICT, Petitioner, vs. COUNTY OF LOS ANGELES, et al., Respondents, __________ THE NEWHALL LAND AND FARMING COMPANY, et al., Real Parties in Interest, __________ AND RELATED CASES. __________	Kern Case No. 239324-RDR (Consolidated w/ 239325, 239326 and 239327-RDR) [~~PETITIONERS' PROPOSED~~] **STATEMENT OF DECISION** Date: March 2 and 3, 2000 Time: 8:30 a.m. Dept.: 6 Judge: Roger D. Randall

The above-entitled consolidated actions were heard on March 2 and 3, 2000, by the Honorable Roger D. Randall in Department 6 of the Kern County Superior Court. Petitioners County of Ventura, Ventura County Flood Control District, Ventura County Air Pollution Control District, the City of Oxnard, City of San Buenaventura, City of Santa Paula, Fox Canyon Groundwater Management Agency and United Water Conservation District ("the Ventura County petitioners") appeared by and through their counsel, Dennis L. Slivinski and Antonette Benita Cordero, Assistant County Counsel for the County of Ventura. Petitioners and plaintiffs Sierra Club, Friends of the Santa Clara River and Santa Clarita Organization for Planning the Environment ("the Sierra Club petitioners") appeared by and through their counsel John T. Buse of the Environmental Defense Center, and Jan Chatten-Brown and Douglas P. Carstens of Chatten-Brown and Associates. Petitioners and plaintiffs Maria Vega, LaVerne Drew, Luis Serrano and Silvestre Silva ("the Vega petitioners") appeared by and through their counsel, David Pallack of the San Fernando Valley Neighborhood Legal Services, and Michael Rawson of the California Affordable Housing Law Project. Respondents and defendants, County of Los Angeles and the Board of Supervisors of the County of Los Angeles ("Respondents"), appeared by and through their counsel, Peter J. Gutierrez, Senior Deputy County Counsel for the County of Los Angeles, and Charles J. Moore of Cox, Castle & Nicholson. Real parties in interest, The Newhall Land and Farming Company, Valencia Corporation, The Newhall Ranch Company, and Newhall Management Limited Partnership (collectively, "Newhall") appeared by and through their counsel, Mark J. Dillon and Thomas Deak of Gatzke, Dillon & Ballance. Amicus Curiae the People of the State of California appeared by and through their counsel, Brian Hembacher and Sarah E. Morrison, Deputy Attorneys General for the State of California, in support of petitioners and plaintiffs. Amicus Curiae the Castaic Lake Water Agency ("CLWA") submitted a brief in support of the Respondents, but did not appear at the hearing.

The Court has accepted into evidence the Newhall Ranch Administrative Record, consisting of Volumes 1 through 67 (Bates pages 000001 through 063177), a separate Index Volume, a graphics binder (Volume 68) as well as oversized graphics (Bates pages 200003 through 200131), and Supplemental Administrative Record Volumes 1 through 4 (Bates pages 001 through 2503).

In these consolidated actions, the petitioners and plaintiffs challenge Respondents' approval of the Newhall Ranch Project, which would include up to 22,038 dwelling units and a 6.9 million gallons per day water reclamation plant. Specifically, the Project includes General Plan Amendment 94-087-(5), Santa Clarita Areawide Plan Amendment 94-087-(5), the Newhall Ranch Specific Plan, Zone Change 94-087-(5), Conditional Use Permit 94-087-(5), and Vesting Tentative Parcel Map No. 24500-(5).

Petitioners' challenges are brought under the California Environmental Quality Act ("CEQA")[1], the Subdivision Map Act[2] and the Planning and Zoning Law.[3]

The Court has received, read, and considered the memoranda of points and authorities submitted by the various parties to the above-entitled consolidated actions and the two amicus briefs, as well as the oral arguments of all counsel. It has also received and, to the extent appropriate, reviewed the Administrative Record in this case. Being thus informed concerning the issues, the Court has arrived at the conclusions set forth in this Statement of Decision.[4] We begin with a discussion of the Subdivision Map Act which concerns a non-CEQA issue.

THE SUBDIVISION MAP ACT ISSUE

In 1851 the State Legislature created the County of Los Angeles and established its boundaries. At that time the three lots that are impacted by the subdivision in question in the instant case already existed, and were bisected by the western-most county line of Los Angeles County. Thereafter, in 1872, Ventura County was created, and from that point forward has shared the bisecting county line with Los Angeles County. Consequently, the westerly portions of the three lots impacted by the subdivision are located in the eastern portion of Ventura County.

It is the view of Ventura County that the effect of the approval by the Los Angeles County Board of Supervisors of the Vesting Tentative Parcel Map was to cause the three original lots to be subdivided into 33 smaller lots, 30 of which are in Los Angeles County (those on which the Project is scheduled to take place) and three of which are in Ventura County. Ventura County argues that the Los Angeles Board of Supervisors' action "... severed the portions of the lots in Ventura County from the portions in Los Angeles

---

[2] Government Code sections 66410 et seq.

[3] Government Code sections 65000 et seq.

[4] Where in the course of the ruling several parties have argued the same point, the ruling does not always acknowledge all the arguments advanced on that point. However, the ruling is informed by all of the arguments which were advanced concerning a given issue being urged by counsel.

County, creating three new lots entirely within Ventura County." Since the purpose of the subdivision was the sale, lease or financing of the lots, then it is Ventura County's view that the lots they style as the three new lots within Ventura County are part and parcel of the subdivision and, consequently, should have triggered a joint application to the Boards of Supervisors of both Ventura and Los Angeles Counties for subdivision approval.

Both Los Angeles County and Ventura County agree that neither county may approve a subdivision beyond its borders; however, Respondents contend that there was no subdivision in Ventura County because the three original lots were divided more than 100 years ago when the border between Los Angeles County and Ventura County was established; and also, should that not be so, the portions of the three original lots that are in Ventura County are either remainders or excluded portions of the property, not subject to the Subdivision Map Act.

A. **The Standard of Review**

Having agreed to disagree, Los Angeles and Ventura cannot agree on the standard of review to be utilized by this Court in examining the issue before it. Ventura contends that, since this Court is dealing with an issue of statutory interpretation, the Court must use its independent judgment in this case of first impression in determining whether Respondents violated the law by approving the tentative map without requiring a joint application by Newhall Ranch to the County of Ventura. Ventura County relies on *City of Lafayette v. East Bay Mun. Utility Dist.* (1993) 16 Cal.App.4th 1005, 1013, for this proposition.

Respondents contend that the standard to be utilized is the substantial evidence test in determining whether Los Angeles County's approval of VTPM 24500 complies fully with the Subdivision Map Act. They rely on the case of *Pescosolido v. Smith* (1983) 142 Cal.App.3d 964, 967. We shall conclude that Ventura is correct and that the standard of review with regard to the Subdivision Map Act question is that of an independent review and the exercise of the independent judgment of the trial judge.

In the *Pescosolido* case, the trial judge concluded:

> (3) Petitioners' right to dispose of their property is a fundamental right protected by state and federal constitutional provisions; accordingly, this Court must apply the independent judgment test in reviewing the record of the proceedings before the administrative bodies involved.

(*Pescosolido v. Smith, supra,* 142 Cal.App.3d at p. 967.)

The court had before it a case in which the senior Pescosolidos wished to divide their property between several children and to retain a single parcel for themselves. The parents owned a 37.60-acre lot and wanted to give the parcels to the children, not with the intent that the parcels be sold, but to allow the children to use the land they received to help finance their college educations. The Tulare County Planning Department denied the Pescosolidos' application for certificates of compliance as to the six portions of land they had deeded to their children and ultimately their applications for certificates of compliance were denied with the finding that the lots created by the six deeds to the children were in violation of Tulare County Ordinances governing the subdivision of land.

On the record before it, the Court of Appeal concluded:

> [W]e are not dealing with an absolute prohibition against the right to alienate property or the right to make *inter vivos* or testamentary gifts to one's children which very well could involve a fundamental and vested right. It is more accurate to ask whether a county's refusal to permit owners of land to divide it into discrete parcels without seeking local governmental approval substantially affects or involves the right to make gifts of that land.

(*Pescosolido v. Smith, supra,* 142 Cal.App.3d at p. 969.)

The court thus concluded:

> The elder Pescosolidos' desire to provide their children with a gift of maximum monetary value was certainly an understandable and admirable expression of familial devotion, but the specific objective of maximization of market worth does not outweigh the interest of the public in land development regulation and is not important enough to require full and independent review by the courts. It was therefore error for the trial court to apply its independent judgment and reweigh and evaluate the evidence before the Board.

(*Pescosolido v. Smith, supra,* 142 Cal.App.3d at p. 970.)

///

The appellate court did not cite to authority for its conclusion that the independent judgment test should not apply in a case where the issue before the court did not raise a fundamental question of statutory or constitutional right. However, utilizing that analysis, we now turn to the question before this Court.

Both Ventura and Los Angeles cite to numerous authorities emphasizing the significance of the Subdivision Map Act and the importance of complying with its terms. We do not here deal with a question of the manner in which a private property owner undertakes to convey portions of their real estate, but rather we deal with a fundamental question of the power of one political subdivision to impact the operation of another co-equal political subdivision. Under these circumstances, the utilization of the independent judgment test constitutes the appropriate standard.

B. Analysis of the Problem

The Los Angeles County Board of Supervisors adopted a finding that:

> [B]ased on a review of the vesting tentative parcel map, as well as substantial evidence in both the Final EIR and the administrative record, the applicant's vesting tentative parcel map does not include any land situated within Ventura County and, on that basis, Ventura County has no jurisdiction over the parcel map under the Subdivision Map Act because no "subdivision" of land is proposed in Ventura County. . . . In addition, the Board finds that, based on substantial evidence in the record, the vesting tentative parcel map is consistent with the State Subdivision Map Act . . . .

(A.R. 6435-6436, ¶ 25.)

In support of the finding of the Los Angeles County Board of Supervisors, Respondents argue:

> In forming the two counties and describing each as a "legal subdivision of the state," the Legislature divided the so-called "transcounty" lots along the counties' common boundary line as a matter of law.

They cite no authority for this proposition. On the other hand, petitioner relies upon an opinion of the Attorney General (61 Ops.Cal.Atty.Gen. 299, 301, (1978)) addressing an analogous situation to that which we find currently, and the Court finds the reasoning of that opinion persuasive.

In the referenced opinion the Attorney General concluded that commonly owned units of land could be developed as a single subdivision project even though separated by a fee simple strip of land owned by another (in that case a federal governmental unit) and concluded, therefore, that the units could be considered contiguous under Government Code section 66424. That code section provides, inter alia, that property shall be considered as contiguous units, even if it is separated by roads, streets, utility easements or railroad rights of way. Consequently, we conclude that the portions of the three lots in question that are situated in Ventura County have not been severed by law from the portions of the lots situated in Los Angeles County.

The question then remains whether the portions of the three lots that are in Ventura County must be included within the subdivision. If so, Ventura County must be included in the process of adopting the map.

Respondents argue that even if VTPM 24500 divides property situated partially in Ventura County, nevertheless the Map Act authorizes Newhall to entirely omit that portion of the property that lies in that County because Government Code section 66424.6, subdivision (a), provides that:

> When a subdivision, as defined in Section 66424, is of a portion of any unit or units of improved or unimproved land, the subdivider . . . may omit entirely that portion of any unit of improved or unimproved land which is not divided for the purpose of sale, lease, or financing.

Petitioner points out that the Vesting Tentative Parcel Map did not designate any remainders. Consequently, no remainder could have been created pursuant to the provisions of Government Code section 66424.6, subdivision (a). However, a reading of the statute appears to indicate that, while certain activity must be undertaken to designate a remainder, it is possible to omit a portion of a parcel of land that is not scheduled for development while creating a subdivision on another portion of the land, and this, Respondents argue, is what has been done here. Nevertheless, petitioner asserts that parties cannot subdivide a portion of their property, then omit or treat as a remainder the rest of that property if their intent is to sell, lease, or finance the so-called remainder.

Ventura County relies on an Attorney General's opinion found at 77 Ops.Cal.Atty.Gen. 185 (1994), which concluded that under the provisions of the Subdivision Map Act a remainder cannot be designated when a developer subdivides portions of the parcel for the first phase of a housing development while intending later to subdivide the undeveloped portions for subsequent phases of development.

Respondents contend that the record demonstrates Newhall Ranch has no intention to shift from agricultural pursuits on the Ventura property and to develop the land in Ventura County. Ventura County, however, is able to demonstrate that Newhall Ranch has clearly shown its intent to develop all of its land, including the land in Ventura County, in the future. For example, the Ventura County land has been allowed to lapse from Williamson Act protection (Gov. Code, § 51200 et seq.); and the Administrative Record is replete with statements by Newhall Ranch that it is now in the business of real estate development. Given that this is so, argues Ventura County, there can be no omitted portion of the property in question when it is intended that all of the property will ultimately be developed. In this regard, Ventura County is wrong.

In *Pescosolido v. Smith, supra,* 142 Cal.App.3d, the appellate court concluded:

> [T]he grants to the children of specific parcels were not invalid so long as they used the property for agricultural purposes. The restriction imposed was a prohibition against division in distinct parcels for the purpose of present or future sale or development. The prohibition is against transfer in discrete units for subdivision development without complying with the Subdivision Map Act.

(*Id.* at p. 969.)

While it is no doubt accurate to say that Newhall Ranch is presently in the primary business of creating "value from land by meeting the needs of a growing population" (A.R. 13631), the record does not demonstrate that the portion of the three lots situated in Ventura County is being severed from the 30 subdivided lots in Los Angeles County for the purpose of sale, lease, or financing. The record demonstrates that the property in Ventura County is still being used for agricultural purposes and is devoid of any indication that that property is being omitted for the purpose of allowing a second, third, or fourth phase of development of the Project now in planning in the future. Consequently, there was no need for Newhall Ranch to apply to Ventura County for subdivision map approval.

IS THE SPECIFIC PLAN CONSISTENT WITH THE FUNDAMENTAL POLICIES OF THE LOS ANGELES COUNTY GENERAL PLAN (HOUSING)?

The Vega petitioners contend the Newhall Ranch Project is void because the Specific Plan is inconsistent with the fundamental policies of the Los Angeles County General Plan. They assert that the Specific Plan is inconsistent with certain of the county's housing element goals and also with general policies found in the background report of the General Plan.

Petitioners point out that of the various elements of a General Plan required by the Government Code, the housing element is of "preeminent importance." (*Committee for Responsible Planning v. City of Indian Wells* (1989) 209 Cal.App.3d 1005, 1013). They also point out that the Southern California Association of Governments ("SCAG") has determined Los Angeles County's share of future regional needs for housing. That determination was incorporated in the County's assessment of housing needs in its housing element, reflecting a total need for 34,039 units comprising very low income, low income, moderate income, and high income (to say nothing of a need for 54,613 very low income and low income households to achieve affordable housing because they are currently overpaying for housing). To meet those needs, the housing element established as its first goal:

> [A] sufficient quantity of dwelling units to meet the housing needs of the population, particularly those lower-income households and other special needs groups such as elderly and the homeless.

Petitioners contend that the Specific Plan will create a greater need for low-cost housing than the plan will accommodate and that the Specific Plan's consistency analysis regarding Goal One ignores that shortfall.

Respondents argue that the Los Angeles County General Plan is not intended to mandate a precise quid pro quo of housing units to jobs or housing units to population in a given development. The introduction to the General Plan contains the following language:

> The *General Plan* provides general policy direction for the future of the County; it is not a detailed blueprint for action. . . The Plan is the tool to guide decision-making related to overall land use direction and development in the County . . . At the time specific decisions are made . . . the appropriate decision-making authority must interpret and weigh various Plan policies based on the best information available at the time. Thus, the *General Plan* neither promises nor guarantees the achievement of a particular goal nor strict adherence to any single policy statement.

(A.R. 7121.)

Petitioners also allege that Goal Three of the housing element has not been met: "A housing supply that ranges broadly enough in price and rent to enable <u>all</u> households, regardless of income, to secure adequate, affordable housing." They argue that the plan is inconsistent with the goal because, while it creates affordable housing, the need based upon jobs and the like created in the area is greater than the need accommodated. Respondents reply that their plan supplies 2,200 dwelling units qualifying as very low, low, or moderate income housing, and reiterate that they are not required by any policy or plan to supply 100 percent of the affordable housing needs existing in an approved project area.

The Vega petitioners also raise the question whether Goal Four has been adequately met:

> Adequate housing, accessible to employment and community services for all persons, regardless of race, ethnic background, sex, age, marital status, <u>income</u>, or disability.

Petitioners contend that the plan is inconsistent with that goal:

> [B]ecause the plan fails to provide sufficient housing to meet the additional need for housing affordable to very low and low income households generated by the low wage employment opportunities that will be created.

///

///

The Court is satisfied that substantial evidence supports the finding of the Respondent Board of Supervisors that the Specific Plan was consistent with the housing elements of the General Plan:

> Once a general plan is in place, it is the province of elected city officials to examine the specifics of a proposed project to determine whether it would be "in harmony" with the policies stated in the plan. [Citation.] It is, emphatically, *not* the role of the courts to micromanage these development decisions. Our function is simply to decide whether the city officials considered the applicable policies and the extent to which the proposed project conforms with those policies, whether the city officials made appropriate findings on this issue, and whether those findings are supported by substantial evidence. [Citations.]

(*Sequoyah Hills Homeowners Assn. v. City of Oakland* (1993) 23 Cal.App.4th 704, 719.)

The Vega petitioners further allege that the Newhall Ranch approvals should be enjoined because the Respondents failed to update the housing element of the General Plan to address the substantial additional need for affordable housing the Project would create. They pointed out that the law requires revision of the General Plan as frequently "as appropriate, but not less than every five years . . . ." (Gov. Code, § 65588, subd. (b).) While conceding that the statute does not define "as appropriate," petitioners argue that the Project in question is of such a magnitude that its implementation must necessarily trigger such a review. In the instant case, the Court does not find a basis for concluding that it was an abuse of discretion for the Board of Supervisors of Los Angeles County to conclude no revision was required by the implementation of this Project.

Petitioners contend that the EIR improperly concludes that the Specific Plan will have no significant impact on regional or local population, housing and employment. They argue that the EIR reaches its conclusion by relying on the consistency of the increases in population, housing and employment projected by the Project with the SCAG Planning Forecast. In this regard the EIR has four flaws, the first being that there is no evidence in the record to support the conclusion that consistency with planning forecasts means that the Project will have no significant impact on the environment. They base this argument on the theory that if an EIR was prepared at the time of the development of the SCAG forecast, and if that EIR is being relied upon, it must be set forth and analyzed in the development of the current EIR. Respondents, however, argue correctly that they are relying upon the SCAG projections themselves and not upon the underlying EIR. Both sides cite to CEQA Guidelines section 15150, and related Guidelines. It is apparent that the manner in which the SCAG forecast was utilized in the current EIR is consistent with those Guidelines.

The Vega petitioners next argue that the EIR used the wrong legal standard to evaluate Project impacts. In the EIR, Respondents state that:

> According to Appendix G of the State CEQA Guidelines, as amended, a project is considered to have a significant effect on the environment if it will induce substantial growth or concentration of population, and cumulatively exceed official regional or local population forecasts.

(A.R. 5036.) Petitioners correctly point out that Respondents have mischaracterized Appendix G in that the appendix lists a number of items that will normally have a significant effect on the environment, one of which is "conflict with adopted environmental plans and goals of the community where it is located . . . ." That listing is not conjunctive, but rather is disjunctive with other items on the list. Consequently, petitioners conclude that Respondents have simply relied upon their misreading of Appendix G to allow them to conclude there are no significant or environmental effects based upon the increased population, housing and employment to be generated by the Project in question.

Respondents conceded the error in their reply to Ventura County's comment during the comment period but now argue that CEQA does not require the precise application of the Appendix G significant thresholds but rather allows agencies to format their own versions. They point out that in the case of the County of Los Angeles, the County has adopted an environmental checklist tailored to the needs of Los Angeles County, which tailoring is authorized by CEQA Guidelines section 15063, subdivision (f). Respondents also argue that their analysis of the utilization of various adopted environmental plans and goals demonstrates proper compliance with CEQA. The Court concurs.

Petitioners argue that the EIR fails to analyze the impact of its excessive employment projections, pointing out that Respondents admit their employment projections exceed SCAG's estimate but argue that the increase will not be significant because upon completion of the Project the jobs/housing ratio in the Santa Clarita Valley will be the same as SCAG's target ratio. Petitioners assert that statement, however, does not take into account the fact that there will be many years when the jobs and housing ratio in the interim is not balanced and also does not consider the cost of housing in relation to available jobs. They cite to no authority for the proposition that the EIR must analyze a jobs/-housing imbalance in order to comply with CEQA. Absent such a requirement in the form of a statute or guideline, this Court cannot impose such a requirement upon the proponent of an EIR.

The Vega petitioners contend that Respondents were presented with a fair argument that a lack of affordable housing would impact the environment by causing undue commuting and traffic congestion as low-income employees attempted to reach jobs in the Project. The Respondent Board of Supervisors concluded there were affordable housing opportunities within the suburbs for low-wage jobs being created there:

> Los Angeles County believes that the Newhall Ranch Specific Plan provides both the wage and housing mix necessary to discourage low-wage workers from commuting. As discussed in **Topical Response 10** - Provision of Affordable Housing on the Specific Plan Site, lower-wage earners in the average or higher wage categories would be able to afford estimated rents within Newhall Ranch without sharing a unit. Persons earning the lowest wage reported would also be able to afford a Newhall Ranch rental unit if they shared the unit with another person. Some people with the lowest, or no wages, could be accommodated in Second Units, or granny flats.
>
> In addition, higher density multi-family units are located close to commercial and employment centers and transportation routes. This design reduces the potential for a "commuting class of low-wage earners."

(A.R. 16927.)

After examining the record created with regard to analysis of the availability of affordable housing within the Project, this Court (while it might question the

/ / /

practicality of the granny flat solution) cannot conclude that there is no substantial evidence supporting the finding just quoted.

The Vega petitioners also argue that the EIR fails to identify all significant effects of the increase in population, employment and housing. Respondents point to the analysis found at Administrative Record pages 5025 through 5058 which deals with the increases in population, housing and employment anticipated as a result of approval of the Specific Plan. Substantial evidence contained within the Administrative Record justified the conclusion of the Board of Supervisors that the Specific Plan adequately analyzed transportation, population and employment impacts. While petitioners point to the alleged paucity of Respondents' solutions for the affordable housing/employment/population increase aspect of the plan, they ignore the fact that the plan does introduce a substantial number of low-income housing units into the mix. As Respondents repeatedly assert, the EIR need not purport to solve all of the housing problems facing Los Angeles County, but rather must analyze the effect of the Project itself on the portion of the County which will be directly impacted by the planned Project.

DOES THE EIR ADEQUATELY ANALYZE AND MITIGATE THE SPECIFIC PLAN'S BIOLOGICAL IMPACTS?

Sierra Club petitioners allege that the EIR improperly defers the analysis and mitigation of the Project's biological impacts. They point out that the EIR concludes the Specific Plan would "substantially diminish habitat for wildlife and plants" and "significantly impact sensitive wildlife species, significantly impact the ability of animals to move across portions of the site, and significantly impact several sensitive upland habitat types." That being the case, they argue that the EIR lacks specificity in its treatment of biological resources and, in essence, defers evaluation of the impact of the Project on fish

///

///

///

and wildlife until the approval process for Specific Tract Maps, or for section 404[5] permits and section 1603[6] agreements. This deferral:

> [C]onfounds any good faith effort to understand the Project's impacts on wildlife and plants. In general, the Project's potential impacts on number of rare and endangered species are discussed without any connection to where these impacts will occur, when during the Project's 30-year buildup they will occur, and how the anticipated destruction of habitat actually affects the species. Where potentially significant impacts are identified, the reader is directed to a set of boiler plate mitigation measures that bear no clear relation to the particular impacts that they are supposed to address.

As an example of this treatment, petitioners review the EIR's approach to Project impacts on the least Bell's vireo, a state and federally listed endangered songbird. The EIR references mitigation measures 4.6-1 through 4.6-26, 4.6-53, 4.6-56, and 4.6-59, which are designed to reduce the Project's impacts to the vireo to a less than significant level. The Sierra Club petitioners allege that analysis of those measures "describe an extremely general habitat restoration, enhancement, and management program," and otherwise does not demonstrate that the mitigation measures will address the impact on the vireo. A similar analysis can be utilized for most of the additional endangered or threatened biological species identified in the EIR and, therefore, the EIR does not pass muster with regard to its discussion of the impacts on the biological resources in the Project area. "In general, an agency may not defer the formulation of mitigation measures to some future date pending the additional assessment of environmental impacts. Sundstrom v. County of Mendocino (1988) 202 Cal.App.3d 296, 306-307 . . . . The mitigation framework defers not only the small details of 'environmental problem-solving', but also the establishment of the standards and criteria needed to evaluate the adequacy of mitigation."

---

[5] Section 404 of the Federal Clean Water Act (33 U.S.C., § 1344 et seq.).

[6] Section 1603 of the California Fish and Game Code.

Respondents contend that:

> [C]ontrary to the impression painted by petitioners, the EIR contains a 155 page analysis of the biological setting of the Specific Plan site, the Project-Specific and cumulative impact of the Specific Plan and the biological mitigation program adopted by the County. . . . As part of the environmental review process, the County prepared 11 technical studies and documents devoted solely to the biological impacts of the Specific Plan, including a detailed biological impact report . . . . In addition, the Specific Plan itself contains a 'Resource Management Plan,' which provides regulations and standards by which biological resources within the Specific Plan area will be managed. . . . In approving this Specific Plan, the County also adopted a Mitigation Monitoring Plan, which includes no less than 98 enforceable measures for the mitigation of the Specific Plan's biological impacts . . . .

The Court has reviewed the Resource Management Plan and the Mitigation Monitoring Plan referenced by Respondents. It agrees with amicus counsel from the Attorney General's Office that mitigation measures that require compliance with environmental regulations are proper only where the public agency had "meaningful information" that justified an expectation of compliance, and also that the CEQA Guidelines in essence allow such mitigation measures so long as they "may specify performance standards which would mitigate the significant effect of the project and which may be accomplished in more than one specified way." (14 Cal. Code Regs., tit. 14, § 15126.4, subd. (a)(1)(B).) It does not agree, however, with the argument of the Sierra Club or amicus counsel that the mitigation measures being challenged herein do not include performance standards which would mitigate impacts on sensitive species and sensitive habitat. The mitigation requirements discussed in the Administrative Record at pages 4453-4471 do include performance standards that can be utilized to hold the Respondents to compliance with the EIR, and that adequately inform the public of the nature of the proposed mitigation designed to reduce the significant impacts on biological resources in the area during the development of the Project.

Sierra Club petitioners have analogized the situation regarding biological impacts analysis in this case to the Project addressed by the Court of Appeal in *Stanislaus Natur Heritage Project v. County of Stanislaus* (1996) 48 Cal.App.4th 182. There a project of substantial magnitude was contemplated and the County of Stanislaus certified an EIR for a proposed specific plan submitted by the developer involving the creation of an approximately 30,000-acre destination resort and residential community. The project was to be developed in phases over 25 years, and water had only been secured for a portion of the first phase (five years out of the fifteen years contemplated for that phase).

> The County knew neither the source of the water the project would use beyond the first five years, nor what significant environmental effects might be expected when the as yet unknown water source (or sources) is ultimately used.

(*Id.* at p. 195.) The respondent developer and county in the *Stanislaus* case contended that they planned to undertake a site-specific environmental review for each of the four phases of development and that they could properly defer analysis of the environmental impacts of supplying water to the project until they had selected the source of supply in the future. The court said:

> "[T]iering" is not a device for deferring the identification of significant environmental impacts that the adoption of a specific plan can be expected to cause. The County in this case could not make an informed decision on whether to adopt the Diablo Grande Specific Plan without being informed, to some reasonable degree, of the environmental consequences of supplying water to a 5,000-residential-unit development which has no on-site water source.

(*Id.* at p. 199.)

It was this total lack of information that caused the *Stanislaus* court to reject the EIR there being proffered. In contrast, the environmental consequences of the Project to biological resources on site have been explored in the instant case and mitigation measures adopted with performance standards specific enough to demonstrate the feasibility of the mitigation that is proposed.

The Sierra Club petitioners allege that the EIR does not include an adequate discussion of the Project's impacts on tributary streams, pointing out that of approximately 92,500 linear feet of blue line drainage courses affected by Project activity, approximately 52 percent of the stream area in question would be converted to closed drainages. The Sierra Club petitioners allege that, in essence, there was an inadequate response to remarks of the U.S. Fish and Wildlife Service ("USFWS") comment that the EIR "grossly undervalued" the Specific Plan areas existing on ephemeral drainages.

Respondents disagree as to the significance of that comment, arguing that the USFWS's comment had to do with criticism of the EIR's analysis of the use of the ephemeral drainages as wildlife corridors, rather than a criticism of the analysis of the drainages as such. Respondents allege that they did respond to the USFWS's comment when the comment is put in proper context. They also argue that the petitioners' argument on this ground must fail:

> [B]ecause it presents no tangible issue (i.e., it never contends that the Specific Plan will cause an adverse significant impact on minor streams). Petitioners summarize the Specific Plan's method of altering on-site drainage courses, but never explain how this methodology will cause a significant environmental impact.

In the absence of any indication on the record that the Specific Plan will cause an adverse significant impact on minor streams, the Court finds no basis for granting the relief sought by petitioners based upon this ground.

The Sierra Club next contends that the EIR does not adequately address impacts of biological resources related to flood plan modifications. They point out that, although several individuals and agencies have commented upon the effect of modifications to the river and channels insofar as biological resources were concerned, the only effort to address these concerns was with reference to the County Public Works Department's Sedimentation Manual, and then argument from inference that the minimal change in velocity caused by channelization would not affect aquatic resources.

Respondents argue that if there is no anticipated significant sedimentation or scouring impacts on the Santa Clara River from channelization or hardening of its banks for insertion of the fill in the flood plain "implementation of the Specific Plan is not expected to affect fish movement anywhere along the river." Unfortunately, this reliance upon the quoted language in the EIR does not address the issue posed. The California Department of Fish and Game commented on impacts to the unarmored three-spine stickleback based upon narrowing of the river channel and increased flow velocities, and there was further comment regarding impact of channelization and restriction of the river bottom on river habitat and dependent species (A.R. 14826). Conversely, there is no substantial evidence to justify the conclusions reached by Respondents that there would be no adverse biological impacts on the river corridor based upon channelization and hardening of the banks. The fact that a lack of significant sedimentation or scouring would equate to an environment which did not affect fish movement along the river begs the question. Consequently, petitioners are entitled to relief with regard to this issue.[7]

IS THE EIR'S ANALYSIS OF THE WATER RECLAMATION PLANT'S IMPACT ON BIOLOGICAL RESOURCES INADEQUATE?

In his amicus brief the Attorney General argues that the Water Reclamation Plant ("WRP") as cited in the plan will have significant biological impacts that are not addressed other than in a cursory fashion in the EIR. He also argues that there was an inadequate analysis of alternatives to the WRP.

An analysis of the minimal discussion of the siting of the Water Reclamation Plant in the Specific Plan at the river location demonstrates that there was substantial evidence to justify rejection of the "no WRP" alternative and the alternatives involving siting of the plant upstream of the Project or downstream of the Project, or expansion of the existing WRP in the area. However, the Court concurs with the Attorney General that there is no substantial evidence to justify the finding that siting of the WRP at a non-river location will not mitigate the biological impacts concededly caused by the siting of the plant as proposed immediately adjacent to SEA 23 (Significant Ecological Area), and impacting some acreage, although small, of sensitive habitat (about 10 acres) (A.R. 51011).

---

[7] The Sierra Club has argued that the EIR does not adequately address impacts to biological resources that are related to Project-induced changes in groundwater levels. Because that argument deals with the effect of storage of the Castaic Creek flood waters via the ASR alternative, and because of the conclusions the Court reaches in its findings on the water issues, there is no discussion of this issue in this portion of the ruling.

Given the fact that no substantial evidence justifies rejection of the mitigation of the alternative of a non-river site, and the minimal discussion of the biological impacts of siting the WRP on the river, the EIR is deficient in its analysis of the Specific Plan location of the WRP.

DOES THE EIR ADEQUATELY ANALYZE THE ALTERNATIVES AVAILABLE TO THE PROJECT?

Sierra Club petitioners allege that there is no substantial evidence supporting the Respondents' rejection of feasible alternatives to the Specific Plan. It then discusses the six alternatives that were presented in the planning documents and, using Alternative Five as an example, argues the inadequacy of the analysis provided. Specifically, it argues that the conclusion that Alternative Five would impede the ability of the developer to earn a reasonable return on his investment "requires specific evidence that cost or profit considerations make an environmentally superior alternative truly impractical." Respondents argue that there was substantial consideration of the alternatives documented in the record with adequate information contained therein to allow an intelligent analysis of the alternatives. The Court has reviewed the Administrative Record with regard to the discussion of the six alternatives and has concluded that the argument that no substantial evidence supports Respondents' rejection of feasible alternatives must be rejected, notwithstanding the failure of the Respondent to adequately document the economic aspect of the implementation of Alternative Five. CEQA Guidelines section 15126.6, subdivision (d), provides:

> The EIR shall include sufficient information about each alternative to allow meaningful evaluation, analysis, and comparison with the proposed project. A matrix displaying the major characteristics and significant environmental effects of each alternative may be used to summarize the comparison. If an alternative would cause one or more significant effects in addition to those that would be caused by the project as proposed, the significant effects of the alternative shall be discussed, but in less detail than the significant effects of the project as proposed.

Whereas in *Citizens of Goleta Valley v. Board of Supervisors* (1988) 197 Cal.App.3d 1167, 1181, the proponent of the project had given an inadequate economic analysis as to the feasibility of the scaled down project, and had made no other meaningful analysis of negative aspects of the alternative other than those economic reasons, in the instant case a variety of matters were considered and adequately documented to justify the finding that the six alternatives propounded were infeasible.

IS THE SPECIFIC PLAN CONSISTENT WITH THE FUNDAMENTAL POLICIES OF THE LOS ANGELES COUNTY GENERAL PLAN (NATURAL RESOURCES)?

Sierra Club petitioners argue that the Newhall Ranch Project is inconsistent with General Plan policies requiring protection of natural resources, especially Significant Ecological Areas ("SEAs"). They point out that:

> In the Land Use Element of its General Plan, Los Angeles County has designated certain areas as special management areas . . . due to the presence of natural and scenic resources or hazards. Significant Ecological Areas, which are ecologically important or fragile land and water areas that are valuable as plant and animal communities, are one type of SMA.

It then argues that, given the intent of the General Plan policy which was designed to preserve the County significant ecological resources in natural condition, the Project in question would adversely affect SEA 23 by authorizing extensive commercial and residential development, as well as three bridges within the confines of that area.

Petitioners contend that, although the Board amended the General Plan to change the boundaries of SEA 23, the action of amending the plan in this regard was contrary to several General Plan policies designed to conserve natural habitats. It points out that more than 103 acres of the most sensitive habitat types are being eliminated from SEA 23 and argues that, although the General Plan Amendment states that the modification of the boundaries of SEA 23 are done to "in part, better reflect the sensitive biological resources present on the site," it is clear that the real rationale for the amendment of the boundary was "made to accommodate the siting of commercial and residential uses rather than merely to reflect the presence of biological resources."

/ / /

Respondents contend that sufficient findings were made by the Board to justify the modification of SEA 23, and point out that the addition of acreage with a Special Management Area ("SMA") designation immediately adjacent to the SEA 23 area will result in an increase of approximately 155 acres of protected habitat. Petitioners, however, point out that:

> Here, the Board improperly reduced the size of SEA 23, then created the River Corridor SMA to include portions of SEA 23, and then made findings about the SMA which were not based upon substantial evidence. By doing so, the Board failed to make findings about SEA 23, as it is required to do.

Respondents argue that on a percentage analysis "only 22% of the impacted area of SEA 23 consists of sensitive habitat," and argue that, in essence, better habitat is being substituted in the SMA for poorer quality habitat being deleted in SEA 23 (other than the 103 acres previously referenced). Respondents also argue that any impacts to SEA 23's sensitive habitat are mitigated according to the Specific Plan:

> All of the riparian vegetation and all *oak resources* will be restored in the most suitable areas of the *SMA* as identified and required under the Resource Management Plan or under regulations of the ACOE [Army Corps of Engineers] and State Department of Fish and Game.

This argument, however, begs the question because the fact that all riparian vegetation and all oak resources will be restored somewhere in the SMA does not address the fact that 103 acres of highly sensitive habitat are being deleted from the SMA. Because the Board chose to address its findings within the context of the River Corridor SMA, this Court cannot conclude on the record that substantial evidence supported the findings made by the Board with regard to deletion of highly sensitive habitat from SEA 23.

The Court cannot discern from the record that there is substantial evidence to justify the finding of the Board which was designed to satisfy General Plan Policy 2.22 and the County Zoning Ordinance requirement that in granting a CUP the roads and utilities serving the development be located and designed "so as not to conflict with critical resources, habitat areas, or migratory paths," given the fact that in other portions of the CEQA findings we have the following language:

> Wildlife movement along the Santa Clara River through the Specific Plan area will also be affected by adjacent development and several bridges across the River.

(A.R. 6631.) Consequently, the Court agrees with the Sierra Club's argument that the Newhall Ranch Project is inconsistent with General Plan policies requiring protection of natural resources insofar as SEA 23 is concerned.

Insofar as the Sierra Club petitioners have advanced other arguments concerning the treatment of SEA 23 the Court has reviewed the record and concluded that its arguments are without merit.

With regard to SEA 20, the Court has reviewed the record and the arguments of the parties and concluded that substantial evidence exists to justify the findings that were made by the Board in approving modifications to that SEA.

DID THE EIR ADEQUATELY ANALYZE THE SPECIFIC PLAN'S EFFECT ON THE SALT CREEK CORRIDOR?

Petitioners, Ventura County, et al., and United Water Conservation District (hereafter collectively "Ventura County") argue that the EIR did not adequately analyze and identify the Project's impact on the Salt Creek biological corridor in Ventura County. They argue that the Project will create an urban barrier drastically narrowing the movement of wildlife from the Los Padres National Forest north of the Project across the Santa Clara River and into the Santa Susana Mountains south of the Project. They conclude, therefore, that all of the wildlife movement, which now occurs over a 2.1 to 5.1 mile front, will be channeled to the Salt Creek Corridor, which the Los Angeles County Board of Supervisors has characterized as a "critical component of the Open Area system within the Newhall Ranch property . . . ." Petitioners point out that despite this characterization the Board "deferred analysis of the extension of the Salt Creek corridor in Ventura County to 'future action' that may be taken by Ventura County." Petitioners argue that since the Los Angeles County Board found that "the impact of the revised Specific Plan on biological resources would remain individually and cumulatively significant" even

/ / /

after mitigation measures, the Board was required to "adopt all feasible measures that would mitigate those impacts." (Relying on CEQA Guidelines, § 15092.)

Respondents point out that in the Final Plan the Los Angeles portion of the Salt Creek corridor was widened considerably. They point to the Administrative Record:

> To understand the role that the Salt Creek corridor plays in animal movement, one must understand that this corridor is but one small part of a larger regional wildlife movement interface that exists between the Los Padres/Angeles National Forest and the Santa Susana Mountains that spans a distance of approximately 35 miles . . . . [T]he Newhall Ranch Specific Plan site is only an approximately 2 to 5 mile-wide portion . . . of this 35-mile wide interface. Clearly, the Salt Creek corridor is just one of many such corridors which exist in this very broad interface area.

(A.R. 488.) They then point to the conclusion in the EIR that:

> [B]ecause the Newhall Ranch Specific Plan does not propose development in the Ventura County portion of the corridor and no other development activity has been proposed there, and because the Specific Plan now incorporates a ½ -mile wide setback from the County line which will allow for animal movement between the River and High Country in Los Angeles County, and because many more connections similar to Salt Creek occur along the 35-mile wide interface area, no significant impact would occur due to the Newhall Ranch Specific Plan which would require mitigation in Ventura County.

(A.R. 493-494.)

The problem is that, since Respondents undertook no study of the portion of the Salt Creek corridor lying in Ventura County to ascertain the effect of the restriction of movement of wildlife for 2.1 to 5.1 miles east of that corridor, there is no substantial evidence to justify the finding reached in the EIR in this regard. Since the EIR concludes that the wildlife movement will be focused toward the west side of the Project down Salt Creek, it is clear that the lack of a study of the Ventura County portion of the Salt Creek corridor leaves a vacuum in the record concerning the impact of that westward shift of wildlife into the Salt Creek corridor.

/ / /

/ / /

/ / /

IS THE EIR LEGALLY DEFICIENT BECAUSE IT EMPLOYS A DIFFERENT AND LESS RIGOROUS TRAFFIC IMPACT ANALYSIS IN VENTURA COUNTY THAN IN LOS ANGELES COUNTY?

Ventura County argues that the FEIR adopted:

> [A]s the standard for a measurable traffic impact a specific plan contribution of more than 1 percent to arterial highways. (4596.) Hence, in Los Angeles County vehicle counts for those locations where the specific plan was found to contribute more than 1 percent to the total traffic volume were examined and feasible mitigation measures proposed. However, the traffic analysis in Ventura County was stopped at Highway 126 . . . and Highway 23 . . . even though the Project traffic still greatly exceeded 1 percent of the total traffic. No Project traffic analysis was done for Ventura County arterial highways exiting SR-126 and SR-23.

Consequently, Ventura County contends that there is not substantial evidence for a finding as to Ventura County's arterial highways that significant traffic impacts identified in that County based on the 1 percent standard were mitigated, as was done in the Los Angeles County area based upon that same standard.

Respondents contend that they did not use a different standard in analyzing traffic impacts in Ventura County but rather used that same standard. However, they fail to demonstrate that is the case. As Ventura County points out, when the FEIR traffic analysis in Ventura County stopped on State Route 126, the Project represented 12.2 percent of the traffic and when it stopped on State Route 23, it represented 35 percent of the traffic.

The plan traffic analysis states:

> In all cases, a Specific Plan contribution of more than 1 percent is considered to be a measurable impact and is used as the impact criterion [for traffic analysis]. Hence, V/Cs [volume/capacity] for those locations where the Specific Plan contributes more that 1 percent to the total volume are examined and, if any of the above impact types are found, then the location is identified as being significantly impacted by the Specific Plan.

There being no evidence available in the Administrative Record to demonstrate that the local roadways exiting on State Routes 126 and 23 in Ventura County would not be

/ / /

impacted above 1 percent, there was no basis for the finding that traffic impacts would not be significant on those roads in Ventura County.

Given the Court's finding with regard to the inadequacy of the traffic study contained in the EIR, the argument concerning the traffic impact fee is moot.

WERE THE AIR POLLUTION MITIGATION MEASURES PROPOSED BY VENTURA COUNTY REJECTED WITHOUT SUBSTANTIAL EVIDENCE?

Ventura County points out that the Los Angeles County Board of Supervisors found that there would be unavoidable impacts on the air as a result of the Project. Petitioners argue that the Project will thus make it more difficult for Ventura County to attempt to meet State and Federal standards for clean air. Respondents, however, contend that the EIR demonstrates that:

> [O]n most days of the year, the Specific Plan's impact on Ventura County's air quality will be relatively slight. Under prevailing winds, 'Ventura County would receive a minimal impact (on the order of 1%) of the Newhall Ranch Specific Plan's emissions compared with the Santa Clarita Valley and Los Angeles County.' (A.R. 410.)

The Court finds on the totality of the record with regard to the issue of air pollution that substantial evidence supports the finding of the Board in its rejection of the mitigation measures proposed by Ventura County.

IS THE EIR LEGALLY DEFICIENT BECAUSE IT DOES NOT EVALUATE OR MITIGATE THE REASONABLY PERCEIVABLE IMPACTS OF CONTAMINATED STORM WATER RUNOFF ON WATER QUALITY?

Petitioner Ventura County argues that the FEIR is legally deficient for failure to evaluate or mitigate the reasonably foreseeable impacts of contaminated storm water runoff on water quality in the Santa Clara River watershed. Pointing to the NPDES's permit which calls for coordination among the City of Santa Clarita, the County of Los Angeles and Ventura County in developing and implementing a future storm water management plan for the watershed, Ventura County argues that all that has been developed by way of mitigation of potential storm water pollution has been a piecemeal approach to the problem and:

> [A]s a result, the FEIR mitigation measures regarding potentially contaminated storm water runoff are inadequate to mitigate to a level below significance the potential Project storm water impact on the watershed as a whole.

Respondents reply that they have neither piecemealed nor deferred (as the amicus brief of the Attorney General suggests) arguing, inter alia:

> As described in the EIR, the County found these deferral arguments inappropriate given that the Specific Plan contemplates future subdivision maps where, appropriately, on-site drainage systems would be designed and engineered. Specifically, the EIR states that:
>
> > 'Because NPDES is a federal law, future subdivisions within the Specific Plan would be subject to all applicable future rules and requirements of the program, which occur over time. It is premature to apply specific BMPS to the Specific Plan at this time because the on-site drainage systems, which dictate the placement, sizes and types of BMPs have not yet been designed and engineered. Also, as development occurs in Newhall Ranch, new and improved BMP technologies are likely to be available as more experience is gained in the NPDES program nationally.'

Substantial evidence appears in the Administrative Record to justify the findings of the Board with regard to the issue of storm water pollution. In this case, given the need to tailor drainage systems to the specific subdivision in development, discussion of the drainage system and its impacts Project-wide were sufficient to allow proper input during the process of developing the EIR.

DOES THE EIR ADEQUATELY DEAL WITH ISSUES CONCERNING WATER SUPPLY FOR THE PROJECT?

A. <u>Does the Ruling in the *Stanislaus* Case Mandate Rejection of the Water Supply Approach Utilized in the EIR</u>?

All petitioners, save the Vega petitioners and the Attorney General in his amicus brief, raise similar concerns about the adequacy of the EIR's treatment of water issues.

Each petitioner addressing the water issues, as well as the Attorney General, place substantial reliance on the holding in *Stanislaus Natural Heritage Project v. County of Stanislaus*, *supra*, 48 Cal.App.4th 182. As we have previously discussed, in that case the proponents of the project took the position that, inasmuch as they were dealing with a project to be developed in tiers, it was sufficient to have the county deem the environmental effects of the specific plan to be significant, approve the specific plan, and then at a later time determine what the significant environmental effects of the specific plan were to be as construction approached on each phase of the project. Thus, the proponents set forth the various sources from which they hoped to acquire water for their project, analyzed the water needs for the built-out project, conceded that they had a firm water supply in hand only for the first five years of development, and successfully proposed to the board of supervisors (but not so successfully argued to the Court of Appeal) that adequate mitigation could be achieved by adopting a mitigation measure declaring that development requiring over a certain number of acre-feet per year of water would not be permitted beyond the five year build-out:

> [U]nless the applicant can show to the County's satisfaction that adequate water supplies have been made available, and that environmental impacts of those sources have been studied and mitigated per CEQA requirements.

(*Id.* at p. 195.)

In the instant case Respondents correctly argue that, unlike the proponents in the *Stanislaus* case, they have specifically identified their water sources, have detailed their water needs through build-out, and, they contend, have attempted to address the significant impacts of the utilization of the various water sources upon the environment. Consequently, although the *Stanislaus* analysis must be applied to certain aspects of the mitigation measures adopted in this case, the *Stanislaus* holding does not require the conclusion that the water needs analysis contained in the instant EIR simply constitutes an inappropriate deferral of an analysis of environmental impacts.

/ / /

/ / /

B. **Given That Respondents Have Adequately Identified the Source of the Water Supply Required upon Build-out, Have They Demonstrated That Sufficient Water Will Be Available from Those Sources?**

The revised Specific Plan calls for 17,680 acre-feet a year ("afy") of water (A.R. 767), from which the water needs are to be met by: (1) reclaimed water from the WRP; (2) water from Castaic Creek flood flows; and (3) water from the Valencia Water Company ("VWC"). Valencia Water Company, a subsidiary of real party Newhall, derives its water from groundwater pumping in the area, and from CLWA, which in turn receives its water from the State Water Project ("SWP"). The Project forecasts use of 5,344 afy from the WRP, leaving 12,336 afy to be obtained from flood flows and from Valencia Water Company. In dry years flood flows would not be available, unless they had been stored by injection into either the Alluvial or the Saugus aquifer. We will deal with that issue later. Consequently, in dry years the Project would need 12,336 afy from VWC. At the time of the adoption of the EIR, the CLWA had an entitlement to 54,200 afy of water from SWP each year. The various petitioners and amicus argue, however, that the SWP has never been in a position to deliver more than 50 percent of entitlement to its users, including CLWA. While Respondents contend that is not so, and that the reason that CLWA has never taken more than 50 percent of its entitlement has to do with its lack of need for that entitlement rather than its availability, Ventura County in its reply brief points out that:

> [T]here is nothing in the record regarding CLWA's *requested* deliveries compared to its *actual* deliveries of State water and certainly no evidence to support the suggestion that it can obtain as much of its entitlement as it requests.

Respondents have argued, extra the record, that subsequent to the approval of the EIR that which was projected in the EIR has happened, and CLWA has acquired an additional 41,000 afy. As several petitioners point out, we view the record as it exists at the time the document is adopted and not later. Moreover, as several petitioners have also argued, even assuming acquisition of 41,000 afy by CLWA, only 20,500 afy can be projected from that source based upon historical records. Thus, of a theoretical entitlement of 95,200 afy available to CLWA, only half that sum would be available in fact based upon the record before us, and of that sum only 35.9 percent would be available to VWC, which means, given the existence of currently pending, approved and recorded projects, and their demands upon VWC, the Project can only meet its water demands if it also utilizes flood flow from Castaic Creek.

In effect, Respondents argue that, assuming all of the above to be correct, they will be able to utilize flood flow from Castaic Creek to augment the SWP water supply because they will obtain their allotted share of the flood flow in wet years from CLWA and will inject the same into the Saugus aquifer. Since the approved Project requires that no additional groundwater be drawn to support the Project, there must be substantial evidence in the record to demonstrate that: (a) the flood flow in wet years will be available to Respondents for use on the Project, and (b) the Respondents' share of that flow can be safely stored by injection into the aquifer and then retrieved without undue environmental damage. Lacking such evidence, the only source available to meet SWP shortfalls will be pumping of groundwater in violation of the terms of the EIR.

Looking first to the resolution of the question whether the Castaic Creek flood waters will be reasonably available to Respondents, the Court agrees with Respondents that an EIR can project modification to agreements in the future. However, the status of the record in this case is such that there is no substantial evidence that modification of the agreement to allow withdrawal of the flood water and storage of Newhall's share of the flood waters is achievable. Assuming, however, that the modification can be done and storage can be achieved and that neither is a sufficient impediment to utilization of flood waters, the more complex problem involves the ability to store the flood waters in the aquifer.

At Administrative Record page 4786 the DEIR recognizes that "the ability of the Saugus Aquifer to receive the treated flows is also a constraint" but states that "Findings indicate that the Saugus Aquifer would be able to accept the treated flows . . . ." There is nothing in the record that supports a finding that a given volume of water can be stored in the Saugus aquifer. Respondents contend that since this is a "confined" aquifer, its capacity to store additional water is, in essence, unlimited. Indeed, in response to a comment that the Aquifer Storage and Recovery ("ASR") alternative will cause groundwater levels to "drop because of a decrease in the recharge rate," Respondents' response was:

> [T]he proposed use of ASR for Newhall Ranch would involve injecting water into the Saugus Formation, in which groundwater is confined under pressure. As a result of confinement and pressure, the Saugus aquifer is fully saturated and the water-level surface occurs at an elevation that is above the top of the aquifer. Even in dry years, therefore, the Saugus aquifer is "full" of water, but its capacity to store additional water is unaffected. An analogy for a confined aquifer in this situation is a pressurized gas cylinder that accepts increases in pressure by the addition of gas without changing shape or leaking.

(A.R. 789.) As the Court pointed out to Respondents' counsel at oral argument, that statement belies the laws of physics which hold that, while gases can be substantially compressed (indeed, until they achieve liquid form), liquid cannot be compressed, and thus the science of hydraulics is born.

Storage of water in the Saugus aquifer is also affected by the operation of the Alluvial aquifer, which Respondents assume is linked to it. Petitioner Ventura County questions how much water the aquifers can actually hold, and points out that the EIR does not demonstrate the ability of the Alluvial and Saugus aquifers to actually store such water.

Respondents' revised draft EIR states:

> The general lack of specific data on the potential interconnection [between the two aquifers], however, precludes a precise determination of potential effects on the Alluvial Aquifer. In the absence of these data, the hydraulic interconnection between the two aquifers is approximated in this analysis by simplifying assumptions for the properties of both aquifers. These assumptions are based on the professional judgment of CH2M HILL, the Specific Plan hydrogeologists, and result in an over exaggeration of the potential water-level decline in the alluvial Aquifer as a result of the ASR pumping in the Saugus Aquifer. The over exaggeration is deliberate to compensate for the lack of complete understanding of the potential flow between aquifers . . . .

(A.R. 4808.) Respondents take the position that their approach to ASR storage in the aquifers has been extremely conservative with only conservative assumptions being made.

It is not the job of the courts in reviewing an EIR to interpose their judgment in place of the approving authority, nor to rule on the adequacy of the evidence presented to that authority, save to conclude that there is substantial evidence in support of the authority's determination. However, since in this case there is an admitted lack of understanding as to the properties of the aquifers in question, any assumptions based upon professional judgments are merely guesses on the capacity of the aquifers which, if wrong, could substantially impact water availability to the Project and also the use of the aquifers by downstream users in Ventura County.[8]

This, then, leaves the proponents of the Project with water mitigation measure 4.11-6:

> Prior to recordation of any final subdivision map that allows construction, and in accordance with the requirements of the Los Angeles County Development Monitoring System (DMS), as amended, Los Angeles County shall require the applicant of the subdivision to obtain written confirmation from the retail water agency that a water source is available to supply the subdivision concurrent with need. If the applicant of the subdivision cannot obtain confirmation that a water source is available for buildout of the subdivision, the subdivision shall be phased with the timing of an available water source.

This mitigation measure, standing alone, does not pass the scrutiny of a *Stanislaus* analysis. Consequently, the EIR is inadequate in its approach to the availability of water resources to supply its Project.

Because adequate water supplies have not been ensured, Los Angeles County has failed to comply with the requirements of the Development Monitoring System section of the General Plan as they relate to water supplies.

---

[8] See Public Resources Code section 21080, subdivision (e)(1), "For the purpose of this section and this division, substantial evidence includes . . . expert opinion supported by fact." See also *Gentry v. City of Murrieta* (1995) 36 Cal.App.4th 1359, 1422-1423.

CONCLUSION

Based upon the foregoing analysis, the parties to the various actions are entitled to relief as follows:

VENTURA COUNTY PETITIONERS

Petitioners are entitled to a Writ of Mandate stating:

1) Certification of the Final Environmental Impact Report ("EIR") for the Project is voided, but only with respect to the specific areas found deficient, as set forth in this Statement of Decision; and

2) Respondents and each named real party in interest and their respective agents, officers, employees, and all persons acting on their behalf or in concert with them, are directed and ordered to suspend any or all specific Project activity or activities that could result in an adverse change or alteration to the physical environment, until they have complied with the requirements of the California Environmental Quality Act ("CEQA") in the following respects:

   a. Determine the effect on that portion of the Salt Creek Corridor situated in Ventura County to be caused by the shifting of wildlife into the Salt Creek Corridor.

   b. Extend the traffic impact analysis employed in analyzing the Project in Los Angeles County to analysis of the impact of the Project on arterial roadways in Ventura County until the 1 percent impact standard is reached.

THE SIERRA CLUB

Petitioners are entitled to a Writ of Mandate stating:

1) Certification of the Environmental Impact Report for the Project is voided, but only with respect to the specific areas found deficient, as set forth in this Statement of Decision; and

2) Respondents and each named real party in interest and their respective agents, officers, employees, and all persons acting on their behalf or in concert with

them, are directed and ordered to suspend any or all specific Project activity or activities that could result in an adverse change or alteration to the physical environment until they have complied with the requirements of CEQA in the following respects:

a. Address the issue of adverse biological impacts on the river corridor based upon channelization and hardening of the banks.

b. Determine the effect on that portion of the Salt Creek Corridor situated in Ventura County to be caused by the shifting of wildlife into the Salt Creek Corridor.

3) Pursuant to the State Planning and Zoning Laws:

a. With regard to SEA 23, petitioners are entitled to a Writ of Mandate compelling Respondents and each named real party in interest and their respective agents, officers, employees, and all persons acting on their behalf or in concert with them to set aside their approval of the Newhall Ranch Specific Plan, General Plan Amendment 94-087-(5), Santa Clarita Areawide Plan Amendment 94-087-(5), Zone Change 94-087-(5) and Conditional Use Permit 94-087-(5), but only as those Project approvals relate to SEA 23 and the Los Angeles County's Development Monitoring System ("DMS") as it applies to water supplies. Respondents shall take action to ensure that the Newhall Ranch Specific Plan, General Plan Amendment 94-087-(5), Santa Clarita Areawide Amendment 94-087-(5), Zone Change 94-087-(5), and Conditional Use Permit 94-087-(5) are consistent with the General Plan policies of Los Angeles County requiring protection of natural resources in SEAs as they relate to SEA 23, and the General Plan policies relating to water supplies.

b. Petitioners are entitled to a Writ of Mandate compelling Respondents and each named real party in interest and their respective agents, officers, employees, and all persons acting on their behalf or in concert with them to suspend any or all specific Project activity or activities that could result in an adverse change or alteration to the physical environment unless and until they comply with the provisions of the Los Angeles County General Plan related to the Development Monitoring System as it relates to water supplies, and the General Plan policies of Los Angeles County requiring protection of natural resources in SEAs as they relate to SEA 23.

PETITIONERS VENTURA COUNTY, UNITED WATER, AND SIERRA CLUB

Petitioners are entitled to a Writ of Mandate stating:

1) Certification of the Environmental Impact Report for the Project is voided, but only with respect to the specific areas found deficient, as set forth in this Statement of Decision; and

2) Respondents and each named real party in interest and their respective agents, officers, employees, and all persons acting on their behalf or in concert with them, are directed and ordered to suspend any or all specific Project activity or activities that could result in an adverse change or alteration to the physical environment until they have complied with the requirements of CEQA and the State Planning and Zoning Laws in the following respects:

   Demonstrating that adequate water sources will be available for build-out of the Project, which may be achieved by securing other water sources consistent with CEQA, and/or by developing a factual basis providing substantial evidence from which the Board of Supervisors can adequately assess the environmental impacts of the employment of the ASR alternative and its ability to meet water needs.

ATTORNEY GENERAL AND THE SIERRA CLUB

The Writ of Mandate shall include an order stating:

1) Certification of the Environmental Impact Report for the Project is voided, but only with respect to the specific issues set forth in this Statement of Decision; and

2) Respondents and each named real party in interest and their respective agents, officers, employees, and all persons acting on their behalf or in concert with them, are directed and ordered to suspend any or all specific Project activity or activities that could result in an adverse change or alteration to the physical environment until they have complied with the requirements of CEQA in the following respects:

Address the alternative of siting the WRP off-river, including analyzing the biological impact of that siting, given that there is no substantial evidence to justify rejection of the off-river siting of the WRP.

RESPONDENTS

Respondents are entitled to the following relief:

1. That the Petition of the Vega petitioners be denied.

2. To a finding that the Subdivision Map Act does not require inclusion of Ventura County in the map approval process.

PREPARATION OF JUDGMENT AND WRITS

The petitioners shall prepare and submit a Judgement and a Peremptory Writ of Mandate consistent with this Statement of Decision.

Dated: 8-1-00

Subject: 2001 Update Report on the Hydrogeologic Conditions in the Alluvial and Saugus Formation Aquifer Systems — Job No. S9920

Dear Mr. DiPrimio:

We are pleased to present this 2001 Update Report on the Hydrogeologic Conditions in the Alluvial and Saugus Formation Aquifer Systems in the Santa Clarita Valley area of Los Angeles County, California. This project was undertaken to provide an update of our 1986 report of the alluvial aquifer system and our 1988 report on the Saugus Formation aquifer system.

This 2001 Update Report is provided as a two-volume set as follows:

- Volume I, which contains the Executive Summary, the report text in chapter format, and the supporting figures and tables.
- Volume II, which contains the report plates, in large-scale format, to support specific chapters of the report text; there are two sections to Volume II due to the large number of plates.

Volume I and the two sections of Volume II are separately bound.

It has been a pleasure to have worked on this investigation with you and the other Santa Clarita Valley Water Purveyors. This opportunity to have been of service is appreciated.

Very truly yours,
RICHARD C. SLADE & ASSOCIATES, LLC

Richard C. Slade, President

EXECUTIVE SUMMARY

This report presents our updated findings, conclusions and recommendations regarding the hydrogeologic conditions within the alluvial and Saugus Formation aquifer systems in the Santa Clarita Valley (Valley) of northern Los Angeles County, California. Figure ES-1 – Study Area Map – illustrates the approximate ground surface locations of the alluvial and Saugus Formation aquifer systems which are discussed herein. The report updates and expands upon two separate reports prepared by Richard C. Slade, Consulting Groundwater Geologist, on the alluvial and Saugus Formation aquifers, in 1986 and 1988, respectively. As such, this report supersedes those previous work products and is intended to provide the water purveyors in the Valley with a current assessment of the geologic and hydrogeologic conditions within the local groundwater basin.

The principal findings of this project include:

1. Data Compilation and Review

   Significant new data have been acquired that has greatly enhanced our understanding of the local groundwater basin. These new data cover a longer period of time, at a greater level of detail, and with more up-to-date information than previous data, and includes new types of information not previously available. The data are also representative of a broader geographic area of the Valley for both aquifer systems. These new data include information on water levels, water quality, downhole geophysical surveys (electric logs), driller's logs, flow meter surveys (spinner logs), depth specific water sampling, and injection and recovery testing.

   Historic and current data have been incorporated into a Geographic Information System (GIS) database, along with updated base maps and recent aerial photographs of the region.

2. Santa Clara River

   The Santa Clara River drains in a general east to west direction across the Valley. Annual runoff volumes within the river across the Valley have increased over time due to the increased use of imported water from the State Water Project (SWP water), and increased discharges from the two local water reclamation plants.

Figure ES-1
Study Area Map

Surface water runoff in the Santa Clara River drains into Ventura County at County line at the western end of the study area. This represents the only direct connection of surface water flow to Ventura County from the Santa Clarita Valley. The only direct connection of groundwater flow between the Valley and the downstream groundwater basins of Ventura County occurs at County line and only from subsurface outflow from the alluvium of the Santa Clara River.

3. <u>Geologic Setting</u>

The two principal aquifers in the Valley are (see Figure ES-1):

a) The blanket of unconsolidated alluvium of Quaternary geologic age deposited by the Santa Clara River and its tributaries, which covers the floor of the main river valley to a maximum thickness of approximately 200 ft. The alluvial aquifer consists of complexly interlayered and interfingered beds of gravel, sand, silt, and clay, which, due to their unconsolidated to poorly consolidated nature, and their lack of cementation, tend to have a relatively high permeability and porosity.

b) The considerably thicker, somewhat more consolidated sediments of the geologically older Saugus Formation (Pliocene to Pleistocene geologic age) that underlie the Quaternary Alluvium. The Saugus Formation can be subdivided into two stratigraphic units. The upper portion of the Saugus Formation is up to 5,000 ft thick and contains numerous coarse-grained sand and gravel beds that form the potential aquifer units. The lower portion of the formation, known as the Sunshine Ranch Member, is up to 3,500 ft thick, and does not contain groundwater in sufficient quantity or of adequate quality for municipal-supply purposes because it contains an abundance of fine-grained sediments of low permeability. The Saugus Formation has been deformed by folding and by faulting along the Holser and San Gabriel fault zones.

   A new geologic cross-section through the Saugus Formation has identified and correlated an important stratigraphic zone of coarse-grained sediments encountered in several existing water wells. This correlatable zone (informally termed the Santa Clarita Aquifer Zone), can be identified on electric logs over a wide area of the Valley. The Saugus Formation water wells with the highest pumping rates generally tend to produce groundwater from within and stratigraphically above the Santa Clarita Aquifer Zone.

4. <u>Local Groundwater Sub-basin</u>

In recent years, the California Department of Water Resources (DWR) has begun a process of updating the official names and locations of groundwater basins throughout the State, including the region along the Santa Clara River between the Santa Clarita Valley and the Pacific Ocean. Currently, the alluvial and

Saugus Formation aquifer systems in the study area are considered to lie within the Santa Clara River Valley East Groundwater Subbasin (East Subbasin) of the Santa Clara River Valley Groundwater Basin.

The western boundary of this local East Subbasin is currently taken at County line where it meets the adjoining (downstream) Piru Subbasin of Ventura County. The eastern boundary of the local East Subbasin occurs at a narrows near Lang Station.

5. Alluvial Aquifer System

A. *Groundwater Levels*

Groundwater in the alluvial aquifer occurs under unconfined (water table) conditions. In the western end of the East Subbasin, west of I-5, long-term water levels have remained generally constant over time in large part because of the naturally occurring upward flow of groundwater from the Saugus Formation into the overlying alluvium in this area. This provides a fairly consistent source of recharge that is relatively independent of annual rainfall trends.

In the central portion of the basin, between I-5 and the South Fork of the Santa Clara River, long-term water levels have become increasingly stable and now appear to be relatively insensitive to variations in annual rainfall. This is due in large part to the increased recharge provided to the alluvium from the two local water reclamation plants (WRPs) owned by the Sanitation Districts of Los Angeles County.

In the eastern portion of the alluvial aquifer (east of the South Fork of the Santa Clara River) water levels continue to display a much stronger correlation with annual rainfall totals than wells in the central or western parts of the Valley. Water levels decline temporarily during dry periods, but quickly recover to their pre-drought highs upon a return to wetter or even more normal climatic conditions.

Overall, there is no evidence of a long-term, continuous or permanent decline in water levels in any alluvial aquifer well, and thus no evidence that the alluvial aquifer is being pumped beyond its sustainable capacity (i.e. the aquifer is not in overdraft). While water levels in the alluvial aquifer do fluctuate over time, there is no continued and progressive decline in groundwater levels, leading to a permanent loss of groundwater in storage, which would be indicative of overdraft.

B. *Groundwater in Storage*

The alluvial aquifer contained an estimated 200,000 acre-feet of water in storage at its historical high in 1945, as reported by Slade in the original 1986 report on the alluvial aquifer system (Slade 1986 Report). In the spring of 2000, the total volume of groundwater in storage in the alluvial aquifer was approximately 161,000 AF. Over time, groundwater levels and associated groundwater storage in the alluvial aquifer have fluctuated, typically in response to wet and dry conditions as they affect water levels and storage in the eastern portion of the alluvial aquifer. However, there has been no long-term, progressive decline in the amount of alluvial groundwater storage that could be considered illustrative of overdraft conditions.

C. *Groundwater Production and Operational Yield*

Since the mid-1940s, annual groundwater production from the alluvium has ranged from a low of approximately 20,000 acre feet per year (AF/yr) in 1983, to a high of at least 44,000 AF/yr in 1955. The historically largest alluvial extractions occurred between 1951 and 1960, and between 1991 and 2000 (both are 10-year periods, during which the average annual pumpage was approximately 37,000 AF/yr and 35,000 AF/yr, respectively.

The annual groundwater production from the alluvial aquifer over the last ten years has averaged approximately 35,000 AF/yr, about 10 percent higher then the "practical or perennial yield" of 31,600 to 32,600 AF/yr calculated in the Slade 1986 Report. However, this increase in average production has occurred without any onset of undesirable conditions such as lowered water levels that might be indicative of overdraft. The primary reason that the alluvial aquifer has been able to supply groundwater in volumes that are well in excess of its previously estimated perennial yield for the past ten years is that imports of SWP water into the Valley have risen from approximately 1,100 AF/yr in 1980 to over 32,000 AF/yr in 2000. Much of this additional water is returned to the alluvial aquifer in the form of discharge from the two WRPs located along the Santa Clara River.

One of the disadvantages of utilizing perennial yield as a basis for managing the pumpage from an aquifer system is that it represents a long-term average value for annual yield. There is a potential for the perennial yield value to be interpreted as a "not-to-exceed" volume, with a related potential for pumpage above the perennial yield value in any given year to be incorrectly interpreted as "overdraft". A recently advanced concept intended to deal with such misinterpretations is that of operational yield. Operational yield can be defined as a fluctuating value of pumpage that may be above or below the perennial (or average) yield in any given year, and that varies as a function of the availability of other water supplies. The basic intent of the operational yield value is that it should not exceed the perennial yield of the groundwater basin over multi-year wet and dry cycles.

The operational yield concept includes flexibility of groundwater use by allowing increased pumping during dry periods and increased recharge (direct or in-lieu) with supplemental water when it is available in wet/normal rainfall periods. The operational yield protects the aquifer by helping to assure that groundwater supplies are adequately replenished on a long-term basis from one wet/dry cycle to the next. In the Valley, historical groundwater data demonstrate that the alluvium has been, and continues to be developed within its long-term sustainability (i.e. no continuous lowering of water levels, no notable trend toward degradation of groundwater quality, etc.).

It is evident from observation of the response of the alluvial aquifer system to average pumping over the last several decades, and response to pumping in individual years, that pumping from the alluvium can be performed at a higher average pumping rate and over a wide range of yearly pumping rates without inducing undesirable conditions that would be indicative of overdraft, i.e., long-term continuous and progressive decline in water levels and storage. This observation is particularly evident since the initiation of supplemental SWP water deliveries in 1980. As a result, the operational yield of the alluvial aquifer, or the yearly yield for operating purposes, could range from an individual annual pumping volume as low as about 20,000 AF to an individual annual pumping volume as high as about 45,000 AF. The ultimate goals would be to avoid short-term adverse impacts as a result of year-to-year fluctuations in pumping, and to avoid long-term adverse impacts such as continuously lowered water levels and reduced amounts of groundwater in storage.

Recognition of the historical response of the alluvium to the wide range of annual pumping and the higher average rate of pumping in recent years has led to the following two plans regarding operation of this aquifer system: 1) development of an Urban Water Management Plan (UWMP) in 2000 that includes water supply from the alluvial aquifer within both the long-term yearly operational range and the recent (last ten years) average pumping capacity; and 2) commitment via a Memorandum of Understanding (MOU) process between the Santa Clarita Valley Water Purveyors, Castaic Lake Water Agency (CLWA), and the downstream United Water Conservation District to develop a numerical groundwater flow model in order to analyze in greater detail how the alluvium can be operated in the future to optimize its yield without adverse impact to either the aquifer (avoidance of depressed water levels and depleted storage) or the environment associated with this aquifer (avoidance of decreased stream flows, avoidance of depleting riparian vegetation, etc.).

In summary, the combination of historical observations and current planning has led to the present conclusion that the alluvial aquifer system can be operated over a wide range of pumping volumes in any given year. As summarized in the 2000 UWMP, the operation of the alluvial aquifer will typically be in the 30,000 to 40,000 AF/yr range for most wet and normal rainfall years, with an expected reduction into the range of 30,000 to 35,000 AF/yr in dry years.

Given that the rate of alluvial groundwater extraction over the past ten years has averaged approximately 35,000 AF/yr and no long-term or permanent decline in water levels or groundwater in storage has occurred, the range of pumping proposed for the alluvial aquifer in the most recent UWMP is well within the operational yield of the aquifer.

D. *Water Quality*

The overall character of groundwater within the alluvial aquifer changes gradually from a calcium bicarbonate to a calcium sulfate character as the groundwater moves from east to west across the Valley. Alluvial groundwater in the tributary canyons in the western part of the area also tends to have a calcium sulfate character.

Concentrations of nitrate and total dissolved solids (TDS) in the groundwater within the alluvial aquifer system show measurable changes as one moves from the eastern to the western end of the Valley. In the eastern and central portions of alluvial aquifer (east of I-5) nitrate levels range from 14 to 27 milligrams per liter (mg/l), while west of I-5 they drop to less than 10 mg/l. TDS concentrations average approximately 550 to 660 mg/l in the eastern and central portions of the alluvial aquifer. TDS concentrations are highest in the alluvial groundwater west of I-5, averaging approximately 1000 mg/l TDS. Neither nitrate nor TDS concentrations exceed their respective State Primary or Secondary Maximum Contaminant Levels (MCLs) in any samples. Groundwater extracted in the area west of I-5 is used solely for agricultural irrigation, and not for municipal-supply purposes.

Between 1985 and 2000, even though some low levels of volatile organic compounds (VOCs) were detected in a few alluvial municipal-supply wells in the Valley, none of these VOCs was encountered at concentrations exceeding its respective MCL. There has been no detection of perchlorate (ClO_4, a component of rocket fuel) in any alluvial, municipal-supply water well in the Valley.

6. Saugus Formation Aquifer System

A. *Groundwater Levels*

Groundwater in the Saugus Formation occurs under semi-confined to confined conditions in the central part of the Valley, but is likely unconfined near the lateral margins of the Saugus Formation outcrop area. Historic static water levels in the Saugus Formation have typically fluctuated over time: the magnitude of these historic fluctuations varies from well to well, but has generally ranged from a minimum of 50 ft to a maximum of 175 ft; these water level conditions are for wells that typically range in total depth between 750 to 2000 ft. Long-term water level records show no evidence of a long-term or continuous decline in water levels in any Saugus Formation water well, and like the alluvial aquifer, the Saugus Formation aquifer is not in a condition of overdraft.

B. *Groundwater in Storage*

The amount of groundwater in storage in the Saugus Formation was calculated to be approximately 1.41 million AF, using an upper limit of 500 ft below ground surface (bgs) as part of the calculations, as reported by Slade in the original 1988 Report on the Saugus Formation aquifer system (Slade 1988 Report). More recent information on the thickness of the alluvium and the degree of potential drawdown interference between adjacent Saugus Formation and alluvial water wells has led us to adjust this upper limit from 500 ft bgs to 300 ft bgs. Updated calculations of groundwater in storage reveal a value of approximately 1.65 million AF, an increase of about 18% more than the 1.41 million AF calculated in the original Slade 1988 Report. This increase is due almost entirely to raising the upper limit of our depth zone for calculations from 500 ft to 300 ft bgs.

C. *Groundwater Production and Operational Yield*

Groundwater production from the Saugus Formation has averaged approximately 8,600 AF/yr from 1991 to 2000, with the highest ever historical production of approximately 15,000 AF/yr occurring in 1991, towards the end of a multi-year drought. No long-term continuous or permanent decline in either water levels or the amount of groundwater in storage has occurred under this historical range of pumping. In summary, the combination of historical observations and current planning has led to the present conclusion that the Saugus Formation aquifer system can be operated on a long-term average basis in the range of 7,500 to 15,000 AF/yr. Infrequently, during dry periods of one to three years, pumping extractions from the Saugus Formation can be ramped up from 15,000 to 25,000 AF/yr, and ultimately to 35,000 AF/yr if dry conditions continue. These latter increases would be temporary and would return to or below the historical range of 7,500 to 15,000 AF/yr once rainfall patterns returned to normal.

As summarized in the 2000 UWMP, the operation of the Saugus Formation aquifer system will typically be in the 7,500 to 15,000 AF/yr range for most years of normal or wet conditions, with possible short-term increases in dry periods into the 15,000 to 35,000 AF/yr range. It is recommended that a program of enhanced water level and water quality monitoring accompany this incremental temporary "ramp-up" in groundwater production from the Saugus Formation. However, such a temporary increase in pumping over and above historic levels is unlikely to have an adverse impact on the Saugus Formation aquifer system, and in particular is unlikely to induce a permanent loss of groundwater from storage or a decline in water quality.

D. Groundwater Quality

Groundwater in the Saugus Formation varies in character from calcium-bicarbonate ($Ca\text{-}HCO_3$) along the South Fork of the Santa Clara River, to calcium-sulfate ($Ca\text{-}SO_4$) in the central part of the Valley, to sodium-bicarbonate ($Na\text{-}HCO_3$) further west within the central fault block. The TDS concentration of Saugus Formation groundwater typically ranges from 500 to 900 mg/l, which is below the maximum State Secondary MCL for TDS of 1000 mg/l. We have performed a recent re-examination of water quality data for possible historical trends in TDS concentrations in the Saugus Formation. This revealed that although there has been a slight increase in TDS concentrations in most Saugus Formation wells in the past 40 years, this increase could not be correlated with increased groundwater production. On the contrary, there is evidence that TDS concentrations have actually decreased during periods of increased Saugus Formation groundwater production.

VOCs generally have not been detected in Saugus Formation groundwater, with the exception of four Saugus Formation water wells in the eastern part of the Valley. In these few wells, certain VOCs (primarily TCE) and the inorganic compound perchlorate have been encountered. None of the four impacted wells has been used for municipal-supply purposes since perchlorate was first detected in each of these wells in 1997. Results of ongoing laboratory testing of the other eight active Saugus Formation municipal-supply wells have all shown non-detection of perchlorate. Steps are currently being taken by the water purveyors to safely restore the capacity of the four impacted wells.

7. Artificial Recharge

Temporary fluctuations in water levels in the alluvial aquifer east of Bouquet Canyon create temporary groundwater storage capacity that could potentially be refilled faster than occurs naturally through a program of artificial recharge via spreading basins adjacent to the Santa Clara River. Excess flood flows in the Santa Clara River that would otherwise flow out of the Valley could be diverted to spreading basins where the water would percolate into and provide additional groundwater recharge to the alluvial aquifer. The purveyors may want to consider a range of recharge programs to augment the management of groundwater in the Valley.

In the Saugus Formation, recent field testing and groundwater modeling has demonstrated that Aquifer Storage and Recovery (ASR) using deep injection wells is feasible and potentially advantageous in terms of overall groundwater management for the local sub-basin. An ASR project of a scope beyond that envisioned for the Newhall Ranch development may provide further benefits to the Saugus Formation, including increased volume of groundwater in storage, more rapid post-drought recovery of water levels, a possible improvement in the groundwater quality in the Saugus Formation (depending on the source of the injection water), and greater flexibility in the operations and management of the local groundwater sub-basin by the local water purveyors.

8. Groundwater Monitoring

Although a specific basin monitoring program has not been developed as part of this update report, it is expected that the database developed for this report will become the basis for the evolution of historical data collection and recording into a formal program of monitoring, data collection, and database maintenance. These monitoring efforts have actually begun in a cooperative and integrated manner along the entire Santa Clara River as a result of the MOU between the Santa Clarita Valley Water Purveyors and United Water Conservation District.

Data to be collected and interpreted in the MOU process, as part of ongoing groundwater management, should include:

a) Static and pumping water level monitoring in wells in both the alluvial and Saugus Formation aquifers.

b) Water quality data monitoring from wells in both aquifers and for surface water in the Santa Clara River and its major tributaries.

c) Rainfall records.

d) Annual groundwater production volumes by individual wells from all of the major water users, including private and agricultural users.

e) Detailed well construction information for new and existing wells.

f) Records of any well destruction activities, including the dates and methods used.

g) Historic data on aquifer parameters, as well as newer data acquired during well construction and testing.

h) Information on potential groundwater contamination sites obtained from available government and/or private databases and publications.

i) Discharge volume and water quality data for existing and future WRPs.

j) Other relevant data, such as major changes in land use.

9. Conjunctive Use and Management of the Alluvial and Saugus Formation Aquifers

Conjunctive use refers to the coordinated management and operation of multiple water supplies to achieve improved reliability of the water supply. In this aspect, the Santa Clarita Valley is fortunate to have two local aquifers that can be conjunctively used with imported SWP water to provide the Valley with a reliable supply of potable drinking water.

Since beginning to import a supplemental surface water supply in 1980, the Santa Clarita Valley Water Purveyors have been conjunctively utilizing that imported surface water with local groundwater from the alluvial and Saugus Formation aquifer systems. These conjunctive use efforts have allowed increasing water demands to be met while maintaining groundwater production within a range that precludes either aquifer from being in overdraft. A similar, but expanded, conjunctive use program, as described in detail in the 2000 UWMP, is expected to integrate additional supplemental sources of water supply in order to meet further projected increases in water demand while maintaining both aquifer systems within long-term sustainable yield, i.e. no overdraft.

A conjunctive use strategy for the Santa Clarita Valley could include:

a) Utilizing a combination of imported SWP water and groundwater from the alluvial aquifer during periods of average or above average rainfall (normal and wet years).

b) Increased pumping of the Saugus Formation during periods of lower than average rainfall in the valley (dry years), or during periods of decreased SWP water availability.

c) Enhancing the recovery of water levels and storage volume in the Saugus Formation through a program of artificial recharge, via injection, whenever additional water supplies are available.

d) Increasing the available storage capacity of the alluvial aquifer through increased pumping in the area east of Bouquet Canyon. This would serve to enhance both the natural recharge to the aquifer, and the effectiveness of an artificial recharge program using surface spreading basins in the same area.

SECTION 1

INTRODUCTION

Presented in this 2001 update report are our findings, conclusions and recommendations regarding the hydrogeologic conditions within the alluvial and Saugus Formation aquifer systems in the Santa Clarita River Valley of northern Los Angeles County, California. As shown on Figure 1.1 – Location Map – the area covered by this report is centered near the City of Santa Clarita, and extends roughly 21 miles from the Los Angeles – Ventura County Line on the west, to the town of Lang on the east. In a north-south direction, the study area extends approximately 13 miles from the intersection of Interstate 5 (I-5) and State Highway 14 on the south, to Castaic Dam on the north.

Purpose and Scope of Services

This hydrogeologic study has been undertaken to update and expand upon two previous reports which were originally prepared for the Upper Santa Clara Water Committee (USCWC) by Richard C. Slade, Consulting Groundwater Geologist: the December 1986 report entitled *Hydrogeologic Investigation, Perennial Yield and Artificial Recharge Potential of the Alluvial Sediments in the Santa Clarita River Valley of Los Angeles County, California* [known as the Slade 1986 Report]; and the February 1988 report entitled *Hydrogeologic Assessment of the Saugus Formation in the Santa Clara Valley of Los Angeles County, California* [known as the Slade 1988 Report]. Specifically addressed in this 2001 update report are: updated geology and aquifer parameters; groundwater levels and groundwater quality in both the alluvial and Saugus Formation aquifer systems; an updated calculation of groundwater in storage in both aquifer systems; a discussion of the operational yield of both aquifer systems; and general considerations for conducting ongoing monitoring of both aquifers in the future, including data collection and management.

This project has been conducted for the water purveyors operating in the Santa Clarita Valley. These purveyors include four retail purveyors of domestic water and the Castaic Lake Water Agency (CLWA), which has a contract with the State of California to obtain water from the State Water Project (SWP) and which furnishes SWP water to these four retail purveyors. The four retail purveyors of domestic water are: Los Angeles County Water

Works District (LACWWD) No. 36 – Val Verde the Newhall County Water District (NCWD), the Santa Clarita Water Company (SCWC), a Division of CLWA, and the Valencia Water Company (VWC).

A summary of the hydrogeologic work tasks undertaken for this report is as follows:

Task 1 Acquisition of Basic Data

A. Recent geologic and hydrogeologic data and reports.
B. Precipitation data.
C. Water level data for alluvial and Saugus Formation water wells
D. Water quality data for alluvial and Saugus Formation wells.
E. Annual groundwater production data for alluvial and Saugus Formation wells.
F. Well construction and pump installation details for alluvial and Saugus Formation wells.
G. Accurate locations and wellhead elevations for alluvial and Saugus Formation wells.
H. Electric logs for new water wells and for additional wildcat oil wells.

Task 2 Production of Geographic Information System (GIS) Base Map and Digital Database

A. Acquisition of base map components including digital street data, topographic contours, rivers, etc.
B. Digital aerial photographs for land use evaluation.
C. Compile, verify and input data from Task 1 into electronic database and/or GIS format.
D. Import Global Positioning System (GPS) survey results of water well locations for the major purveyors in the Valley into GIS format (GPS survey carried out by others).
E. Update and digitize selected information from maps presented in the Slade 1986 Report and the Slade 1988 Report, and import into the new GIS format.

Task 3 Field Reconnaissance

A. Field reconnaissance of selected alluvial-supply water wells to collect non-pumping water levels.

B. Field reconnaissance of selected Saugus Formation water wells to collect non-pumping water levels.

Task 4 Current Land Use Patterns

Using aerial photography and the GIS system, identify and digitize the general location and extent of various land use types.

Task 5 Hydrogeologic Analysis

A. Identify local groundwater basins.

B. Discuss basic geologic conditions.

C. Review and re-define (as needed) key parameters for the alluvium and/or Saugus Formation, including thickness, extent, and depth to the base of fresh water, based on drilling and electric log data acquired since the mid-1980s.

D. Reinterpret existing and newly acquired electric logs from the Saugus Formation to identify key intraformational stratigraphic marker units.

E. Update existing geologic cross-sections, and construct new cross-sections.

F. Prepare and evaluate updated water level hydrographs (where possible) for selected municipal- and irrigation-supply wells.

G. Prepare and evaluate updated rainfall graphs.

H. Prepare and evaluate updated graphs of specific capacity (where possible) for selected municipal- and agricultural-supply wells.

I. Prepare updated water level elevation contour maps for both the alluvium and the Saugus Formation.

J. Re-assess aquifer transmissivity values for the alluvial and the Saugus Formation aquifer systems.

K. Update calculations of groundwater in storage for the alluvial aquifer and the Saugus Formation.

L. Provide recommendations for areas in the alluvial aquifer where artificial recharge projects might be considered.

M. Re-assess the Slade 1986 Report estimate of the operational yield of the alluvial aquifer.

N. Re-assess the Slade 1988 Report estimate of potential groundwater extractions that might be possible for the Saugus Formation on both short- and long-term periods.

O. Develop a program for groundwater monitoring within the Valley.

Task 6 Report Preparation

Prepare the updated hydrogeologic report, including large-format maps and a digital GIS-compatible database.

Task 7 Meetings

Prepare for and attend meetings with the local water purveyors.

Sources of Data

One of the most ambitious goals of this project has been the research and compilation of a digital dataset that brings together available information pertaining to groundwater in the Valley. Included in this dataset are details of water well construction, annual groundwater extractions, historic groundwater levels and groundwater quality, and both surface and subsurface geology, all in a format compatible with commonly available GIS software.

This unified digital dataset provides a number of significant benefits, in that it:

- Serves as a common, easily accessible source of information and data on groundwater in the Valley.
- Facilitates the cooperative and ongoing management of groundwater resources among the various purveyors.
- Reduces the time required to prepare future annual water reports.
- Facilitates planning and siting of new wells, and the destruction of old ones.
- Simplifies the analysis of wellhead protection/vulnerability studies.
- Greatly simplifies the distribution of data to consultants retained by the member water agencies.
- Facilitates detailed, accurate and rapid analysis of groundwater and geologic data.
- Allows new data to be rapidly incorporated into existing datasets.
- Permits the transfer of data to and from groundwater modeling software.
- Allows groundwater maps be created, updated and printed in hours instead of days or weeks.

Previous Studies

Because the study area overlies several producing and former oil fields, there exist numerous published and unpublished geologic reports and maps dealing with surface and subsurface geologic conditions in the hills and mountains surrounding the Valley. The earliest works date from the period 1902 to 1924 (importantly, Kew, 1924) and document the initial efforts at naming and mapping the surface exposures of the stratigraphic units and geologic structure in the region.

With the discovery of larger oil fields between the late-1930s and the late-1940s, there was a renewed interest in the geology and the potential for additional petroleum development. Mapping by such workers as Bailey (1954) and Crowell (1954) added considerable detail to the known stratigraphy and to major geologic structures like the San Gabriel fault. Other particularly significant geologic reports include those by Winterer and Durham for the U. S. Geological Survey (1962) and by Oakeshott (1958) for the California Division of Mines and Geology. More recent studies include university theses by Nelligan (1978) and by Stitt (1980).

Considerable information is available to document the history of oil field development in the greater Santa Clarita Valley region. The majority of these reports have been published by the California Division of Oil and Gas. From its Ventura office, the Division of Oil and Gas maintains comprehensive files on the well histories and geophysical electric logs for the large number of existing and former wildcat and producing oil wells in the region.

In contrast to the geology and oil well data, published hydrogeologic and hydrologic information for the region is not nearly as abundant. With the exception of the Slade 1986 Report, the Slade 1988 Report, and the Los Angeles County Flood Control District (LACFCD) annual maps of the region showing water level data for key wells, there have been no previously published studies detailing aquifer characteristics, water well construction and testing, water level elevation fluctuations, or water quality variations in water wells throughout the region.

Previous assessments of the local hydrogeologic conditions are limited to those by: Robson (1972) for the U.S. Geological Survey, which provided the results of an analog computer model of the Saugus-Newhall area; the 1979 State Department of Water Resources (DWR) report, which provided a reconnaissance-level evaluation of the potential for storing excess water from the SWP within the several groundwater basins located along the Santa Clara River in Los Angeles and Ventura counties; the Department of Water Resources (DWR, 1975 and 1980) which identified the boundaries of the various groundwater basins in the region; and numerous maps by the LACFCD which provided water level elevations contour maps for various years.

Many of the references listed above are cited in the Slade 1986 Report and/or the Slade 1988 Saugus Report. Key references specifically cited in this 2001 update report are provided herein in Section 7 – References Reviewed.

Water Wells

Well construction details were obtained from a variety of sources, including the Slade 1986 Report, the Slade 1988 Report, other in-house reports and files for other projects by this investigator subsequent to 1988 for the area, the local major Santa Clarita Valley Water Purveyors, and from State water well completion reports. In some cases, particularly with older or privately-owned wells, information on well construction details was often unavailable.

As of 2001, a total of 30 deep Saugus Formation water wells had been drilled and constructed for municipal-supply and/or irrigation-supply purposes in the Valley. Of these wells, 13 have been abandoned and/or destroyed, whereas the remaining 17 either have remained in operation or are on inactive or standby status. Also as of January 2001, there were 61 currently active alluvial water wells in the Valley; of this number, 37 were used for municipal-supply purposes and 24 were used for irrigation-supply by the Newhall Land & Farming Company (NLF), the largest agricultural user of groundwater in the Valley. The number, usage, viability and location of small, individual, domestic-supply water wells in the alluvial and Saugus Formation aquifer systems in the region are unknown.

Electric logs (e-logs) are available for nearly all of the currently active Saugus Formation water wells, as well as for a number of the currently active municipal-supply alluvial water wells.

An attempt was made to determine the correct and/or complete State Well numbers (SW Nos.) and Los Angeles County Flood Control District numbers (LACFCD Nos.) for wells owned by the major purveyors in the study area. It was hoped this would permit the use of water level records maintained by these agencies together with those maintained by the U.S. Geological Survey (USGS) and LACFCD. Unfortunately, the database of SW Nos.

maintained by the DWR is incomplete and in some cases contradicts other sources of information. The LACFCD records are equally lacking, and although a few SW Nos. and LACFCD Nos. have been updated, there are still numerous wells for which these data remain incomplete. As a result, we are relying in this report solely on the well name or well number designated by its owner for each well discussed in this report.

One major improvement in data collection reflected in this report has been the accurate surveying of the locations of the known Santa Clarita Valley Water Purveyor water wells, as well as a number of other important wells in the area. The surveying program was carried out in December 1999 by Penfield and Smith Engineers & Surveyors, Inc. using a GPS receiver. A total of 99 wells were surveyed.

The GPS receiver used for this study was a Trimble Pathfinder Pro/XRS, and the locations were differentially corrected to a theoretical horizontal accuracy of ±1 meter horizontally and ±2 to 3 meters vertically. Well locations were stored in a Microsoft Access 2000 database in latitude/longitude coordinates, NAD83 datum, and random field checking of these locations by us and others, has revealed them to be accurate for the purposes of this project. However, in reviewing the positional data, errors in the vertical elevation of several wells were discovered because certain wellhead elevations derived from the GPS survey did not agree with the elevation of the ground surface as shown on the USGS 1:24,000 scale topographic contour maps. In these cases, the well elevations were adjusted to match the published USGS digital elevation map.

The positions of historic wells that were destroyed prior to 2000 were digitized from the original Mylar maps that were used in publishing the Slade 1986 Report and the Slade 1988 Report. The locations shown on the current maps for these historic wells are only approximate.

Groundwater Extractions

For the period from 1947 to 1984, groundwater extraction data were available only as a yearly value for each purveyor. Although the database of groundwater production contains some individual well data prior to 1984, those data should not be used to calculate total production figures. The total groundwater production from 1947 to 1966 is a minimum figure, because the only complete production records for this early period are those from NLF; during that period, NLF–owned water wells extracted the majority of the groundwater production from the local aquifer systems.

From 1984 to the present, groundwater production data are generally available for the individual municipal-supply wells on a yearly basis. The acre-feet per year (AF/yr) values for the NCWD, SCWC and VWC wells are from metered production at each well. For the NLF wells, the reported extractions were estimated from kilowatts of power consumed converted to AF/yr by reference to the results of annual Edison efficiency tests. For the Wayside Honor Rancho (WHR) wells, the actual quantity of water pumped is not known because the individual wells at that facility are not metered. Instead, the annual extractions reported for WHR are based on their estimated water consumption using an estimated number of prisoners and staff using the facilities.

Water Levels

Static water level data supplied by the water purveyors for this project vary considerably in quality and completeness. In some cases, static water levels have been measured on a consistent, once-per-month basis and stored in a regularly updated digital database. In other cases, water level measurements have been taken sporadically or not at all, and data gaps of a few months to several years in duration may exist in the historical records. For this report, available pumping and static water level data for wells in both the alluvial and Saugus Formation aquifer systems have been entered into a Microsoft Access database. In addition, customized queries and reports have been written to provide tables of water level data, and to prepare water level hydrographs for individual wells.

For the alluvial aquifer, the extent of available water level data is as follows:

- A dataset for thirteen of the SCWC wells for the period from 1973 to the present.
- A dataset for eight of the NCWD wells covering the period from the early 1980s to the present.
- A dataset for the fifteen currently active VWC wells, from the early 1990s to present. In addition, some data exist for these same wells from the 1950s to the mid-1980s.
- Finally, for NLF wells, some data exist from the mid-1950s to the early-1980s, little or no data are available for the latter part of the 1980s, and data collected from

Edison Company well efficiency test records (which typically include a static water level data point) were obtained for the period from approximately 1990 to the present.

The alluvial aquifer water level data described above were compiled from our in-house files, purveyor water level records, and available Edison test datasheets. Recorded static water levels in some cases may represent partially recovered, post-pumping water levels, especially for active NCWD wells.

For the Saugus Formation, the extent of available water level data can be summarized as follows:

- A dataset for six of NCWD's Saugus Formation wells from the mid-1980s to the present.
- A dataset for the two SCWC Saugus Formation wells from their construction in the late-1980s to the present.
- A dataset for VWC Well Nos. 157 and 160 from the early-1950s to the present
- Limited available information on water levels for VWC Well No. 159 from 1992 to the present.
- A dataset for VWC Well No. 201 from 1990 to the present.
- For NLF Well No. 156, some data exist from the mid-1950s to the early-1980s, little or no data are available for the latter part of the 1980s, and a few once-per-year Edison test records were obtained for the period from approximately 1990 to the present.

The Saugus Formation water level data described above were compiled from our company files, purveyor water level records, and available Edison test datasheets. Water levels in some cases may represent partially recovered, post-pumping water levels, especially for active NCWD wells.

Water Quality

Water quality data, including general mineral chemistry data on common dissolved cations and anions, as well as inorganics (metals), VOCs, and perchlorate, were obtained primarily from the local water purveyors. Some additional data were derived from our company files, and from the databases maintained by the California Department of Health Services (DHS) and DWR.

Because various agencies, including the DHS, require that drinking water sources such as water wells be tested on a regular basis, water quality data are readily available for the wells used by the various purveyors for municipal-supply purposes in the Valley. Considerably fewer water quality data are available for the NLF wells, because these are used only for agricultural-supply purposes.

Further groundwater quality data are available from a recent re-examination of available TDS data from Saugus Formation water wells in the Valley; this re-examination was carried out as part of a May 2000 presentation by our firm to the California Public Utilities Commission (PUC) on behalf of VWC. The original laboratory data were used to re-calculate TDS concentrations using a more standard, additive method described in a USGS report by Hem (1985). These data were then compared to historic pumping and water level records to look for possible trends in TDS concentrations over time, and to examine if these trends were related to changes in groundwater production.

Surface Geology

The geology of the study area was originally compiled from published sources and presented in the Slade 1986 Report and the Slade 1988 Report for the alluvial aquifer system and the Saugus Formation aquifer system, respectively. For this current update, the original geological units and features shown in those reports were digitized, and in some cases updated using newer published sources (for example, Dibblee, 1996). No major changes have been made to the original geologic maps, although some minor adjustments have been made to the boundaries of the alluvium unit, and to the degree of certainty attached to the mapped location of a portion of the Holser fault across a portion of the Valley.

Subsurface Geology

For the Slade 1988 Report, the subsurface geology of the Saugus Formation was compiled from published reports and from an examination of a few hundred e-logs from oil industry exploration and production wells. The locations of approximately 140 of these oil wells are shown on several maps in that Slade 1988 Report, along with various subsurface geologic contours (depth to the base of fresh water, the thickness of sand units in the Saugus Formation, etc.).

For this 2001 updated report, we have re-examined and re-interpreted the e-logs for each of the 140 oil wells depicted in the Slade 1988 Report (plus approximately 30 additional wells) in order to obtain more detailed subsurface geologic information for the Saugus Formation. The location of each of these wells has been digitized from the original 1988 report map, for use in the GIS system. From each of these approximately 170 e-logs, total sand thicknesses were re-calculated for the depth zone between 300 ft and 2500 ft below ground surface (bgs), or to the base of fresh water, whichever was shallower. Also re-calculated for each of these ±170 wells were the depth to the base of fresh water, the total Saugus Formation thickness, and the depth to the top of a prominent e-log marker bed unit within the Saugus Formation (herein termed the Santa Clarita Aquifer Zone). In addition, a new geologic cross-section Z-Z' (see Plate 3.3 in Section 3 of this report) that parallels the Santa Clara River has been completed across the area from east to west.

GIS Compilation

Data acquired and compiled for this report have been formatted for use with GIS software. This was done to facilitate the updating of maps with newly acquired or corrected data, and to utilize the powerful data manipulation abilities of GIS packages. To accomplish this objective, we first constructed a useable base map of the Valley, combining data from a wide variety of sources as described below.

Topographic contours for the base map were derived from USGS 1:24,000 scale digital elevation models, using TopoDepot, a commercially available software package produced by Sylvan Ascent Inc. of New Mexico. Although they vary slightly in detail from the contours found on printed USGS 1:24,000 topographic quadrangle sheets, the TopoDepot contours are considered to provide sufficiently accurate elevation data for the project area.

Hydrographic features for the base map (streams, reservoirs, etc.), and the Public Lands Survey System (PLSS) features (sections, townships & ranges) were taken from publicly available USGS Digital Line Graph (DLG) files downloaded from the USGS web site. The hydrographic features were digitized by the USGS from 1:100,000 scale topographic maps, and therefore tend to be somewhat generalized in appearance.

The PLSS data are much more accurate, but some caution must be exercised regarding their use with water well and oil well data provided by the State of California. The PLSS sections depicted on the maps supplied with this report include large blank areas where the PLSS system ends at the boundaries of the large historic Spanish land grants. Both the DWR and the Department of Oil and Gas have created artificial section lines that project across these land grant areas in order to assign State Well Numbers to water wells and oil wells. However, these different projections frequently fail to accurately line up with one another, and are therefore not compatible or interchangeable.

The road and freeway network in the Valley was obtained from the Los Angeles County Public Works Department (LACPWD) GIS system. The original data were accurate with respect to location, but contained numerous errors in attribute coding which required our firm to perform extensive editing and correction before use in our base map.

In order to review current land use patterns and distribution, high-resolution seamless color aerial photography covering the entire study area was obtained from Eagle Aerials Ltd. This photography is in digital format with an approximate 1 meter ground resolution, and was flown in June, 2000. Approximate land use polygons were digitized from the aerial photography, although the actual land use categories were not verified by field checking.

SECTION 2

AREA OF INVESTIGATION

Study Area

As shown on Figure 1.1 - Location Map - the roughly rectangular-shaped study area extends from approximately the Los Angeles– Ventura County line on the west, to the community of Lang on the east, and from the southern end of Castaic Lake on the north, to the intersection of the Golden State and Antelope Valley freeways on the south. The study area includes the valley of the Santa Clara River and its major tributary canyons, as well as a large area of rugged hills on the north and south sides of the river.

Elevations along the river valley range approximately from 1800 ft above mean sea level (asl) at Lang at the easterly limit of the region, to 800 ft asl at County line at the western boundary. The overall river gradient across this reach is on the order of 0.009 ft/ft (about 50 feet per mile). Maximum elevations in the hills north of the river are on the order of 2500 to 3000 ft asl, whereas maximum elevations to the south are typically 4000 ft asl in the San Gabriel Mountains and 3000 ft in the Santa Susana Mountains. The highest elevations in the region include Mt. McDill (5180 ft asl) in the headwaters of Mint Canyon north of the Santa Clara River, and Mt. Gleason (6532 ft asl) in the Condor Peak quadrangle south of the Santa Clara River and several miles southeast of the study area.

The largest community in the study area is the City of Santa Clarita, which was formed in 1987 through the amalgamation of the communities of Newhall, Valencia, Saugus, and Canyon Country. Other, smaller, unincorporated communities in the study area include Stevenson Ranch and Val Verde in the west, Castaic in the northwest, and Lang in the east.

The US 2000 Census revealed the population of the City of Santa Clarita to be approximately 151,260; see the approximate City limits on Figure 1.1. The Southern California Association of Governments (SCAG) estimates the population of the surrounding unincorporated Santa Clarita Valley at 48,237 (M. Modugno, City of Santa Clarita Planning Dept., personal communication, 2001); hence, the total current population of the Valley is approximately

200,000. This represents a significant increase over the 1980 Valley population of 79,000 reported in the Slade 1986 Report.

Accompanying this rapid population increase has been a gradual change in valley land use patterns, from largely agricultural use to urban and suburban developments. Nevertheless, a considerable portion of the hills and low mountains bordering the main river valley remain in a natural, undeveloped condition.

Climate

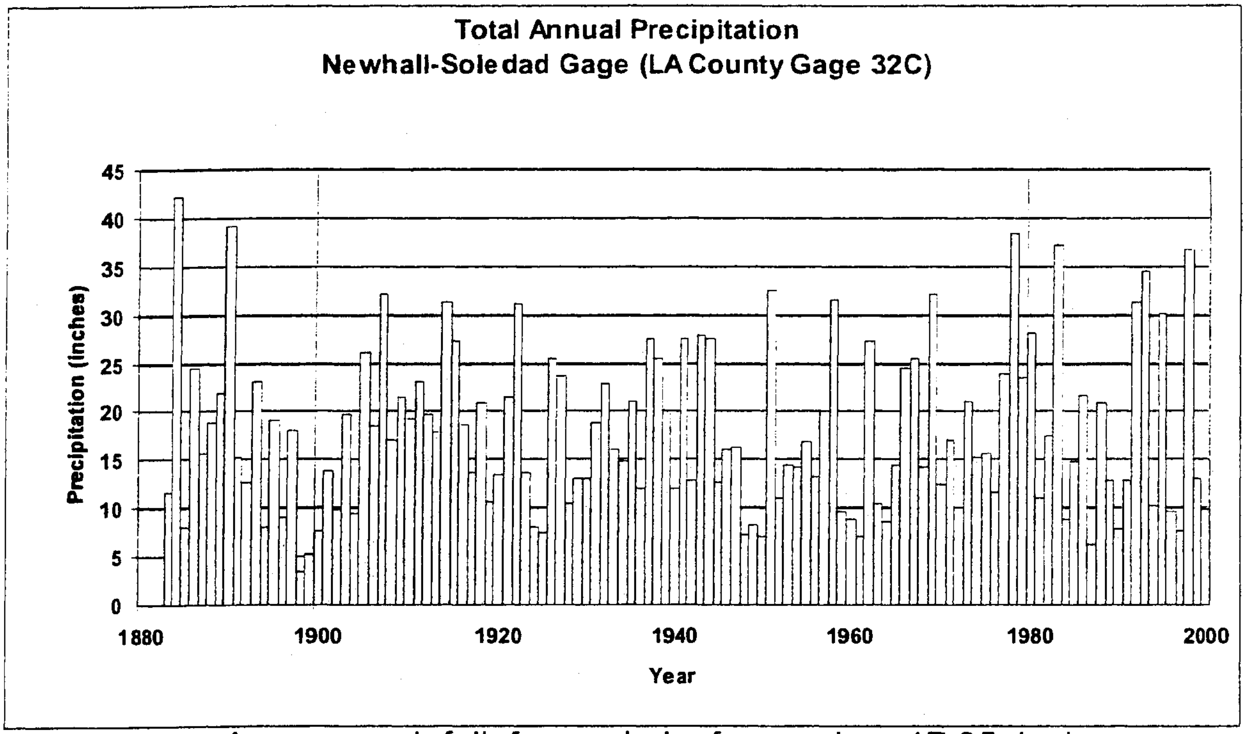
The study area has a semi-arid, Mediterranean-type climate characterized by long, dry summers and relatively short, wet winters. Temperatures in the Valley range from a maximum of approximately 100°F during the summer, to a minimum of 30°F in the winter. Mean monthly temperatures range between approximately 77°F in the summer, to 48°F in the winter.

Rainfall data have been obtained from LACFCD for the Newhall-Soledad gage (Station No. 32C), located near San Fernando Road in the community of Newhall. This gage has a period of record of 1883 to 2000. Unfortunately, the two rainfall gages (Stations Nos. 200 and 1009) discussed in the Slade 1986 Report have been discontinued. Figure 2.1 - Rainfall Totals and Cumulative Departure Curve – presents graphs of both the annual precipitation by water year (October to September), and the cumulative departure from the mean precipitation for the Newhall-Soledad gage.

Review of the rainfall data from the Newhall-Soledad gage reveals the following:

- the average rainfall for the 1883 to 2000 period of record (118 years) is 17.95 inches.
- the highest amount of annual rainfall for the period of record is 42.11 inches in 1884, whereas the lowest historic annual total is 3.32 inches in 1898.
- annual rainfall totals show high variability from year to year.

Approximately 80 percent of the annual precipitation in the Valley falls between November and March. Most of these winter storms last only a few days, and are separated by relatively long periods of clear weather.



Average rainfall for period of record = 17.95 inches

CONSULTING GROUNDWATER GEOLOGISTS

FIGURE 2.1
Rainfall Totals & Cumulative Departure Curve

JOB NO. S9920 June 2002

The cumulative departure curve for rainfall (see Figure 2.1) illustrates trends in the amount of rainfall over time, such that when the curve is descending towards the right (such as from 1890 to 1904, or from 1944 to 1965), an extended period of generally deficient precipitation (drought) has been occurring. In contrast, whenever the curve ascends to the right (such as from 1976 to 1983), an extended period of generally excess or increasing precipitation (wet period) has been occurring. As seen on the cumulative departure curve, the Valley has experienced episodic cycles of dry years followed by periods of wet years. However, these cycles show no discernable periodicity that might be used for predictive purposes.

Drainage

The Santa Clara River provides regional drainage in an east to west direction across this portion of Los Angeles County, and continues westerly across Ventura County to the Pacific Ocean. This river has its headwaters in Soledad Canyon in north-central Los Angeles County and includes a watershed area of several hundred square miles.

Principal tributaries draining the northern side of the study area include, from east to west, Mint Canyon, Bouquet Canyon, San Francisquito Canyon, and Castaic Creek Canyon. Principal tributaries draining the southern side of the Valley include, from east to west, Oak Spring Canyon, Sand Canyon, and Potrero Canyon.

The South Fork of the Santa Clara River, which drains in a northerly direction toward its confluence with the main reach of the Santa Clara River (located just west of Bouquet Junction), has Placerita Creek Canyon, Newhall Creek Canyon, and Pico Canyon as its main tributaries.

Because the headwater areas of these drainages do not extend into high mountainous areas, and because the local climate precludes the buildup of a large snow pack in the watersheds, surface water runnoff in all of the canyons is ephemeral and diminishes rapidly after most rainfall events. Local springs and areas of rising water, together with outflows from the local WRPs, tend to maintain flows even in the summer months within the main reach of the Santa Clara River west of Bouquet Canyon. Following severe storms, river discharge has been reported to increase from nearly zero flow to as high as thousands of cubic feet per second within a few hours.

The annual volumes of runoff in the river vary directly with annual rainfall, but, in general, are considered to have increased over time due to two man-made activities: the increased importation and use of water in the area from the SWP; and the increased releases, over time, from the two local WRPs. Surface water runoff from the river drains westerly into Ventura County at County line at the western edge of the study area for this project (see Figure 1.1). This represents the only direct connection of surface water flow between the Valley and Ventura County.

Local Water Purveyors

Domestic water purveyors located within the study area include LACWWD No. 36, NCWD, SCWC (a Division of CLWA), and VWC. These four domestic water purveyors and the CLWA make up the management committee for whom this report was prepared. LACWWD No. 36, SCWC and NCWD represent public agencies, whereas VWC is privately owned. Of the four domestic water purveyors, only LACWWD No. 36 has no active wells in either the alluvial or Saugus Formation aquifer systems within the study area.

In addition to the groundwater extractions by the local purveyors, supplemental water is provided to these purveyors for use in the Valley by CLWA via the SWP. SWP water, which is transported from the California Aqueduct, first became available to the Valley area in 1980. CLWA also delivers highly treated recycled water from one of the two WRPs in the Valley, owned by the Sanitation Districts of Los Angeles County, in order to help meet non-potable water demands (golf courses, landscape irrigation, etc.).

Groundwater Basins

The DWR establishes the official names and locations of groundwater basins throughout California (Bulletin 118). At the time of the original Slade 1986 Report and the Slade 1988 Report on the Valley, the alluvial and Saugus Formation aquifer systems were included within an area known as the Eastern Hydrogeologic Subunit of the Santa Clara River Valley Unit. In addition, these two aquifer systems were considered to represent the only two water-bearing formations within the Valley. For the purposes of this report, the water-bearing sediments comprising the alluvial and Saugus Formation aquifer systems are considered to be those earth materials that are capable of providing groundwater in useable quantities and of acceptable quality for beneficial use by the municipal-supply water purveyors. Underlying these water-bearing sediments beneath the Valley and also forming the lateral (surface) margins of the local groundwater reservoir is a very thick accumulation of older sedimentary rocks that are considered to be essentially nonwater-bearing in terms of their general ability to provide groundwater for municipal-supply purposes.

In recent years, DWR has begun a process of updating its Bulletin 118 and has provided new GIS-format maps of its updated basin boundaries and names. Figure 2.2 – Groundwater Basins and Sub-basins – depicts the location and current nomenclature for the official groundwater basins along the Santa Clara River between the City of Santa Clarita on the east and the Pacific Ocean on the west, as adapted from recent DWR work. The alluvial and Saugus Formation aquifer systems are now together considered to lie within the Santa Clara River Valley East Groundwater Sub-basin of the Santa Clara River Valley Groundwater Basin.

DWR basin boundaries were selected on the basis of such features as faults, groundwater divides, exposures of bedrock in the hills, or areas of rising water caused by the presence of bedrock shallowly underlying river alluvium. Where none of these types of conditions exist, arbitrary or even political divides were selected as boundaries between the aforementioned groundwater basins and subbasins.

The western boundary of the Santa Clara River Valley East Groundwater Sub-basin is currently taken at County line where it meets the adjoining (downstream) Piru Sub-basin of Ventura County. The eastern boundary of the local groundwater sub-basin occurs at a narrows along the Santa Clara River near Lang. Upstream (east) of the Santa Clara River Valley East Sub-basin, and separated by a gap of approximately three miles, is the Acton Valley Groundwater Basin.

The only outflow from the Santa Clara River Valley East Groundwater Sub-basin to Ventura County occurs via direct subsurface outflow from the saturated portions of the alluvial aquifer

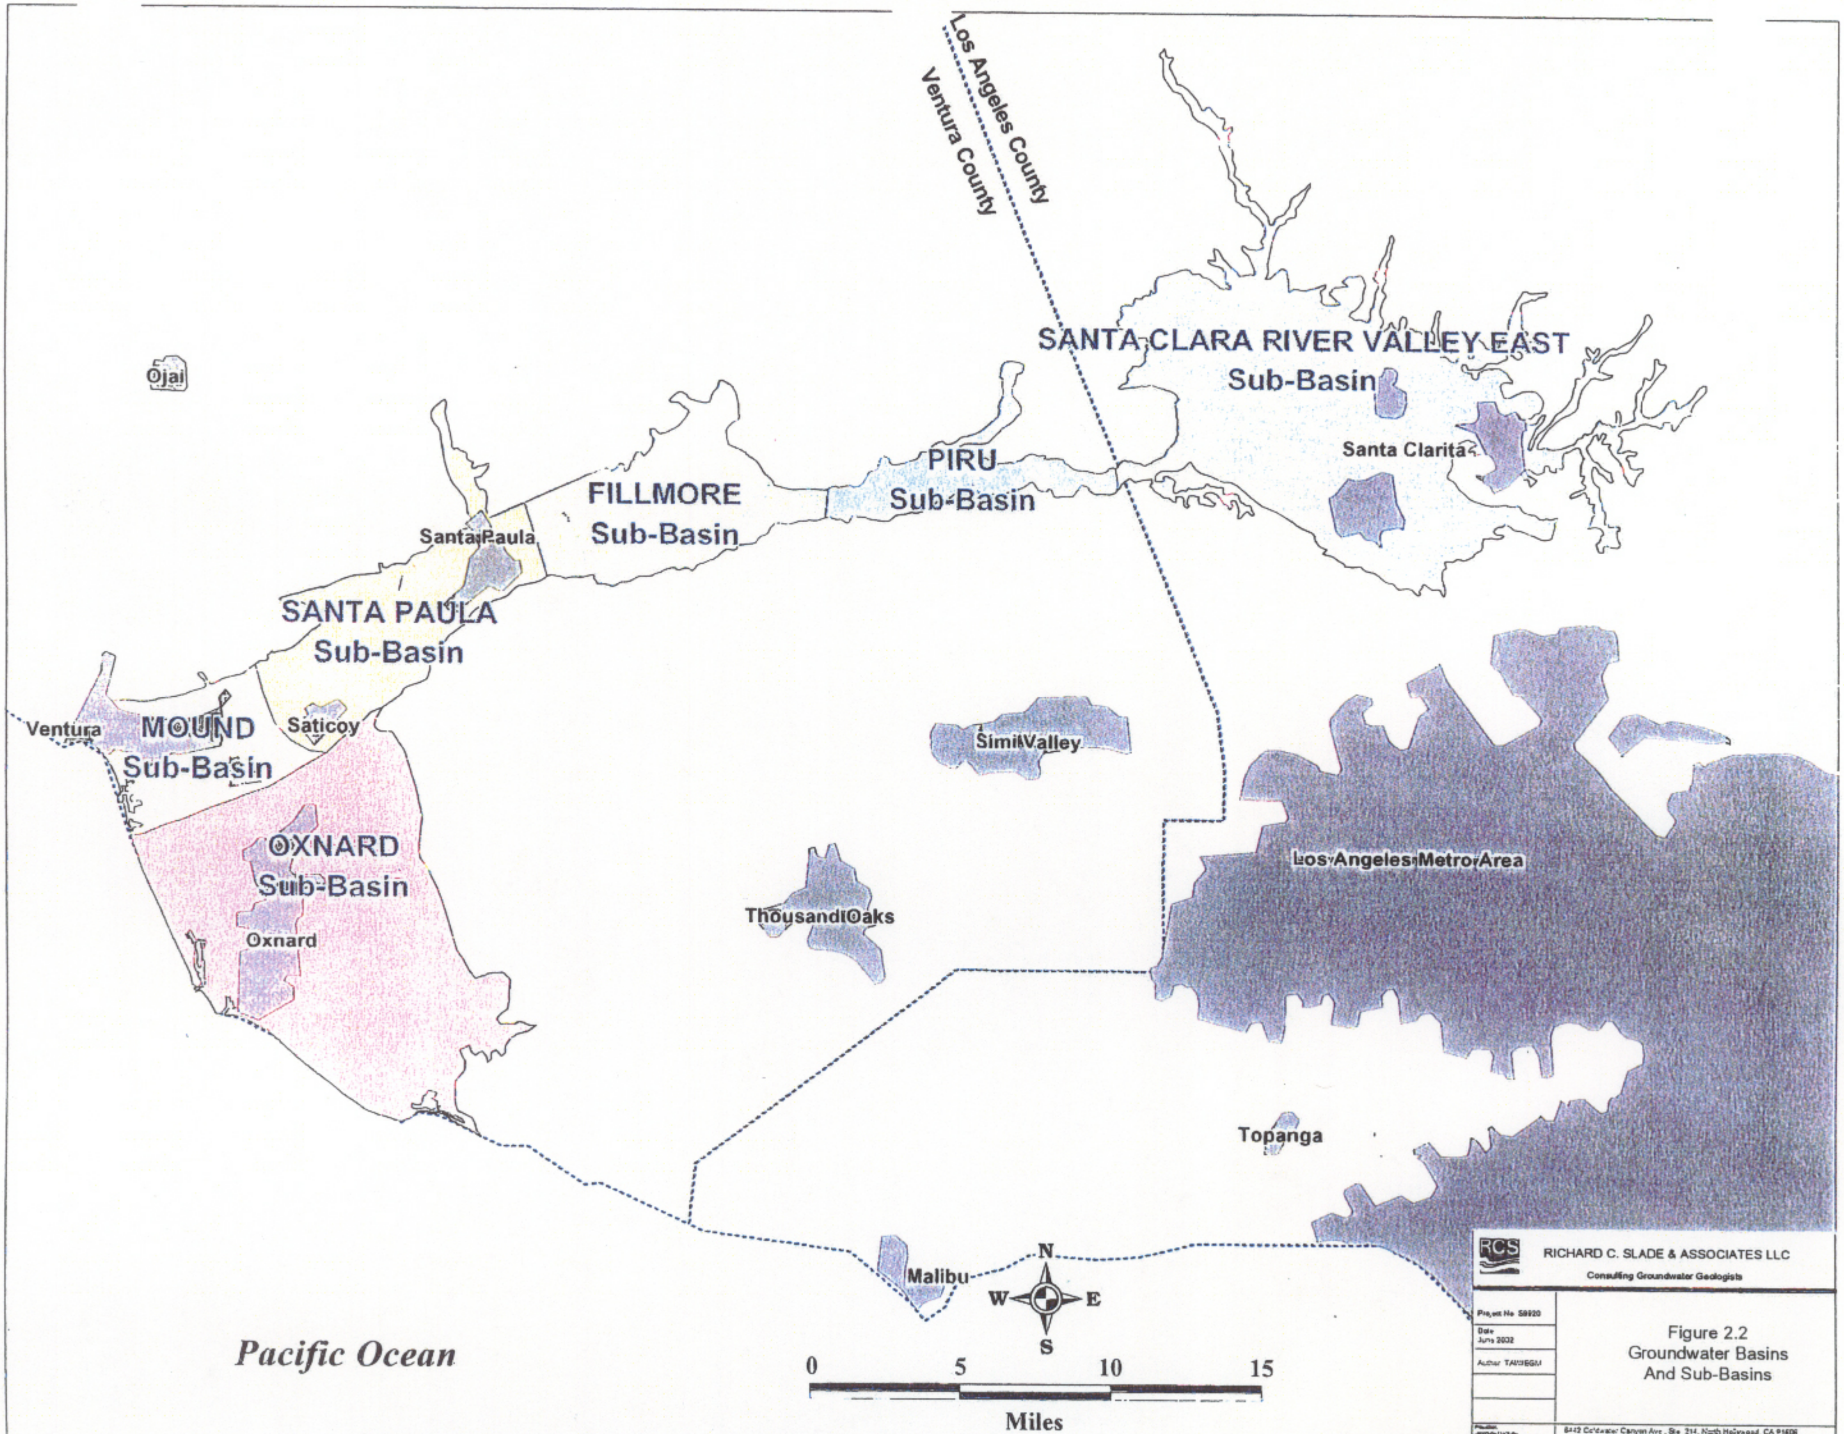

Figure 2.2
Groundwater Basins
And Sub-Basins

system of the Santa Clara River at County line; surface water outflow to Ventura County occurs only via direct surface runoff in the Santa Clara River at County line (see Figure 2.2).

SECTION 3

SUMMARY OF GEOLOGIC CONDITIONS

General Statement

Geologic materials illustrated on Plate 3.1 – Geologic Map of the Santa Clarita Valley - have been divided according to their relative water-bearing characteristics, that is, by their relative ability to contain, transmit, and yield groundwater to wells. As such, two divisions are recognized in the Valley: a water-bearing sediment group and a non-water-bearing bedrock group.

The water-bearing sediments consist of a blanket of unconsolidated alluvium of Quaternary geologic age (map symbol, Qal) that covers the floor of the main river valley and its tributary canyons, and the consolidated sediments of the slightly geologically older Saugus Formation (Pliocene to Pleistocene geologic age; map symbol, QTs) which underlie the alluvium. Scattered outcrops of Quaternary-age Terrace deposits (map symbol, Qt) likely have the capacity to contain limited amounts of groundwater on a seasonal basis, but these deposits crop out in only limited areas that are typically situated at elevations above the regional water table.

The alluvium and the Saugus Formation have been penetrated to various depths by numerous water wells and have historically provided all the groundwater extracted in the Valley for municipal-supply purposes. Underlying the water-bearing sediments and exposed on the hillsides beyond the limits of the Saugus Formation exposures are the various older geologic formations that comprise the relatively impermeable, non water-bearing bedrock.

Water-Bearing Sediments

Alluvial Deposits

Sediments shown on Plate 3.1 as Quaternary alluvium range in geologic age from Quaternary to Holocene (Recent), and consist primarily of stream channel and floodplain deposits of the Santa Clara River and its tributaries. Geologic logging performed by RCS geologists during recent water well drilling activities, and an analysis of drillers' logs of older water wells, reveals that the alluvial sediments are composed of complexly interlayered and interfingered beds of gravel, sand, silt, and clay, with variable amounts of cobbles and boulders. In general, alluvium along the main reach of the Santa Clara River ranges from cobbly- or gravelly-sand in the east, to medium-grained sand in the west. Due to its unconsolidated to poorly consolidated nature and its lack of cementation, the alluvium is considered to have relatively high permeability and porosity.

The maximum thickness of alluvium varies along the Santa Clara River, but generally is considered to be about 200 feet along the main reach of the river. Typically, the alluvium tends to be thickest near the central portion of the main river channel, but then thins or pinches out near the base of the adjoining hills.

Geologic logging of the pilot boreholes for municipal-supply water wells constructed in recent years within the alluvium along the main reach of the Santa Clara River reveals that the alluvium has maximum depths of approximately: 114 ft at SCWC Mitchell Well No. 5B (drilled in 2001); 155 ft in SCWC Lost Canyon Well No. 2A (drilled in 1989); 160 ft in VWC Well W-10 (drilled in 2001); and from 180 ft to 200 ft in VWC Wells S-6, S-7 and S-8 (drilled in 1999 to 2000). Locations of these alluvial wells are shown on Plate 4.1 in Section 4 of this report.

Alluvium in the tributary canyons is generally thinner than that along the main river valley. Larger tributary canyons such as Castaic Creek, San Francisquito Canyon and Bouquet Canyon are typically underlain by more laterally extensive and thicker accumulations of alluvium than which exist within the smaller canyons like Oak Spring or Pico canyons. In these latter canyons, the maximum alluvial thickness occurs near the confluence with the main river valley and is considered to be on the order of 100 feet.

Only two active municipal-supply alluvial wells (VWC W-9 and W-10) have been constructed in recent years in any of the major tributaries of the Santa Clara River. Well W-9 was drilled in 1990 in San Francisquito Canyon, approximately 7000 ft north of its confluence with the main reach of the Santa Clara River (see Plate 4.1). Geologic logging of the pilot hole for this well revealed that the alluvium has a maximum thickness of approximately 140 ft at this location. VWC Well W-10 was drilled in 2001 near the confluence of San Francisquito

Canyon and the Santa Clara River (see Plate 4.1). At this location, the alluvium was geologically logged to a depth of 160 ft.

Another well (now destroyed) was drilled in 1990 along San Francisquito Canyon (VWC No. 202, a Saugus Formation well), approximately 9500 ft north of its confluence with the Santa Clara River (see well location on Plate 5.1 in Section 5 of this report). Geologic logging of the pilot hole for this well revealed the alluvium to be approximately 50 ft thick at this location.

The approximate thickness of alluvium logged in the borehole for a new alluvial groundwater monitoring well in the South Fork area is 190 ft. This monitoring well was constructed in 2000, approximately 40 ft south of VWC 201, as part of the assessment of the feasibility for an aquifer storage and recovery (ASR) program in the Saugus Formation (Slade and Associates LLC, February 2001).

Geologic logging of the pilot boreholes for Saugus Formation water wells drilled since the Slade 1988 Report, and/or correlation of electric logs for existing Saugus Formation wells, reveal the following information on the approximate maximum thickness of the alluvial deposits at these sites (see well locations on Plate 5.1):

a. South Fork area: approximately 80 ft in NCWD-13; 120 ft in NCWD-12; 170 ft in Saugus Well No. 1; and in the range of 150 ft to 180 ft in SCWC Saugus Well No. 2.

b. Main Reach Santa Clara River: less than 50 ft at V-205; 120 ft at V-158; 190 ft at V-157 and V-201; 220 ft at V-203; and approximately 240 ft at V-160.

Terrace Deposits

Terrace deposits are isolated remnants of what was, during the late Pleistocene, a continuous blanket of alluvial material covering the entire floor of the Santa Clara River Valley (Winterer and Durham, 1962). Tectonic uplift of the valley floor led to downcutting and incision of this geologically older alluvial material by the Santa Clara River, leaving the terrace deposits restricted to platforms or benches that are now topographically higher than the Santa Clara River, and hence above the regional water table. Sediments comprising the terrace deposits include crudely stratified, poorly consolidated reddish-brown gravel, sand and silt (Winterer and Durham, 1962). Terrace deposits may be weakly cemented by iron oxides, clay minerals, or calcium carbonate. Plate 3.1 illustrates the locations of the surface exposures of terrace deposits in the Valley as mapped by others.

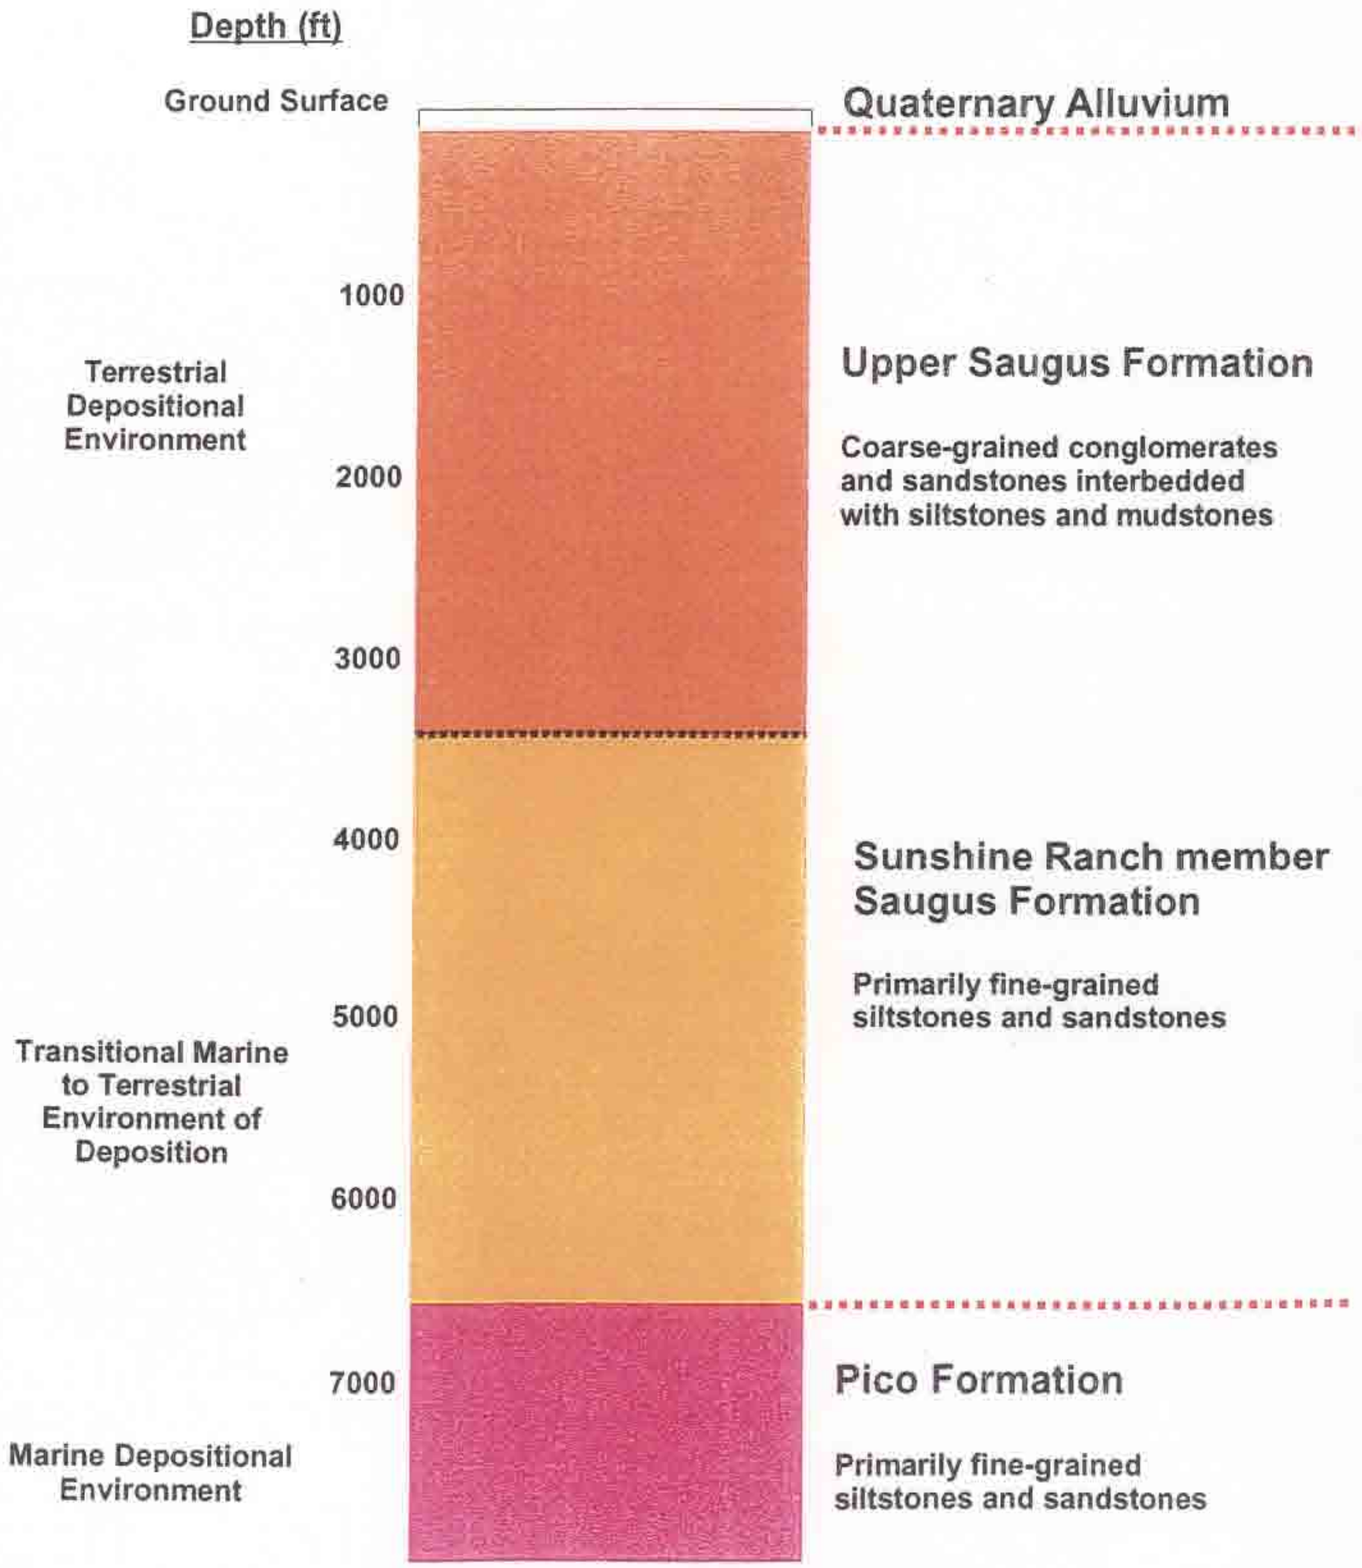
Terrace deposits reportedly may be up to 200 ft thick in some areas, but because they are of limited areal extent and because they are generally above the regional water table, they are not considered a viable source for the development of groundwater resources. However, limited zones of perched groundwater may be locally present in portions of these terrace deposits on a seasonal basis. No wells in the Valley have ever been known to extract groundwater from these terrace deposits.

Saugus Formation

The Saugus Formation has traditionally been divided into two stratigraphic units: the lowermost, geologically older Sunshine Ranch Member which is of mixed marine to terrestrial origin; and the remaining, overlying or upper portion of the formation which is entirely terrestrial (non-marine) in origin (Winterer & Durham, 1962); refer to Figure 3.1 – Saugus Formation Stratigraphy – for details of the stratigraphy. The Saugus Formation has been assigned a Pliocene to Pleistocene geologic age based on rare fossil occurrences (Winterer and Durham, 1962).

South of the San Gabriel fault, the gradational contact between the Sunshine Ranch Member and the underlying, geologically older Pico Formation represents a gradual transition from a marine to a continental (terrestrial) environment of deposition throughout the entire study area. Because of its gradational nature, the location of this contact is sometimes difficult to accurately identify, either visually in the field or from e-log correlations.

The Sunshine Ranch Member of the Saugus Formation comprises interfingering shallow marine, brackish-water, and nonmarine deposits of interbedded gray to greenish-gray sandstone and siltstone. Fossils found within the Sunshine Ranch Member indicate an upper Pliocene geologic age for this part of the Saugus Formation. The Sunshine Ranch Member obtains a maximum thickness of approximately 3,500 ft in the central part of the Valley.



RICHARD C. SLADE & ASSOCIATES LLC
CONSULTING GROUNDWATER GEOLOGISTS

FIGURE 3.1
Saugus Formation Stratigraphy

JOB NO. S9920 June 2002

Because of the marine origin and the fine-grained nature of the Sunshine Ranch Member, it is not considered to be a viable target for groundwater exploration or production for municipal-supply purposes. Wells drilled near the periphery of the surface exposures of the Saugus Formation, that is, where the Sunshine Ranch Member is at or very close to ground surface, have typically produced groundwater at rates too low for municipal-supply purposes. Evidence from e-logs also suggests that the groundwater in much of the Sunshine Ranch Member may be somewhat brackish in quality and, hence, not useful for municipal-supply purposes.

Stratigraphically above the Sunshine Ranch Member, the Saugus Formation becomes coarser-grained, consisting mainly of lenticular beds of light-gray and brown sandstone and conglomerate that are interbedded with lesser amounts of reddish-brown sandy mudstone. These terrestrial sediments were deposited in stream channels, floodplains and alluvial fans by one or more ancestral drainage systems in the Valley area. The coarser-grained sand and gravel beds of the Saugus Formation were deposited in the main channels of the ancient drainage systems, and these more permeable beds constitute the potential aquifers within the present-day Saugus Formation that will be discussed in this report. As the locations of the ancestral drainage channels changed during the approximately 3 million-year period of deposition of the Saugus strata, the distribution of the coarse-grained channel deposits also changed, both laterally and vertically (in space and time).

The coarse-grained potential sand and gravel aquifers of the Saugus Formation can be distinguished from the finer grained silt and clay layers (i.e., the aquicludes or aquitards) on the basis of their respective electric log signatures. From our analysis of these e-logs, it is evident that the coarse-grained channel deposits (the potential water-bearing strata) are thicker and more numerous in some areas of the Valley than in others. The general distribution of sand and gravel units in the upper portion of the Saugus Formation (between the depths of 300 ft and 2500 ft below ground surface or bgs) can be seen on Plate 3.2 – Thickness of Potential Sand and Gravel Aquifer Units. Details on how that map was constructed are provided in Section 5 of this report.

Although the Saugus Formation displays a considerable amount of lateral variability in lithology and grain size, some thicker stratigraphic packages can be correlated throughout large parts of the local groundwater sub-basin, as can be seen on Plate 3.3 – Geologic Cross-Section Z-Z'. These correlations were produced by identifying distinctive marker horizons during a detailed evaluation of e-logs from approximately 170 oil wells and water wells across the groundwater sub-basin. The locations of this new cross-section that is presented herein and of those presented in the Slade 1988 Report (not reproduced herein), are shown on Plate 5.1 in Section 5 of this report.

One of these key correlated stratigraphic units identified on Plate 3.3 is informally designated herein as the Santa Clarita Aquifer Zone. This unit is not present everywhere in the local groundwater sub-basin, and where it is present, it occurs at different depths below ground surface. Plate 3.4 – Map of Top of Santa Clarita Aquifer Zone – illustrates these variations in the depth to this key stratigraphic unit based on e-log correlations.

It is noteworthy that existing Saugus Formation wells, depending on location, produce groundwater from Saugus Formation strata that lie both above and below the Santa Clarita Aquifer Zone. However, there is a general trend for wells that are screened within or stratigraphically above the Santa Clarita Aquifer Zone to have higher groundwater production rates. Figure 3.2 – Type Electric Log and Santa Clarita Aquifer Zone, VWC 205M – shows a typical e-log (i.e. the "type e-log") for the Saugus Formation from VWC 205M, the 1956-foot deep Saugus Formation groundwater monitoring well that lies approximately 35 ft from VWC 205. Shown on this type e-log is the top of the Santa Clarita Aquifer Zone. Geologically, this Santa Clarita Aquifer Zone lies stratigraphically within the younger (upper) portion of the Saugus Formation in the region.

Non Water-Bearing Bedrock

The Saugus Formation, and in places the overlying Quaternary alluvium, overlie several older, non-water bearing formations in the region. Along the southern and western part of the study area, the Saugus Formation conformably and gradationally overlies the Pico Formation, an older unit of marine origin consisting of gray siltstone and fine-grained sandstone, and light-colored sandstone and conglomerate. The finer-grained portions of the

JOB NO. S9920 June 2002

Pico Formation predominate in the western part of the Valley, whereas in the eastern part, the formation consists mainly of sandstone and conglomerate (Winterer & Durham, 1962). Quaternary alluvium lies directly on Pico Formation rocks in the area west of the Saugus Formation boundary (refer to Plate 3.1).

In the extreme southeastern portion of its outcrop area, the Saugus Formation lies directly and unconformably on much older (pre-Tertiary geologic age) igneous and metamorphic rocks of the San Gabriel Mountains (refer to Plate 3.1). North of the San Gabriel fault, the Saugus Formation unconformably overlies Miocene-age terrestrial sediments of the Tick Canyon and Mint Canyon formations (refer to Plate 3.1). Quaternary alluvium also lies directly on Mint Canyon Formation rocks in the area east of the Saugus Formation boundary.

These older formations that underlie the water-bearing alluvium and Saugus Formation tend to be well-consolidated and cemented, with relatively low porosity and permeability. Wells and test holes drilled in these rocks have typically encountered low groundwater production rates and sometimes groundwater of relatively poor water quality. These older rocks, which essentially form the bedrock to the alluvium and Saugus Formation within the Valley, are not considered water-bearing in terms of their ability to supply groundwater in useable quantities and of acceptable quality for municipal-supply purposes.

Geologic Structure

The Quaternary alluvium is essentially undeformed by recent tectonic activity such as folding or faulting. To some extent, this is also true for the terrace deposits, although they have been tectonically uplifted and in some areas are slightly folded. One such fold has been mapped where the terrace deposits crop out in the hills east of San Fernando Road and the South Fork of the Santa Clara River.

The general structure of the underlying Saugus Formation is one of an isolated "bowl" that has been cut (at least in part) by two major faults and that has also folded along a number of east-west trending folds. The sedimentary layering in the Saugus Formation is inclined (dips) generally toward the center of the "bowl" from all locations along the outer (basal) contact of the Saugus Formation with the underlying formations.

The San Gabriel and Holser faults divide the outcrop area of the Saugus Formation into three structural blocks (refer to Plate 3.1). The San Gabriel fault is primarily a northeast-dipping reverse fault, with a small (less than 500 ft) component of right-lateral, post-Saugus Formation offset (Weber, 1982). The structural block north of the San Gabriel fault has been uplifted relative to the rest of the Valley, and consequently the Saugus Formation in this area is considerably thinner than elsewhere in the Valley. In addition, the Saugus Formation that remains north of the San Gabriel fault consists entirely of the lowermost Sunshine Ranch Member (see Figure 3.1). All overlying, younger and coarser-grained portions of the Saugus Formation have been removed by erosion in this area north of the San Gabriel fault.

The Holser fault is also primarily a reverse fault and the structural block south of this fault has also been uplifted relative to the rest of the Valley; this fault is considered to dip towards the southwest. However, the amount of uplift is considerably less than in the area north of the San Gabriel fault, and a substantial thickness of upper Saugus Formation sediments remains in the southern structural block (south of the Holser fault).

Work by Stitt and Yeats (1983) has cast some doubt on whether a portion of the Holser fault actually extends east of I-5 underneath the blanket of Quaternary alluvium, and whether or not the short fault strand which splays off of the San Gabriel fault in the hills just east of San Fernando Road is part of the Holser fault. Although our in-house e-log correlations do show some apparent offset of strata across the presumed subsurface trace of this fault, the offset could also be explained by dipping beds. In any case, the Holser fault does not appear to have a significant effect on groundwater availability or movement within the Saugus Formation.

The thickest part of the Saugus Formation occurs in the central structural block, bounded by the San Gabriel fault on its north side, and the Holser fault on its south side. This central block has not been uplifted and hence the upper, coarser-grained portions of the Saugus Formation rocks have been largely protected from erosion in this central block area.

SECTION 4

HYDROGEOLOGIC CONDITIONS IN THE ALLUVIAL AQUIFER SYSTEM

Water Wells

Available records reveal that several hundred water wells have been historically drilled in the Valley for domestic, agricultural, industrial, or municipal usage. Nearly all of these wells have been drilled within the areas of alluvial deposits along the Santa Clarita River and its tributaries. Most of these wells are less than 200 ft in depth and likely extract groundwater primarily from the alluvial sediments (Slade 1988 Report).

This section focuses on the relatively high-production municipal- and agricultural- supply alluvial wells in the Valley (refer to Plate 4.1 – Map of Alluvial Well Locations; and Table 4.1 – Construction Data for Existing Alluvial Wells). Municipal-supply wells extracting groundwater from the alluvial sediments in the Valley are owned and operated by: VWC (16 active wells); NCWD (7 active wells); and SCWC (12 active wells). In addition, the Los Angeles County Sheriffs Department has a number of alluvial wells in the Castaic Creek area that supply groundwater to the detention facilities within the WHR complex. However, only three of these wells are reportedly in active use. Further, NLF reportedly has approximately 24 currently active irrigation-supply alluvial wells, most of which are located in the western end of the Valley (west of I-5). Finally, CLWA owns an alluvial well (known as the Park well) near its headquarter facilities and operates it for irrigation-supply purposes (see Plate 4.1); construction data are not available for this well.

New Wells

Between the publication of the Slade 1986 Report and 2000, more recent information reveals that 13 additional municipal- and agricultural-supply alluvial water wells have been constructed in the Valley by the water purveyors and by the WHR (refer to Plate 4.1 for locations). These new wells include: 2 wells constructed for SCWC (Lost Canyon 2A in 1989 and the Mitchell 5B in 2001); 5 wells constructed for VWC in 1990 (W9) and in 1999-2001 (S6, S7, S8, W10); and 6 wells constructed for WHR in the late-1980s (Nos. 1, 2, 3 and 4)

and in 1999 (New No. 11 and New No. 18). Construction data are available for the new SCWC and VWC wells; similar information for the WHR wells was not available for this study.

Destroyed Wells

A number of older municipal- and agricultural-supply alluvial water wells have been destroyed between 1987 and 2000 (refer to Table 4.2 – Destroyed Alluvial Wells). These include NLF Wells E3, E7, Q, R, R2, S, S2, S3, and T. Each of these wells was reportedly destroyed in accordance with the regulations of the Los Angeles County Department of Health Services to minimize the possibility of surface contaminants migrating into the alluvial aquifer via the well bore. Two WHR Wells (Old Nos. 11 and 18) were also destroyed relatively recently, but no details on these well destructions were available for this study.

Private Wells

With a few exceptions, discussion of privately-owned water wells that are used for local domestic supply lies outside the scope of this study; the locations for these wells are not shown on any plates for this report. Although such private wells may be numerous, most of them are considered to be small, low-capacity wells, and the total annual groundwater extraction by these domestic-supply wells is considered to account for only about 1% of the alluvial groundwater production in the Valley.

The Robinson Ranch well is a new privately-owned alluvial-supply well reportedly constructed along the Santa Clara River to provide irrigation water to two new golf course developments in the hillsides south of the general area of NCWD's Pinetree wells in the easternmost part of the alluvium. No details on its construction were available for this study. Plate 4.1 illustrates the approximate location of this well.

Groundwater Occurrence, Recharge and Discharge

Within the saturated zone of the unconsolidated alluvial sediments, groundwater is present in the pore spaces between individual sedimentary grains. These alluvial sediments were deposited primarily by flowing streams and rivers that precluded the formation of areally extensive beds or layers of fine-grained silts and clays. Because of this, groundwater in the

Table 4.2

alluvium is considered to occur under unconfined (water table), conditions, although some localized zones of perched water may locally exist in certain tributary canyons or along the main reach of the Santa Clara River.

Recharge

Groundwater in the alluvial aquifer system is recharged from both natural and artificial (man-made) sources. Sources of natural recharge include deep percolation of precipitation that falls directly on the alluvial deposits, subsurface groundwater inflow from upstream areas along the Santa Clara River or its tributaries, upward groundwater flow from certain portions of the Saugus Formation where it is overlain by alluvium, and direct infiltration from surface water runoff along the Santa Clara River and its tributaries.

CH2M Hill recently examined recharge and discharge to the alluvial aquifer system as part of an ASR study (Newhall Ranch ASR Impact Evaluation, 2001). That study found that recharge to and discharge from the alluvium does not occur evenly across the area, but is focused in particular areas. Specifically, their work shows that the largest source of recharge to the alluvium is likely upward flow of groundwater from the underlying Saugus Formation, with this recharge occurring primarily in the downstream portion of the alluvium located generally west of I-5. The CH2M Hill work also indicates that deep percolation of groundwater from the alluvium occurs downward into the Saugus Formation in the upstream portions of the alluvium located in the central and eastern portions of the Valley.

Recharge to the alluvial aquifer system via infiltration of surface water runoff from the Santa Clara River will occur whenever and wherever groundwater levels in the aquifer are below the surface elevation of the river runoff. Using historic data on alluvial water levels, as well as data from several stream flow gages along the Santa Clara River and its tributaries, CH2M Hill determined that the alluvial aquifer system is being recharged from the Santa Clara River in the area upstream from the confluence with the South Fork of the Santa Clara River (CH2M Hill, 2001). In this area, the Santa Clara River is ephemeral, that is, it flows only in the hours or days immediately following significant winter rainfall events. Recharge will occur only while the river is actually flowing, and the amount of recharge will depend largely on the duration of each surface flow event, and, in some parts of the aquifer, on water levels within the alluvial aquifer.

The amount of recharge obtained by the alluvial aquifer from the direct percolation of precipitation will vary each year depending on such conditions as the amount and timing of rainfall, local soil type, and land use characteristics. Finally, natural recharge by inflow from upstream areas will depend on the cross-sectional area of the saturated alluvium at the upstream end of the study area, on the hydraulic conductivity of the alluvial materials, and on the gradient of the alluvial water table.

Recharge from deep percolation of irrigation water is obtained primarily from urban irrigation (landscape irrigation) in the developed areas of the Valley. Agricultural irrigation was previously more widespread in the Valley, but is now confined mainly to approximately 700 acres of cultivated land in the area west of I-5. Recharge also occurs indirectly as a result of the infiltration of reclaimed water that is actively being released to the Santa Clara River from the two WRPs in the area.

While artificial recharge of the alluvium via spreading basins or other means was discussed in the Slade 1986 Report, there are currently no artificial recharge facilities operating within the study area.

Discharge

Except for groundwater outflow directly from the alluvium down into the underlying Saugus Formation or upward to the Santa Clara River, discharge from the alluvial aquifer system occurs primarily through pumping extraction for municipal-supply use by the water purveyors, and for agricultural-supply use by NLF. Historic annual extractions by these organizations have varied between 20,000 and 43,000 AF/yr during the period for which data are available (1947 to the present).

Evapotranspiration by phreatophyte vegetation is also an important component of the discharge of groundwater from the alluvium. Phreatophytes are plants such as willows and cottonwoods that root directly into the water table in areas of shallow groundwater. CH2M Hill (2001) estimated that as much as 8 to 12% of the total groundwater discharge from the alluvium occurs in this way, primarily in those alluvial areas west of I-5 where depths to groundwater are relatively shallow.

This westernmost part of the local groundwater sub-basin is also an area of groundwater discharge from the alluvium to the Santa Clara River. The amount of upward flow into the river will depend largely on water levels within the alluvium. Groundwater also flows out of the Valley into Ventura County, but this occurs solely as subsurface flow within the alluvium at the downstream end of the study area (the Los Angeles/Ventura County Line). The only other water to flow from the Valley into Ventura County is via direct surface water runoff in the Santa Clara River at County line.

Groundwater Extractions

Groundwater production from the alluvial aquifer system is used primarily for municipal-supply and agricultural-supply purposes. Because of the large number of alluvial wells that have existed since the 1950s, and the difficulty in obtaining groundwater production data for these wells, the groundwater production values discussed in this section can only be viewed as reasonable estimates, particularly for the period prior to 1985.

Figure 4.1 - Historic Alluvial Groundwater Production – illustrates, as a bar chart, the historic trends in alluvial groundwater production since the mid-1940s, the earliest date for which any production records are available. Since that time, total alluvial groundwater production has ranged from a low of approximately 20,000 AF/yr in 1983, to a high of at least 44,000 AF/yr in 1955. For the ten-year period from 1991 to 2000, the average annual alluvial groundwater production by the major producers was approximately 35,000 AF/yr. The historically largest groundwater periods of production from the alluvium occurred between 1951 and 1960, and between 1991 and 2000 (both 10-year periods), during which time the average extractions were approximately 37,000 AF/yr and 35,000 AF/yr respectively. Between those two periods, the region has experienced a dramatic land use change from mainly agricultural to mainly urban and suburban land use. Table 4.3 – Alluvial Groundwater Production 1986 – 2000 – provides a tabulation of groundwater production by each major producer for the period 1986 through 2000.

Note: Production figures from Wayside Honor Ranch are estimates based on total prison estimate populations.
All of the data is supplied by purveyors. Figures do not include domestic or other small-scale extractions.

Groundwater production from the alluvial aquifer system is distributed along the main reach of the Santa Clara River, in the Castaic Creek drainage, and in several of the tributary canyons. Thirteen municipal-supply water wells in the alluvial aquifer system each produced in excess of 1000 AF in 2000 as shown on Table 4.3.

Between 1986 and 2000, NCWD accounted for between 4% and 12% of the total annual alluvial groundwater production; VWC produced between 18% and 31% of the total annual production; SCWC extracted between 26% and 46% of the total annual production; NLF pumped between 25% and 35% of the total annual production; and WHR reportedly accounted for between 8% and 9% of the annual production in this period from the alluvium.

Annual production from the privately-owned, domestic-supply alluvial wells is not known, but is unlikely to have exceeded a total of 100 to 200 AF/yr for all privately-owned, domestic-supply alluvial wells in the region. This represents only about 1% of the average annual groundwater production since 1986 from the alluvium. Beginning in 2000, a new privately-owned golf course irrigation well along the Santa Clara River east of Sand Canyon became active. Although metered pumpage figures are not available for this new well, it is estimated that this well might extract on the order of 350 AF/yr for each of the two onsite 18-hole golf courses that it irrigates.

To illustrate the spatial variability in recent alluvial groundwater extractions within the Valley, we have prepared Plate 4.2 – Map of Alluvial Groundwater Extractions for 2000. Data for Plate 4.2 were derived from the information tabulated for the year 2000 on Table 4.3 for each active municipal-supply well. Annual groundwater extractions for each well on Plate 4.2 are illustrated via a circle centered on the respective well. The larger the diameter of the circle, the greater is the extraction for the particular well in 2000. The map scale used to illustrate the diameter of the circle which represents the year 2000 annual production is: 1 inch equals approximately 667 AF (or, ¾" = 500 AF). It must be noted that the circles (specifically, the diameter of the circles) graphed on Plate 4.2 are drawn to solely represent the relative annual production volume (in AF) for each respective well. The diameter of the circle surrounding each well does not represent and should not be construed or interpreted to signify the area of pumping influence (the extent of the drawdown cone) of the particular well.

For 2000, the largest municipal-supply alluvial extractions occurred along the main reach of the Santa Clara River, by SCWC (in areas east of Bouquet Junction) and by VWC (near and just west of Bouquet Junction); WHR extractions were the largest in Castaic Creek, north of its confluence with the Santa Clara River. There are no municipal-supply wells within the alluvium in the South Fork area of the Santa Clara River or along the main reach of the river valley west of I-5.

Current Groundwater Levels and Flow Directions

Groundwater levels and flow directions within the alluvial aquifer system were determined by creating contour lines of equal groundwater elevation (in ft above sea level, asl) for the available data from wells within the alluvial sediments in the study area. The data used to create these contour lines consisted of measurements, in numerous individual alluvial wells, of the depth to the static (non-pumping) water level. These depths were converted to elevations by subtracting the depth from the reported ground surface elevation at each wellhead. Groundwater flow directions were then determined by recognizing that groundwater flows from high head to low head; hence, the general direction of groundwater flow within the alluvial sediments is interpreted to be perpendicular to the equal elevation contour lines for the date depicted.

Plate 4.3 – Map of Alluvial Groundwater Elevation Contours, Spring 2000 – illustrates the groundwater elevations and interpreted flow directions for the spring (March to May) of 2000, a recent period for which widespread water level data are available. Water level data from approximately 100 different wells throughout the Valley were used to create the elevation contours, with data being obtained from the municipal water purveyors, agricultural well owners, the LACFCD database, and reports on water levels in piezometer wells provided by Seward Engineering Ltd (SE).

As illustrated by the broad arrows on Plate 4.3, groundwater flow directions within the alluvial aquifer system generally mimic surface water flow directions and the land surface gradient, with groundwater moving from east to west along the main reach of the Santa Clara River, and from highland areas towards the main river valley within the alluvium in the tributary canyons along each side of the valley floor. In the main river valley, groundwater elevations decline from a high of approximately 1700 ft above sea level (asl) in the eastern end of the study area, to a low of about 820 ft near the Los Angeles-Ventura County Line in the west (see Plate 4.3). This equates to a decline of approximately 880 ft over a distance (paralleling the Santa Clara River) of 22 miles, and calculates to an overall down-valley gradient of approximately 40 feet per mile (ft/mi).

The gradient is steeper in the eastern portion of the main Valley east of Bouquet Canyon, where the water level drops 325 ft in 5.6 miles; this represents a gradient of roughly 58 ft/mile. This compares with a gradient of 50 ft/mi for the same area calculated from 1985 water levels (Slade 1986 Report).

In the western part of the alluvium between Bouquet Canyon and the County Line, the groundwater elevation drops 555 ft over 16.3 miles, representing a gradient of roughly 34 ft/mi. This compares with a gradient of 31 ft/mi calculated from 1985 water levels (Slade 1986 Report).

Groundwater gradients are much steeper in the major tributary canyons for which sufficient data exist, with measured spring 2000 gradients of approximately 90 ft/mi in Mint Canyon, 56 ft/mi in Bouquet Canyon, 42 ft/mi in San Francisquito Canyon, and 31 ft/mi along Castaic Creek. The well monitored by LACFCD in the baseball park along Bouquet Canyon appears to be the Park well owned by CLWA; its LACFCD well number is likely 7086B (see Plate 4.2).

An interesting feature on Plate 4.3 is the very low groundwater gradient within the alluvium along the South Fork of the Santa Clara River, a feature that was also seen on previously prepared groundwater elevation maps of the alluvium (Slade 1986 Report). The average gradient along the South Fork for Spring 2000 data is only on the order of 13 ft/mi, although a detailed delineation of gradients in this area is made difficult by the virtual absence of requisite data from alluvial wells in this area. However, it does not appear that any "up-valley" or reversed groundwater flow is occurring southward into this South Fork area.

There is no evidence from the available data that either the San Gabriel or the Holser faults acts as a barrier to groundwater flow within the alluvial deposits of the Santa Clara River or its tributaries.

Hydrographs

For the purpose of examining long-term water level trends within the alluvial aquifer, the Valley can be divided up into three areas: the western area, between the Los Angeles/Ventura County line and I-5; the central area, between I-5 and the mouth of Bouquet Canyon; and the eastern area, from Bouquet Canyon east to NCWD Pinetree Well No. 1, which is the easternmost municipal-supply well in the alluvial aquifer system. Long-term water level trends in selected alluvial wells are presented in the form of hydrographs which are graphs of the static water levels (i.e., the non-pumping water levels) in the well versus time; also provided on each hydrograph is a portion of the cumulative departure curve for rainfall (for the period 1950 to 2000) as adapted from Figure 2.1.

The hydrograph for NLF Well C8 (Figure 4.2 – Hydrograph of NLF Well C8: see well location on Plate 4.3 – Map of Alluvial Well Hydrographs) provides a useful, long-term record of water levels in this western part of the alluvial aquifer system (i.e., in the alluvium west of I-5). Water levels in this area have remained remarkably constant over time as evidenced by data for this well, ranging from a high of approximately 13 ft bgs, to a low of 37 ft bgs over a period of data record of approximately 50 years. This lack of marked water level fluctuation in this well is likely due to the well being located in an area where groundwater from the Saugus Formation is considered to be flowing upward into the overlying alluvium, thereby providing a fairly consistent source of recharge that is relatively independent of annual rainfall trends. There has also been somewhat less year-to-year variability in water levels in this well over the past twenty years, when compared to the variability seen in the same record from the 1950s through the 1970s. This may in part be due to the increased additional recharge to the alluvium provided by increasing outflows from the two WRPs located upgradient from this well. Total WRP discharges were approximately 19,000 AF in 2000.

In the central portion of the alluvium, in the area near the confluence of the South Fork with the main reach of the Santa Clara River, the hydrograph for VWC Well Q2 (Figure 4.3 – Hydrograph of VWC Well Q2: see also Plate 4.3 for well location) shows the typical water level response in this area over time. During the 1950s and 1960s, a time of high alluvial

groundwater production and low rainfall, water levels in this well averaged approximately 70 to 75 ft bgs, within an historic range of 42 to 98 ft bgs. Reduced pumping in the alluvium, and a return to more normal rainfall patterns in the 1970s and 1980s, resulted in a rapid recovery of water levels to depths of between 6 and 27 ft bgs; water level declines were to depths as much as 51 ft bgs during the dry years of the mid-1970s. A return to the higher rates of annual alluvial groundwater extractions in the 1990s did not result in a return to the low water levels typical of the 1950s and 1960s. This in part is due to the generally normal rainfall patterns over the last ten years, and the increased recharge provided to the alluvium from the two local WRPs.

Finally, in the eastern portion of the alluvial aquifer, the representative hydrograph for the SCWC Mitchell Well 5A (Figure 4.4 – Hydrograph of SCWC Mitchell Well 5A and also Plate 4.4) shows a much stronger correlation with annual rainfall totals than is shown by the hydrographs for wells in either the central or western parts of the Valley. Water levels in these easterly-area wells during wet periods such as from 1978 to 1983 tend be in the range of 10 to 20 ft bgs, falling to as low as 101 ft bgs during periods of extended drought such as that from 1984 to 1991. However, by 1993, after a return to wetter climatic conditions, water levels recovered rapidly to their pre-drought range. Water levels also show a declining response during the dry years of 1996 to 1997, and 1999 to 2000. From past trends, it can be seen that these lower water levels are a temporary condition, which then (regardless of the total alluvial production) rapidly return to higher water level conditions as soon as wetter conditions prevail.

Differences in the response of water levels over time in wells located in different parts of the alluvial aquifer system in the Valley are readily seen on Plate 4.4. Hydrographs shown thereon are for various municipal-supply wells, an irrigation-supply well, and for a few LACFCD-monitored wells that are privately-owned (see for example LACFCD Well No. 7132 in the northern portion of Bouquet Canyon).

Aquifer Parameters

The Slade 1986 Report presented a map of estimated aquifer parameters calculated from efficiency tests conducted in a number of alluvial water wells in the Valley by the Edison

Company. Plate 7 from that report (not presented herein) showed the locations of these wells, annotated with values for transmissivity (T) and hydraulic conductivity (or permeability, herein denoted by symbol P). That report noted that T and P varied considerably over quite short lateral distances within the alluvial aquifer, and suggested that this was because T and P values were calculated from water level drawdowns in the pumping wells rather than from aquifer test data from nearby observation wells. Use of water level drawdown data from pumping wells to calculate T values may provide results that are strongly influenced not only by the properties of the aquifer, but also by the condition of the well casing and gravel pack, particularly with older wells.

Since 1985, a number of new alluvial water wells have been constructed and tested, and generally more accurate T and P values are now available for some of these new wells. In the eastern part of the alluvium, the SCWC Lost Canyon 2A and Mitchell 5B wells were constructed and tested in 1990 and 2001, respectively; these wells had calculated T values ranging from approximately 270,000 to 500,000 gallons per day per foot of aquifer (gpd/ft). This is consistent with the earlier T value of approximately 350,000 gpd/ft calculated for the SCWC Sand Canyon well, (located near Lost Canyon 2A), but is considerably higher than the T values of 96,000 gpd/ft and 81,000 gpd/ft previously calculated for the nearby, older Mitchell 5A and Lost Canyon 2 wells, respectively. This suggests that the higher value (on the order of 350,000 gpd/ft) is more representative of the transmissivity of the alluvial aquifer system in this area.

In the central area of the alluvium, near the Newhall Ranch Road bridge over the Santa Clara River, the Slade 1986 Report indicated NLF Well S2 displayed a T value of 61,200 gpd/ft and a P value of only 380 gallons per day per square foot (gpd/ft^2). More recent testing of VWC Wells S6, S7 and S8, constructed in 1999-2000 in this same central area, revealed T values of between 400,000 and 500,000 gpd/ft and hydraulic conductivities of approximately 3000 gpd/ft^2. Again, these higher values are likely more representative of the alluvial aquifer system in this area.

Finally, two alluvial wells (VWC W-9 and W-10) were constructed in San Francisquito Canyon in 1991 and 1999. Testing revealed T values of 118,000 gpd/ft for W-10 and an extremely high value of 750,000 gpd/ft for W-9. Whereas the W-9 value may be anomalously high, even the lower T value for VWC W-10 is approximately twice the T values that were previously calculated from Edison efficiency test data for older wells in that area.

Geohydrology

General Statement

Within an aquifer, the amount of groundwater in storage is the total volume of water that exists in underground storage at a particular time, and that could become readily available for extraction by wells. Groundwater within the alluvial aquifer system in the study area occurs under unconfined (water table) conditions, and the amount of groundwater in storage in this aquifer depends on: a) the total volume of the alluvial sediments; b) the specific yield of those sediments, and; c) the proportion of those sediments that is saturated with groundwater.

Because the volume and specific yield of an aquifer do not generally change over time, the amount of groundwater in storage in the alluvial aquifer is directly related to the saturated thickness, which is in turn indicated by measured groundwater levels in water wells within the alluvial sediments. A rising water table increases the thickness of the saturated water-bearing section, and results in an increasing volume of groundwater in storage, whereas the reverse is true for a declining water table.

Because groundwater levels in the alluvial aquifer system are strongly influenced by local rainfall and recharge (a highly variable factor in southern California), the amount of groundwater in storage in the alluvium has varied considerably over the past 50 to 60 years as the local climate has experienced periods of both higher than average rainfall (wet years) and lower than average rainfall (dry years). For example, in November 1965, at the end of a severe 21-year long dry period (see Figure 2.1), groundwater levels in the alluvial aquifer system were at their lowest recorded levels and the amount of groundwater in storage in the alluvium was calculated at 107,000 AF (Slade 1986 Report). Conversely, in April 1945, at the end of a 10- to 11-year period of above average rainfall, groundwater elevations were at their highest recorded levels and the amount of groundwater in storage was calculated to be approximately 201,000 AF (Slade 1986 Report).

In order to update the Slade 1986 Report, we have re-calculated the amount of groundwater in storage within the alluvial aquifer system based on water level data for the spring of 2000, a recent period for which widespread water level data are available.

Groundwater Storage Capacity

The procedure for re-calculating the amount of groundwater in storage in the alluvial aquifer system is the same as was performed for the Slade 1986 Report, and is summarized as follows:

1. Subdivision of the alluvial aquifer into individual groundwater storage units.
2. Assessment of the total thickness of potentially saturated sediments in each storage unit.
3. Calculation of the thickness of saturated sediments in each storage unit, based on groundwater elevations for the period of interest in other nearby wells (Spring 2000, as seen on Plate 4.2).
4. Grouping of earth materials described on drillers' logs into categories based on grain size, and assignment of specific yield values to each category of earth materials.
5. Computation of groundwater in storage (GW_{st}) using the equation:

   $$GW_{St} = AmS_y$$

   Where A = the surface area of the storage unit, m = the saturated thickness of the aquifer, and S_y = the assigned specific yield.

Storage Units and Saturated Thicknesses

Because the alluvial sediments vary in character, thickness, and hydrogeologic properties, we have again subdivided the alluvium into the same smaller, more manageable groundwater storage units, as was done for the Slade 1986 Report. The boundaries of these units were again taken to coincide with surface or subsurface hydrogeologic boundaries, or topographic features such as canyon "narrows", obvious surface water divides, or similar features. Plate 4.5 – Map of Alluvial Groundwater Storage Units – illustrates the locations of the groundwater storage units and subunits for the alluvial aquifer system as used herein and as originally delineated in the Slade 1986 Report.

The storage units, and the methods used to determine their volume and saturated thickness are essentially unchanged from those presented in the Slade 1986 Report; a detailed description of these methods can be found in that report. However, the following are the salient points:

1. The water table surface was determined by contouring water level elevations for Spring 2000 and assigning an average water level elevation to each groundwater storage subunit within the alluvial aquifer area. The saturated thickness of each storage subunit was then defined as the distance between the average water table surface in that subunit and the bottom (base) of the alluvium in that subunit.
2. Within storage subunits where no water level elevation data were available for Spring 2000 (also see Plate 4.3), water level elevations for that subunit were estimated using 1985 water level elevations that were adjusted (generally downwards) to match Spring 2000 conditions.
3. The saturated volume of each subunit was calculated by multiplying the surface area of each subunit by the saturated thickness, and then reducing each volume by 25% to account for the fact that the sides and bottom of each alluvial subunit have the form of a generally U-shaped channel rather than a perfect rectangle.

The actual area and volume calculations for each storage subunit (see locations on Plate 4.5) were carried out using in-house GIS software.

<u>Specific Yield Values</u>

The specific yield of an aquifer is that percentage of the total volume of contained groundwater that will drain from the aquifer under the influence of gravity. The remaining portion of the groundwater within the aquifer materials is held in-place during gravity drainage by such actions as molecular forces and capillary attraction.

Specific yield values for the alluvial aquifer materials were determined previously through an assessment of sediment types recorded on approximately 300 drillers' logs for alluvial water wells located throughout the study area (Slade 1986 Report). These same specific yield values, which ranged from 9 to 16 percent, were also used for each of the storage subunits in the updated storage calculations presented in this report.

Estimated Quantity of Groundwater in Storage

The estimated quantity of groundwater in storage within the alluvial aquifer system in the spring of 2000 is calculated by GIS methods to be approximately 161,000 AF (see Table 4.4 – Alluvial Groundwater in Storage Calculations). Because this volume was calculated using a GIS system and digitized versions of the original mylar maps used for the Slade 1986 Report, we have also re-calculated the previous groundwater in storage volumes for 1945, 1965, and 1985 as presented in the Slade 1986 Report. This was done to assess the consistency of the new computer calculations, and to allow comparison between the original calculations of groundwater in storage and the current ones presented at this time. The assessment shows that the variation between the GIS and manual calculations of the original storage volumes (presented in the Slade 1986 Report) is less than 1% in each case. When referring to these historic groundwater in storage volumes, this update report uses the new GIS calculated numbers, which differ only slightly from those presented in the original Slade 1986 Report.

Over time, groundwater levels and associated groundwater in storage in the alluvial aquifer have fluctuated, typically in response to wet and dry conditions as they affect water levels and storage in the eastern portion of the alluvial aquifer. However, there has been no long-term, progressive decline in the amount of groundwater in storage in the alluvium that could be considered indicative of overdraft conditions.

Assessment of Operational Yield

The perennial yield of a groundwater basin was considered in the Slade 1986 Report to be the average annual amount of groundwater that may be extracted over the long-term from the basin by pumping without causing undesirable effects; in essence, it was considered to be a practical rate of annual groundwater withdrawal. The range of undesirable effects can include such things as ground subsidence, a decrease in water quality, or continuous and long-term water level declines in the aquifer. The primary undesirable effect in the alluvial aquifer in the Valley would be a continued and progressive decline in groundwater levels, leading to a permanent loss of groundwater in storage and to excessive pumping lifts. Were this situation to occur, the aquifer would be considered to be in overdraft.

The phrase "continued and progressive decline" is the key to understanding the concept of overdraft. Groundwater levels within the alluvial aquifer system experience temporary fluctuations in response to natural variations in recharge (such as from precipitation or upward flow of groundwater from the Saugus Formation aquifer system), and to changes in groundwater discharge such as pumping extractions. However, these temporary fluctuations in the storage of groundwater in the alluvial aquifer system are not continued or progressive; hence, they are not indicative of overdraft. Examples of this type of temporary fluctuation can be seen in the hydrographs for the SCWC Mitchell Well 5A on Figure 4.4 and SCWC North Oaks East Well on Plate 4.4. During periods of reduced rainfall, as in the periods 1969-1976 and 1983-1991, water levels in these wells declined by 75 ft or more, but these temporarily depressed water levels were clearly seen to recover quickly to their pre-drought levels once rainfall (and recharge) returned to more typical long-term average values. The recent decline in water levels in these wells is in response to the reduced rainfall conditions that began in 1999; the trends in rainfall over time are illustrated by the rainfall accumulated departure curve that is also provided with the hydrograph.

Background

The Slade 1986 Report calculated a "practical or perennial yield" for the alluvial aquifer in the range of 31,600 to 32,600 AF/yr. In deriving this perennial yield value, that study relied on the information available at that time, using the so-called Pumpage and Change-in-Storage method and a base period from 1958 to 1985. That method calculates the changes in storage within an aquifer over a period of time (the base period) that is sufficiently long enough to average out the influence of these temporary water level fluctuations. Groundwater extractions by pumping are then compared to the changes of groundwater in storage. The average annual level of pumping that would maintain the amount of groundwater in storage at a relatively constant figure on a long-term basis (i.e. no overdraft) is considered a reasonable estimate of the perennial yield.

Although that method is used because difficult-to-quantify terms such as recharge and subsurface outflow are not required, the method does have its drawbacks as described in a review of several perennial yield studies of the Yucaipa Valley of southern California (David

Keith Todd Consulting Engineers, 1987). Firstly, because the method works best in aquifers that are fully developed or possibly in overdraft, and where recharge does not play an important role in determining the amount of groundwater in storage, the method may be less reliable in aquifers where these assumptions are not met. As discussed previously, water level hydrographs of alluvial water wells illustrate clearly that: a) the alluvial aquifer is not in overdraft; and b) rainfall recharge will rapidly increase the amount of groundwater in storage, particularly in the alluvium east of the mouth of Bouquet Canyon.

Secondly, because the calculation method relies on average pumping rates and net changes in storage over time, it does not consider cumulative or progressive changes in the hydrology of a basin such as changing land use patterns, or an increase in imported water. The Slade 1986 Report (pg. 87) states specifically that "no recharge of imported water was assumed."

Current Conditions

Current hydrologic conditions in the Valley have in fact changed dramatically over the past twenty years, by such factors as the increased importation of water, the increase in the annual volumes of reclaimed water released to the alluvium, and the rapid conversion of agricultural and ranch lands to urban and suburban uses. In particular, the importation of SWP water has risen from approximately 1,100 AF/yr in 1980 to over 32,000 AF/yr in 2000. Much of this imported water is eventually discharged by the two local WRPs directly into the alluvium of the Santa Clara River. Combined discharges from these two WRPs totaled 19,000 AF in 2000, and this water is directly available for recharging the alluvial aquifer system along the Santa Clara River. Additional recharge comes from the proportion of deep percolation of SWP water that has been used for outdoor irrigation throughout the region.

The effects of this additional available recharge can be seen in the hydrograph for VWC Well Q2 (see Figure 4.3), located downstream of the discharge point for the Saugus WRP. From 1956 to 1970, a period during which groundwater production from the alluvial aquifer system averaged approximately 37,000 AF/yr, water levels in this well were typically at depths of 70 to 75 ft bgs. These water levels recovered rapidly to typical levels of approximately 25 to 30 ft bgs when alluvial groundwater production declined significantly in the early 1970s, eventually reaching an average of just 23,000 AF/yr between 1980 and 1990. However, when alluvial groundwater production again increased to approximately 35,000 AF/yr (between 1990 and 2000), water levels in Well Q2 (and other nearby wells) did not show a corresponding decline. In fact, water levels in Well Q2 are currently at or near their historic highs in spite of the higher alluvial annual groundwater extractions in the past 10 years.

Because of the progressive changes in the local hydrology over time, and the significance of imported SWP water in recharging the alluvial aquifer, simply re-calculating the perennial yield of the aquifer by updating the prior Pumping and Change-in-Storage calculations would not provide an accurate or useful value.

Operational Yield

One of the disadvantages of utilizing perennial yield as a basis for managing pumpage from an aquifer system is that it represents a long-term average value for annual yield. There is a potential for the perennial yield value to be interpreted as a not-to-exceed volume, with a related potential for pumpage above the perennial yield value in any given year to be interpreted as "overdraft". A recently advanced concept intended to deal with such misinterpretations is that of operational yield. Operational yield can be defined as a fluctuating value of pumpage that may be above or below the perennial yield in any given year, and that varies as a function of the availability of other water supplies. The basic intent of the operational yield value is that it should not exceed the perennial (or average) yield of the groundwater basin over multi-year wet and dry cycles.

The operational yield concept includes flexibility of groundwater use by allowing increased pumping during dry periods and increased recharge (direct or in-lieu) with supplemental water when it is available in wet/normal rainfall periods. The operational yield protects the aquifer by helping to assure that groundwater supplies are adequately replenished on a long-term basis from one wet/dry cycle to the next. In the Valley, historical groundwater data demonstrate that the alluvium has been, and continues to be developed within its long-term sustainability (i.e. no continuous lowering of water levels, no notable trend toward degradation of groundwater quality, etc.). Limited historical data for the Saugus Formation show no lowering of water levels or degradation of water quality where it has been developed at known well locations.

It is evident from observation of alluvial aquifer response to average pumping over the last several decades, and its response to pumping in individual years, that this aquifer system can be operated at a higher average pumping rate over a wide range of yearly pumping rates without inducing undesirable conditions that would be indicative of "overdraft," i.e., long-term continuous and progressive decline in water levels and in groundwater in storage. This observation is particularly evident since the initiation of supplemental SWP water deliveries in 1980. As a result, operational yield of the alluvial aquifer system or the yearly yield for operating purposes, could range from an individual annual pumping volume as low as about 20,000 AF, to an individual annual pumping volume as high as about 45,000 AF. The ultimate goals, of course, would be to avoid both short-term adverse impacts as a result of year-to-year fluctuations in pumping, and to avoid long-term adverse impacts such as continuously lowered water levels and storage in this aquifer system.

Recognition of historical alluvial aquifer response to the wide range of annual pumping and the higher average rate of pumping in recent years has led to the following two plans regarding operation of this aquifer system: 1) development of an UWMP that includes water supply from the alluvium within both the long-term yearly operational range and the recent (last ten years) average pumping capacity; and 2) commitment via an MOU process between the Santa Clarita Valley Water Purveyors and the downstream United Water Conservation District to develop a numerical groundwater flow model in order to analyze in greater detail how this aquifer system can be operated in the future to optimize its yield without adverse impact either to the aquifer (avoidance of depressed water levels and depleted storage) or to the environment associated with the aquifer (avoidance of decreased stream flows, avoidance of depleting riparian vegetation, etc.).

In summary, the combination of historical observations and current planning has led to the current conclusion that the alluvial aquifer system can be operated over a wide range of pumping volumes in any given year, on the order of 20,000 to 45,000 AF, and on a long-term average basis can be operated at an average pumping volume on the order of 10 percent higher than was reported as a "practical or perennial yield" in 1986. As summarized in the UWMP, the operation of the alluvium will typically be in the 30,000 to 40,000 AF per year range for most types of normal or wet years, with an expected reduction into the 30,000 to

35,000 AF per year in dry years.

Water Quality

Groundwater quality is affected by the relative concentrations of dissolved inorganic constituents, organic chemicals, and entrained organisms such as bacteria. This report discusses only the inorganic constituents and organic chemicals in the local groundwater.

The quality of surface water percolating into an aquifer is affected by such factors as the type of earth materials over which the surface water flowed, and the type and location of possible surface contaminants the water might encounter prior to infiltration. After percolation, the water quality is further influenced by such factors as: the lithology and age of the earth materials through which it flows; the rate of groundwater flow; the amounts, rates and locations of recharge; fluctuations in basin-wide water levels; potential contamination due to improperly constructed or destroyed wells; the location and quality of artificially recharged water; and the proximity of irrigated lands or industrial facilities from which degraded water might percolate into the aquifer system.

Groundwater Character

Groundwater character, as illustrated on a Stiff water quality pattern diagram, is defined by the relative proportions of the major dissolved anions and cations within a water sample. In most groundwater, these major ions include the cations calcium, magnesium and sodium, and the anions bicarbonate, sulfate and chloride. As illustrated on Plate 4.6 – Map of Alluvial Wells, *Stiff Pattern Diagrams – the groundwater within the alluvial aquifer system changes in* character as it moves from east to west across the valley floor. In the easternmost part of the Valley, near NCWD's Pinetree wells, the groundwater has a distinctive calcium bicarbonate (Ca-HCO_3) character, with only minor proportions of the other cations and anions. Moving westward down the Valley, the relative proportion of sulfate (SO_4) anions begins to increase such that groundwater in the area between the SCWC Honby and Stadium wells displays both a Ca-$HC0_3$ and a calcium sulfate (Ca-SO_4) character, depending on the particular well. Wells in the central part of the alluvium, between the mouth of Bouquet Canyon and I-5, show a mixed calcium-bicarbonate-sulfate (Ca-$HC0_3$-$S0_4$)

character. West of I-5, the groundwater within the alluvium has a $Ca\text{-}SO_4$ character (see Plate 4.6).

Within the tributary canyons for which requisite water quality data are available, alluvial groundwater within Bouquet Canyon displays a consistent $Ca\text{-}HC0_3$ character, whereas in San Francisquito Canyon a $Ca\text{-}SO_4$ water predominates. In Castaic Creek, groundwater appears to change from a $Ca\text{-}SO_4$ character in the upstream reaches near Castaic Dam, to a $Ca\text{-}HC0_3\text{-}S0_4$ character in the middle reaches near the I-5 bridge, and then back to $Ca\text{-}SO_4$ character in the lower reaches of the creek. This sulfate-rich groundwater within the alluvium of Castaic Creek may be one of the main sources for the higher sulfate groundwater conditions known within the alluvium west of I-5.

Inorganic Constituents

Two important inorganic components in groundwater from the alluvial aquifer system include nitrate (as NO_3), which has a State Primary Maximum Contaminant Level (MCL) of 45 milligrams per liter (mg/l) for domestic use, and the TDS concentration; the State Secondary MCL for TDS is expressed as a range with the lower level set at 500 mg/l and the upper level set at 1000 mg/l. No fixed consumer acceptance contaminant level has been established for TDS.

As with water character, the concentrations of nitrate and TDS within the alluvium show measurable changes as one moves from the eastern to the western sides of the Valley. In the eastern portion of the area (near the NCWD Pinetree wells), nitrate concentrations average approximately 14 mg/l, and TDS concentrations average approximately 550 mg/l.

In this easterly area near SCWC's North Oaks wells, average nitrate concentrations are approximately 27 mg/l and TDS is approximately 608 mg/l. Nitrate concentrations in this area are among the highest within any portion of the alluvial aquifer, although still well below the MCL for nitrate as NO_3 of 45 mg/l. Elevated nitrate concentrations in this area may originate from subsurface septic systems located in the unsewered tributary canyons north and south of the main Santa Clara River, or from the former Canyon Park Hog Ranch, located some distance south of the Santa Clara River; water samples from alluvial monitoring wells on the hog ranch property have reportedly recorded nitrate concentrations as high as 1816 mg/l (Mr. Steve Cole, SCWC, personal communication, 2001). This former hog ranch is reportedly being remediated under the direction of the Regional Water Quality Control Board – Los Angeles Region.

In the area between SCWC's Stadium and Honby wells, just upstream from the mouth of Bouquet Canyon, nitrate concentrations average 22 mg/l and TDS averages 664 mg/l. Just west of Bouquet Canyon, wells in VWC's Pardee wellfield have average nitrate concentrations of 27 mg/l and average TDS values of 706 mg/l. The relatively elevated nitrate concentrations in these wells (although still well below its MCL of 45 mg/l) may be influenced a number of possible factors, including former agricultural activities in this area that used nitrate-bearing fertilizers, or by the lack of deep cement sanitary seals in these former agricultural production wells.

Groundwater from five NLF agricultural-supply wells in the area west of I-5 has an average nitrate concentration of just 6.6 mg/l, despite the ongoing agricultural operations in this part of the Valley. These low nitrate values are likely due to dilution of the higher nitrate concentrations found in upstream groundwater by relatively low nitrate water from three possible sources. The first possible source is water from the Saugus and Valencia WRPs, where nitrate concentrations in the discharge water average approximately 5 and 23 mg/l, respectively. These two plants discharged a total of approximately 19,000 AF of water in 2000. The second possible source of low nitrate water is underflow of groundwater from Castaic Creek Canyon, where groundwater has average nitrate concentrations of approximately 6 mg/l. Finally, the third possible source of low nitrate water is the area west of I-5 where groundwater from the Saugus Formation is considered to be discharging into the alluvium. Saugus Formation groundwater has nitrate values that are typically lower than those in the alluvial groundwater.

TDS concentrations, on the other hand, are highest in the alluvial groundwater west of I-5, averaging approximately 1000 mg/l in the five NLF agricultural-supply wells mentioned above. The Slade 1986 Report discusses some possible sources of the high TDS values in this area, including irrigation return, WRP effluent, oilfield activities, and runoff from surface drainages where sedimentary rocks are cemented with gypsum or anhydrite ($CaSO_4$ minerals). Another possible cause of the high TDS values in this portion of the alluvium may be groundwater movement from the Saugus Formation into the alluvium.

Other Constituents

A search of the California Department of Health Services (DHS) water quality database reveals that between 1985 and 2000, no VOCs were detected in alluvial municipal-supply wells in the Valley at concentrations exceeding their respective MCLs. Some VOCs were detected in lower concentrations sufficient to require reporting to DHS, but many of these were disinfection byproducts such as chloroform, that result from chlorination of water at the wellhead for disinfection purposes prior to delivering the water into the distribution system.

Perchlorate (ClO_4), a component of rocket fuel, and related chemicals, have been detected in groundwater monitoring wells and in one now-abandoned industrial water well on the north side of a former industrial facility located in the hills southeast of Bouquet Junction. The current DHS advisory action level for perchlorate is 4 micrograms per liter (μg/l). No perchlorate has ever been detected in any of the municipal-supply water wells located in the alluvial aquifer system along the Santa Clara River in this region (see Plate 4.1 for locations of these alluvial-supply water wells).

SECTION 5

HYDROGEOLOGIC CONDITIONS IN THE SAUGUS FORMATION AQUIFER SYSTEM

Water Wells

According to available historic records, the first known water well specifically constructed to extract water from the Saugus Formation aquifer appears to have been NCWD Well No. 1, drilled in 1954 (Slade 1988 Report). At the time of that Slade 1988 Report, 22 Saugus Formation water wells were known to have been drilled in the region. As of 1988, 11 of the known Saugus Formation water wells were considered to be on active or inactive status, whereas the other 11 had been either abandoned or destroyed. NLF Well 155, which was listed as destroyed in the Slade 1988 Report, is now known to have only been abandoned (i.e., the pump has been removed from the well). The current condition of this well is not known. Plate 5.1 – Map of Saugus Formation Well Locations – illustrates the locations of known historically-drilled Saugus Formation wells in the Valley.

Between 1988 and 2001, eight additional Saugus Formation water wells were drilled and constructed in the Valley (refer to Plate 5.1). Of this group of 30 historically known water wells in the Saugus Formation, 17 either are in active operation, or are on some type of inactive or standby status. Table 5.1 – Construction Details for Existing Saugus Formation Wells – summarizes the relevant construction details for each of the existing wells, along with the operational status of each of those wells as of 2001. Also listed on Table 5.1 are the construction details for a groundwater monitoring well drilled in 1999 adjacent to new VWC 205; this groundwater monitoring well (205M) is used solely to monitor water levels and/or water quality in the Saugus Formation.

The remaining 13 wells of the 30 known historically-drilled wells in the Saugus Formation have been destroyed (data for the privately-owned Smiser well are unclear whether it is abandoned or destroyed at this time). Table 5.2 – Destroyed Saugus Formation Water Wells – summarizes the known construction details for those wells which have been reported to be destroyed as of 2001.

Note: NCWD - 9 to be destroyed in 2001

All but one of the existing Saugus Formation water wells are located in the southern structural block, that is, south of the Holser and San Gabriel faults (refer to Plates 3.1 and 5.1). Only the privately-owned Lombardi-Anden well is located within the central structural block (between the two faults), and there are no known existing Saugus Formation wells north of the San Gabriel fault. Historically, only one known attempt has been made to drill and construct a Saugus Formation water well in the area north of the San Gabriel fault where the lower and geologically older portion of the Saugus Formation (i.e., Sunshine Ranch member) is known to exist. That well (VWC 202) did not produce a sufficient quantity of groundwater of acceptable quality for municipal-supply purposes and was subsequently destroyed.

Maximum casing depths for existing Saugus Formation wells range from 675 ft for NCWD Well No. 9, to 2040 ft for the privately-owned Lombardi-Anden well. The depths to the top of the uppermost perforations in existing wells range between 200 and 950 ft bgs, whereas the depths to the base of the perforations range between 674 and 2000 ft bgs.

Pumping capacities in Saugus Formation wells for which data exist, have ranged from approximately 100 gallons per minute (gpm) in wells completed in the lowermost Sunshine Ranch Member near the outer margin of the formation, to rates in excess of 3000 gpm in wells located near the center of the Saugus Formation along the floor of the Valley.

New Wells

Between 1988 and May 2001, eight new Saugus Formation water wells were drilled and constructed in the Valley. The currently inactive SCWC Saugus No. 1 and No. 2 wells, and the currently active NCWD Well No. 13, were drilled and constructed along the South Fork of the Santa Clara River. New Saugus Formation wells along Valencia Blvd include the currently active VWC Well 201, and VWC Well 205. This latter water-supply well also has a 6-inch diameter monitoring well (VWC 205M) which is located approximately 30 ft from the main well, and which was completed with an almost identical perforated interval and casing depth. In the hills in the southwest part of the Saugus Formation outcrop area is the currently active, privately-owned Stevenson well (formerly known as the Poe well). The currently inactive Lennar-Anden well is located in Hasley Canyon. Finally VWC 202 was drilled and constructed in San Francisquito Canyon, but was subsequently destroyed for the reasons stated above; refer to Plate 5.1 for locations of these wells.

One additional attempt to drill and construct a new Saugus Formation water well in 1993 (VWC 203, located south of Magic Mountain Parkway) had to be terminated and the pilot borehole was destroyed after the contractor encountered technical problems during the drilling phase of the project. However, a detailed geologic log of the drill cuttings from the pilot hole and an electric log of the borehole were completed prior to permanent destruction of the borehole.

Destroyed Wells

As mentioned above, VWC Well No. 202, located in San Francisquito Canyon, was destroyed shortly after its construction in 1990.

In addition, recent discussions with the Ranch Manager at the Smiser Farm located near the I-5 Freeway and Lyons Avenue (personal communication, November 2000) suggest that the Saugus Formation water well on that property was abandoned and covered over sometime after 1988. RCS geologists were unable to locate this well during a brief visit to the property in the fall of 2000, and the date and method for destruction of this well are not known.

Finally, NCWD Well 8 is reported to have been destroyed in 1987, and NCWD Well 9 was reportedly slated for destruction in 2001.

Privately-Owned Domestic Wells

An unknown number of privately-owned, domestic-supply water wells within the Saugus Formation likely exist in some tributary canyons to the Santa Clara River (such as in the upper portion of Hasley Canyon). These wells are thought to provide water primarily for domestic-supply purposes to single-family dwellings and/or ranches that lie outside of the service areas of the local water purveyors. Because the Saugus Formation crops out at or very near ground surface in these areas, the wells are probably relatively shallow, on the order of 100 ft to perhaps 300 or 400 ft in total depth. Maximum pumping rates in such wells would typically be in the range of a few tens of gpm.

Groundwater Occurrence, Recharge and Discharge

Depending on location, groundwater within the Saugus Formation may exist under confined, semi-confined or even unconfined (water table) conditions. In the center of the Valley (refer to Plate 3.1 and to Plate 5.1), the sedimentary layering of the formation is nearly horizontal, and confining layers of low permeability (fine-grained silts and clays) limit groundwater movement in an upward or downward direction. As a result, groundwater in these areas occurs under pressure within the intervening sand and gravel units, and water levels in Saugus Formation water wells are above the top of the perforated casing intervals that intersect coarse-grained aquifer units, indicating confined or semi-confined conditions.

In contrast, near the lateral margins of the Saugus Formation, the sedimentary layering is tilted downward toward the center of the "bowl," and the permeable sand and gravel beds of the formation are either exposed directly at ground surface, or they are in direct contact with overlying, highly permeable alluvial sediments or terrace deposits. In these areas, the Saugus Formation aquifer may be under unconfined, water table conditions.

<u>Recharge</u>

Direct natural recharge to the Saugus Formation occurs via deep percolation of rainfall in the outer portions of the outcrop area where the permeable sand and gravel beds are either exposed at ground surface or lie directly beneath the relatively thin, permeable terrace deposits. Natural recharge to the Saugus Formation also takes place in the eastern end of the outcrop area due to leakage from overlying portions of the saturated alluvium, as originally discussed in the Slade 1988 Report and as corroborated by recent work by CH2M Hill (Newhall Ranch ASR Impact Evaluation, 2001).

Man-made sources of recharge to the Saugus Formation include deep percolation of agricultural and landscape irrigation water in areas where this formation is exposed at ground surface. Urban developments (residential, office, and recreational lands) occupy approximately 9600 acres (17%) of the Saugus Formation outcrop area, and are likely to provide significant amounts of irrigation recharge. On the other hand, direct recharge from infiltration of excess agricultural irrigation is likely to be a fairly minor source of recharge to the Saugus Formation because most agricultural land in the Valley is situated atop Quaternary alluvium.

To date, deliberate artificial recharge of the Saugus Formation via injection wells or highland spreading basins has never been undertaken in the region. Importantly, however, an injection and recovery study carried out in 2000 in the vicinity of VWC Well No. 205 has demonstrated the feasibility of operating at least a limited ASR program in the Saugus Formation within the Valley (Slade & Associates, LLC, February 2001; and Newhall Ranch ASR Impact Evaluation, 2001).

<u>Discharge</u>

Discharge from the Saugus Formation has historically occurred primarily via groundwater extractions for municipal- and agricultural-supply purposes, but also via natural discharge to the overlying Quaternary alluvium in the western portion of the Saugus Formation (CH2M Hill, 2001).

Depth to Base of Fresh Water

The maximum depth to which fresh groundwater occurs within the Saugus Formation (the base of fresh water) can be determined with some accuracy by examining oil well e-logs, and this has been done for approximately 250 e-logs of oil wells and water wells located throughout the Valley. On some e-logs, the vertical transition from the overlying fresh water to the underlying brackish or saline water is very abrupt and unambiguous. On other e-logs, the transition from fresh water to saline water is gradual and may occur over a vertical distance of hundreds of feet. In such cases, and to be conservative, the base of fresh water was selected, insofar as possible, at the top of the zone of transition from fresh water to saline water.

Plate 3.3 – Geologic Cross Section Z-Z' - provides our interpretation of subsurface conditions within the Saugus Formation in a west to east direction along the main reach of the Santa Clara River (see Section 3 of this report); the basis for the subsurface interpretations was the analysis and correlation of e-logs of wildcat oil wells and water wells. Plate 5.1 illustrates the surface location of this new geologic cross section, together with the lines of geologic

sections A-A' through F-F' that were originally prepared for the Slade 1988 Report (those cross sections are not reproduced herein).

The interpretation of the depth below ground surface to the base of fresh water (i.e. the thickness of fresh water-bearing deposits) within the Valley was originally published as Plate 5 in the Slade 1988 Report. The items of principal interest include:

1. Northeast of the San Gabriel fault, the maximum depth to the base of fresh water within the Saugus Formation is approximately 1500 ft. By comparison, the maximum total thickness of the Saugus Formation, based on e-logs, is on the order of 2000 ft in this area.
2. In the wedge-shaped central fault block between the San Gabriel fault and the Holser fault, the maximum depth to the base of fresh water within the Saugus Formation is approximately 5500 ft. In this area, the maximum total thickness of the Saugus Formation is approximately 8500 ft.
3. Southwest of the Holser fault, the maximum depth to the base of fresh water within the Saugus Formation is approximately 5000 ft. The Saugus Formation obtains a maximum total thickness on the order of 7500 ft in this area.

Groundwater Extractions

Groundwater production from the Saugus Formation has been primarily for municipal-supply purposes, particularly in recent years. Only NLF Well No. 156, the Lennar-Poe well, and possibly the Smiser well are currently or were recently used for agricultural and/or industrial purposes.

Figure 5.1 - Historic Saugus Formation Groundwater Production – illustrates, as a bar chart, the historic trends in Saugus Formation groundwater production since the mid-1950s, the earliest date for which production records are available (see also Table 5.3 – Saugus Formation Groundwater Production 1986-2000). Historically, total Saugus Formation groundwater production has ranged from a low of approximately 550 AF/yr in 1954, to a high of approximately 15,000 AF/yr in 1991. For the ten-year period from 1991 to 2000, the average annual Saugus Formation groundwater production was approximately 8600 AF/yr (see Table 5.1). The total combined groundwater production from the Saugus Formation from 1954 through 2000 has been approximately 268,000 AF. These figures do not include annual pumpage by the smaller domestic-supply water wells known to exist at the single-

VWC 205 became active in 2001
VWC 159 used for irrigation only

family homes and ranches in certain tributary canyons in the Valley that lie outside the service areas of the major water purveyors. Total annual production from all of these privately-owned, domestic-supply wells in the Saugus Formation may be on the order of 100 AF.

Groundwater production from the Saugus Formation is concentrated in the central and southern portions of the Valley where the majority of the currently producing Saugus Formation municipal-supply water wells are concentrated. These existing wells are located within the southern structural block, south of both the Holser and San Gabriel fault zones. The majority of the Saugus Formation groundwater production in 2000 was from two wells, namely, NCWD 12 (1767 AF) and VWC 160 (1332 AF); see Table 5.3 and Figure 5.1.

Between 1986 and 2000, NCWD accounted for between 33% to 82% of the total annual Saugus Formation municipal-supply groundwater production; in this same period, VWC production represented between 10% and 46% of the total annual production; SCWC production has been 0% to 32% of the total annual production in that time period; and NLF accounted for between 0% and 15% of the annual production from the formation. Annual production from such privately-owned, domestic-supply Saugus Formation wells is not known, but is unlikely to have exceeded a total of perhaps 100 AF/yr for all privately-owned wells in the region. This unmetered, privately-owned, domestic-type production represents roughly 1% of the average annual groundwater production from the Saugus Formation since 1986.

Plate 5.2 – Map of Saugus Formation Groundwater Extractions for 2000 – has been prepared to illustrate the spatial variability in recent groundwater extractions from the Saugus Formation. Data for Plate 5.2 were derived from information tabulated on Table 5.3 for the year 2000 for each active well. Annual groundwater extractions for each of the five active Saugus Formation water wells in 2000 are illustrated on Plate 5.2 via a circle centered on the respective well. The larger the diameter of the circle, the greater is the extraction for the particular well in 2000. The map scale used to illustrate the annual production for each well is: 1 inch equals approximately 667 AF or, ¾" = 500 AF. It must be noted that the circles (specifically, the diameter of the circles) graphed on Plate 5.2 are drawn to solely represent

the relative annual production volume (in AF) for each respective well. The diameter of the circle surrounding each well does not represent and should not be construed or interpreted to signify the area of pumping influence (the extent of the drawdown cone) of the particular well.

As seen on Plate 5.2, the greatest producer from the Saugus Formation in 2000 was NCWD-12, located in the South Fork area. The second highest production was from VWC-160 located along the main reach of the Santa Clara River. Privately-owned NLF-156, located near Castaic Junction, produced 374 AF of groundwater in 2000 for irrigation-supply purposes only.

Current Groundwater Levels and Flow Directions

In order to assess groundwater levels and flow directions in the Saugus Formation, we have compiled a database of over 2500 historic and recent Saugus Formation water level measurements from purveyor records, Edison Company well efficiency tests, and RCS data files. In addition, a number of field visits were made in the fall of 2000 to measure water levels in as many Saugus Formation wells as possible (including a few privately-owned wells) within a relatively short time frame. After correcting these fall 2000 water level measurements to mean sea level for each well, maps depicting contours of equal groundwater elevation for these Saugus Formation water wells were prepared. Because the Saugus Formation in those areas where Saugus Formation wells exist is largely confined or semi-confined, these water level elevations are considered to represent the elevation of the piezometric (pressure) surface within the Saugus Formation for that time period.

Plate 5.3 – Map of Saugus Formation Groundwater Elevation Contours, Fall 2000 – illustrates the interpreted groundwater elevation contours for the Saugus Formation for the fall of 2000, a recent period for which requisite data are available. This plate also shows the locations of the Saugus Formation water wells for which water level elevation data were available, and these wells are annotated with the respective well ownership, well number and water level elevation for fall 2000.

Key points from Plate 5.2 include:

1. Data points (i.e. Saugus Formation water wells) are not evenly or broadly distributed throughout the outcrop area of the Saugus Formation. Wells are generally concentrated along the South Fork of the Santa Clara River and in the community of Valencia, with only a few outlying agricultural or privately-owned wells in other areas. All but one of the known, existing Saugus Formation wells is situated within the southern structural block of the Saugus Formation, south of the Holser fault. No data are available for the region north of the San Gabriel fault because only one Saugus Formation well (now destroyed) has ever been drilled there. As such, the preparation of the Fall 2000 water level elevation contours has been restricted to areas near wells for which current data exist.
2. South of the Holser fault (*i.e.*, the Southern structural block), groundwater elevations range between approximately 1300 ft in NCWD Well No. 9, to approximately 976 ft in NLF Well No. 156. Groundwater in this southern structural block likely flows from the topographic highlands along the edge of the Saugus Formation northward towards the center of the Valley. Upon reaching the center of the Valley, which is delineated by the channel of the Santa Clara River, groundwater generally flows westward and then southwestward before discharging from the Saugus Formation into the alluvium in the area roughly between the I-5 Freeway and the western edge of the formation.
3. In the central structural block (between the Holser and San Gabriel faults), groundwater appears to also flow from the topographic highlands near the edge of the formation towards the Valley floor. In this central structural block, this regional flow appears to be towards the southeast. A confluence between the northerly and westerly flowing groundwater in the southern structural block, and the southeasterly flowing groundwater in the central structural block seems to occur in the vicinity of NLF Well No. 156.
4. Groundwater gradients within the Saugus Formation generally mimic topographic land surface gradients, in that they tend to be steeper in areas of steep topographic relief such as in the highlands south of the Valley, and considerably more gentle (flatter) along the Valley floor. Gradients range from roughly 150 ft/mile (0.028 ft/ft) between NCWD Well Nos. 9 and 7 near the edge of the Saugus Formation, to approximately 25 ft/mile (0.0047 ft/ft) between VWC Well No. 157 and NLF Well No. 156 along the Valley floor.

Hydrographs

Figure 5.2A through 5.2F – Representative Saugus Formation Hydrographs – provides graphs of the available static (non-pumping) water level records versus time for six Saugus Formation wells. Plate 5.4 – Map of Saugus Formation Hydrographs – shows several of these hydrographs on a map of the Saugus Formation. These wells (VWC No. 157 and 160

and NCWD Nos. 9, 10, 11 and 12) have been selected for evaluation because of their long, relatively continuous water level monitoring records. Examination of hydrographs for other Saugus Formation wells with shorter water level records (not presented herein) reveals similar patterns of water level fluctuation to those presented herein.

As illustrated on Figures 5.2A through 5.2F and Plate 5.4, historic static water levels (technically, the piezometric surfaces) in these active Saugus Formation water wells have typically fluctuated over time: the magnitude of these historic fluctuations varies with each well, but has generally ranged from a minimum of 50 ft to a maximum of 175 ft of water level change; these water level conditions are for wells that typically range in total casing depth between 750 to 2000 ft. Importantly, it is clearly evident from the hydrographs, that no long-term or continuous decline in water levels has occurred over time in any Saugus Formation water well. For comparison purposes, the depths to the upper limit and lower limit of perforated casing in each well are also shown on the six hydrographs on Plate 5.4.

Also shown on Figures 5.2A through 5.2F and Plate 5.4 are graphs of the cumulative departure from average annual precipitation for the period of 1950 to 2000; the trend of total Saugus Formation groundwater extractions over time are shown for comparative purposes on the figures also. The cumulative departure curve for rainfall illustrates trends in the amount of rainfall over time, such that when the curve is descending towards the right (such as from 1983 to 1991), an extended period of generally deficient precipitation (drought) is considered to have been occurring. In contrast, whenever the curve ascends to the right (such as from 1976 to 1983), an extended period of generally excess or increasing precipitation (wet period) has been occurring.

Water levels in Saugus Formation wells appear to fluctuate in response to patterns of increasing or decreasing rainfall, and to some extent to patterns of increasing or decreasing groundwater extraction from the Saugus Formation. It is somewhat difficult to differentiate the effects of rainfall vs. pumping on historic water levels because total Saugus Formation pumping has historically increased during dry periods, and decreased during wet periods.

Aquifer Parameters

The hydraulic properties (aquifer parameters) of Saugus Formation aquifers are used to help assess well yields, potential water level drawdown interference between pumping wells, and well spacing criteria, but are also useful for developing and calibrating numerical groundwater models. These key aquifer parameters (transmissivity and storativity) and the specific capacities of wells are typically calculated from water level drawdown and recovery data monitored during aquifer (pumping) tests. During the preparation of the original Slade 1988 Report, aquifer tests were performed in 1987 on five selected Saugus Formation water wells in order to provide data for the calculation of the aquifer parameters. Over time, additional aquifer tests have been conducted as part of the construction of each new Saugus Formation well and as part of the Saugus Formation ASR study carried out in 2000. Table 5.4 – Selected Saugus Formation Aquifer Parameters - presents the aquifer parameters calculated from the results of the original 1987 aquifer tests, as well those derived from the more recent tests. Locations of these Saugus Formation wells are shown on Plate 5.1.

Transmissivity and Storativity

Transmissivity, an important aquifer parameter, is a measure of the ability of an aquifer to transmit water to a pumping well, or to accept water from an injection well; it is expressed in units of gallons per day per foot of aquifer width (gpd/ft). Storativity, another important aquifer parameter, is a measure of the volume of water released to a pumping well, or accepted by an injection well, from a given volume of aquifer materials. Storativity is a dimensionless parameter and, thus, has no units. Both transmissivity and storativity values are calculated from water level drawdown and water level recovery data measured in non-pumping wells during an aquifer test.

Transmissivity values presented in the Slade 1988 Report ranged from lows of 3000 to 4000 gpd/ft in NCWD Well No. 9, to highs of 157,000 to 182,000 gpd/ft in VWC Well No. 160. A review of the spatial variability in transmissivity values for wells with such data indicates a general trend from lower transmissivity values near the southeastern edge of the Saugus Formation outcrop area near NCWD 9, to higher transmissivity values near the center of the Valley near VWC 160.

Storativity values from the 1987 aquifer tests were calculated from water level drawdown and recovery data measured in NCWD 12 during pumping of nearby NCWD 10. These storativity values were on the order of 10^{-4} (0.0001), with such values being considered typical of confined to semi-confined aquifer conditions.

Additional transmissivity values were derived from more recent aquifer test data obtained during construction and testing of SCWC Saugus Wells 1 and 2 (Slade, 1989 and 1990) and VWC 201 (Slade, 1990). Transmissivity values ranged from 60,200 to 70,300 gpd/ft for the two SCWC Saugus wells, respectively, and from 99,000 to 150,000 gpd/ft for VWC 201. These values are within, and toward the upper end of the previously calculated transmissivity values for the Saugus Formation. Storativity values calculated from these test results were 0.0001 (10^{-4}) for the SCWC Saugus wells, and 0.001 (10^{-3}) for VWC 201.

Transmissivity values were also calculated from the data derived from aquifer tests carried out as part of the 2000 ASR study. Calculated transmissivity data ranged from 66,000 to 76,000 gpd/ft for the pumping test of VWC 205, and from 44,000 to 65,000 gpd/ft for the pumping test of VWC 201 (see well locations on Plate 5.1). These values are in good general agreement with data from prior testing of Saugus Formation water wells (see Table 5.4). Storativity values calculated from these aquifer test data ranged from 10^{-3} to 10^{-4}, which is also in general agreement with previous data.

For the data generated from the ASR study, transmissivity and storativity calculations were carried out using the software program AQTESOLV, using the automatic curve fitting procedure. This permitted the rapid evaluation of several possible numerical solutions for each set of water level drawdown and recovery data. Using this software, it was found that the Hantush-Jacob solution for a leaky confined aquifer provided a good fit for the monitored water level data from VWC 205. This indicates that the individual aquifers within the Saugus Formation at this well site may exhibit some degree of vertical hydraulic connection.

Noteworthy during the pumping tests of the new Saugus Formation wells drilled since 1988 are the pumping rates utilized during the individual step drawdown tests. Step drawdown tests are the initial pumping tests conducted in a new well after its construction and are performed by pumping the well at 3 or 4 increasingly higher pumping rates (or steps), with each rate (step) lasting approximately three to four hours. After the step drawdown test is performed, a final constant rate discharge test (i.e., the aquifer test) is then conducted in each new well.

The ranges of pumping rates used during the step drawdown tests in each new municipal-supply Saugus Formation water well were as follows:

- NCWD-13 - 1100 gpm to 3350 gpm
- SCWC Saugus -1 - 2014 gpm to 3731 gpm
- SCWC Saugus 2 - 1721 gpm to 3740 gpm
- VWC-201 - 1767 gpm to 3788 gpm
- VWC-205 - 2440 gpm to 4000 gpm
- VWC-202 (now destroyed) - 115 gpm (constant rate only)

These data clearly reveal the relatively high pumping rates that have been achieved during the step drawdown testing of these Saugus Formation water wells. Each subsequent constant rate discharge test in these wells was conducted at rates in the range of 2500 to 3400 gpm, except for that in VWC-202. As noted previously, VWC-202 was destroyed shortly after its construction in 1991 due to its very limited pumping capacity and very low specific capacity; this well was constructed in San Francisquito Canyon within sediments of the Sunshine Ranch Member of the Saugus Formation, north of the San Gabriel fault.

Specific Capacity

Although technically not an aquifer parameter, the specific capacity of a well is commonly used as a measure of the yield of a well. It is calculated by dividing the discharge rate of a well (in gpm) by the total water level drawdown created in that well while pumping at that rate; it is expressed as gallons per minute per foot of water level drawdown (gpm/ft ddn). Specific capacity is not strictly an aquifer property, because it is affected not only by aquifer characteristics but also by the design, construction and condition of the well.

As illustrated in Table 5.4, historically known specific capacity values for Saugus Formation wells are typically on the order of 10 to 70 gpm/ft ddn. Values calculated from the results of pumping tests during the 2000 ASR study for both VWC 205 (20.4 gpm/ft ddn) and VWC 201 (29.9 gpm/ft ddn) are toward the lower end of the range for Saugus Formation wells in the region.

As a particular well ages, groundwater quality can also impact specific capacity because the casing perforations and the surrounding gravel pack may become clogged with mineral precipitates and/or bacterial growths, leading to an increase in head loss (increase in water level drawdown) for groundwater trying to enter the perforations. This, in turn, leads to a reduction in specific capacity over time and the eventual need for rehabilitation of the well.

Geohydrology

General Statement

The amount of useable groundwater in storage in the Saugus Formation was calculated in the Slade 1988 Report to be approximately 1.41 million AF. In that report, useable groundwater was defined as the groundwater contained only within potential sand and gravel aquifer beds and only between the depths of 500 ft below ground surface (bgs) and the shallower of either: a) a depth of 2500 ft bgs; or b) the base of fresh water within the Saugus Formation; or c) the base of the Saugus Formation. At that time, an upper limit of approximately 500 ft bgs was utilized as the shallowest that a Saugus Formation water well might be perforated while still minimizing potential water level drawdown interference with nearby alluvial water wells. More recent information on the thickness of the alluvium, and the degree of potential drawdown interference between adjacent Saugus Formation and alluvial water wells (based on testing conducted during the ASR project of 2000), has led us to adjust this upper limit from 500 ft bgs to 300 ft bgs for use in the revised calculations of groundwater in storage for this update report.

In order to update the 1988 calculations of groundwater in storage within the Saugus Formation, it was necessary to do the following: identify potential sand and gravel aquifer units from e-logs for a large number of widely distributed oil wells and water wells; calculate the total thickness of these potential aquifer units at each well location; determine the volume of these potential aquifer units both laterally and vertically; and then assign a specific yield factor to the various areas of the Saugus Formation. The details of these steps are provided below.

Potential Saugus Formation Aquifers

The Saugus Formation is not a single homogeneous aquifer, but rather it consists of numerous potentially water-bearing sand and gravel beds (aquifer units) of varying thickness that are interlayered with finer-grained silt and clay beds. These potential aquifer units were identified by their distinctive signatures on approximately 150 e-logs from oil wells and water wells distributed throughout the Valley. A practical approach to evaluate the feasibility of using a potential aquifer unit to calculate the total potential aquifer unit thickness for any given e-log was utilized in the original Slade 1988 Report. The basic criterion used in that evaluation was whether or not perforated casing would be placed adjacent to a particular sand or gravel unit in a hypothetical water well constructed at that location. Using this criterion, thin sand and gravel units bounded above and below by relatively thick, impermeable silt or clay beds were considered hydrogeologically isolated units and, thus, were not included in the total thickness calculations. To be consistent with that 1988 methodology, this updated report utilizes that same practical approach.

For the Slade 1988 Report, it was assumed that the deeper potential aquifer units at a particular location would actually contribute groundwater to a well constructed at that location. Until recently, there were no data to verify that original assumption. However, two downhole flow meter (spinner) surveys have been conducted in VWC 205, one under pumping conditions and one under non-pumping conditions (see well location on Plate 5.1). These tests revealed that groundwater is produced by this well throughout its entire perforated length (*i.e.*, from 820 to 1930 ft bgs). Specifically, the 1999 spinner survey (performed at a pumping rate of approximately 3400 gpm at the time the well was initially constructed) showed that 2223 gpm, or 65% of the total flow, was from the perforated zone of 820 to 1045 ft bgs. Flow from the remaining perforated zones ranged from: 190 gpm (6% of the total flow) at 1045 to 1270 ft bgs; 401 gpm (12% of the total flow) at 1270 to 1495 ft bgs; 368 gpm (11% of the total flow) at 1495 to 1720 ft bgs; and 218 gpm (6% of the total flow) at 1720 to 1930 ft bgs.

A more recent spinner survey of VWC-205 was conducted for the 2000 ASR project and its results corroborated the initial 1999 testing. The greatest production in VWC 205 was derived from two specific zones: the first zone between 820 to 960 ft brp (34.3% of the total pumping test rate of 2253 gpm), and the second zone between 1570 to 1700 ft brp (22.6% of total flow). The remainder of the groundwater production was distributed fairly evenly over the rest of the perforated intervals in this well. Both of these spinner surveys demonstrate that the aquifer units within the entire perforated thickness of the Saugus Formation at this well (to a depth of at least 1930 ft) are capable of providing groundwater to wells.

In February 2002, NCWD conducted a spinner survey under non-pumping conditions in NCWD No. 10 which is located in the South Fork area (see Plate 5.1). Preliminary results of this spinner survey under non-pumping conditions revealed that groundwater from the deeper perforated sections of the casing was moving upward in the well and outward through the shallower sections of the perforated casing (from Table 5.1, casing perforations are from 780 ft to 1544 ft bgs in NCWD No. 10).

<u>Total Thickness of Potential Aquifers</u>

Plate 3.2 in Section 3 presents a map of contours of equal thickness of potential sand and gravel aquifer units within the Saugus Formation, along with the individual data points (wells) used to create those contours. Potential aquifer units for this update report are now considered to be between the depths of 300 ft bgs and the shallower of either: a) depth of 2500 ft bgs; or b) the base of fresh water within the Saugus Formation; or c) the base of the Saugus Formation.

Key observations from this plate include:

1. The greatest thickness of potential aquifer units within the Saugus Formation occurs within the central structural block, adjacent to the Holser fault zone in the area where the fault alignment crosses the I-5 Freeway. In this area, the total thickness of potential aquifers is in excess of 1500 ft.
2. In the southern structural block, the area of greatest aquifer unit thickness (in excess of 1100 ft) occurs in part beneath the South Fork of the Santa Clara River. This suggests that historical drainage patterns during the original deposition of the Saugus Formation were, in part, similar to those of the present day.

3. North of the San Gabriel fault, the total thickness of potential aquifer units reaches a maximum interpreted thickness of between 500 and 600 ft. A large area north of the San Gabriel fault near the margin of the Saugus Formation outcrop area is interpreted as having no potential aquifer units at all due to the presence of the Sunshine Ranch Member of the formation; this member lies near the base of the formation and is comprised principally by fine-grained strata of relatively low permeability.

Storage Units and Thickness Zones

Because the storage calculations for the Slade 1988 Report relied on hand-drafted maps, the outcrop area of the formation originally had to be divided into smaller, more manageable storage units, before calculating the individual areas using a planimeter. The GIS database and software used in this current report simplified this process, and allowed a slightly different approach to be used.

On the contoured map of potential sand and gravel aquifer units (Plate 3.2), the regions between successive contours were assigned a thickness intermediate between the lower and upper contour values. For example, the region bounded by the 800 ft and 1000 ft contour lines was assigned a thickness of 900 ft. For regions bounded by only a single contour on one side and by one of the fault zones on the other side, a value 100 ft greater than the lower bounding contour was assigned; for example, a region bounded by the 1500 ft contour on one side and the Holser fault on the other would be assigned a thickness value of 1600 ft. The planar surface area, and the total volume of the potential aquifer units for each contour-bounded region, were then calculated using the GIS software.

Specific Yield Values

Specific yield is the volume of water that may drain by gravity from a given volume of aquifer materials, relative to the total volume of aquifer materials; it is typically expressed as a percentage. Specific yield is dependent primarily on the permeability and grain size distribution of the aquifer materials. Because the Saugus Formation aquifer units vary horizontally and vertically in both grain size characteristics and permeability, it was necessary to assign different specific yield factors to different areas of the formation.

The original Slade 1988 Report assigned conservative specific yield values that ranged only between 5 and 8 percent to the Saugus Formation in calculating the approximate volume of groundwater in storage. Because there is no available evidence to suggest that these values should be adjusted, we have retained the conservative 1988 values for specific yield for the updated calculations presented below.

Estimated Quantity of Groundwater in Storage

The estimated volume of groundwater in storage in the Saugus Formation is calculated by multiplying the total volume of potential aquifer units in each contour-bounded region by their assigned specific yield factors, and then summing the results for each region. This is rapidly accomplished using the GIS database.

Table 5.5 - Summary of Groundwater in Storage in the Saugus Formation – summarizes the results of these calculations. As shown, the updated estimate of groundwater in storage is approximately 1.65 million AF, an increase of roughly 18% over the 1.41 million AF calculated in the original Slade 1988 Report. This increase is due almost entirely to raising the upper limit of our depth zone of interest from 500 ft to 300 ft bgs as discussed previously.

The calculated volume of 1.65 million AF is still far less than the approximately 6 million AF estimated by Robson (1972) for the USGS. The difference between the two calculated volumes appears to be due to three main differences in the methods used. The first is that our calculations extend only to a maximum depth of 2500 ft bgs or to the base of fresh water, or to the base of the Saugus Formation (whichever is shallower), whereas Robson's calculations extended to depths as great as 3500 ft bgs. Second, Robson (his Plate 2, 1972) shows considerably thicker aquifer units (up to 2000 ft thick) compared to those determined for this present study, which measured a maximum total aquifer thickness of approximately 1600 ft. Third, the single specific yield value used by Robson (10%) for the entire Saugus Formation is considerably greater than those used in our calculations (5 to 8%).

Operational Yield

As discussed in the preceding Section 4 regarding the alluvial aquifer system, one of the disadvantages of utilizing perennial yield as a basis for managing the pumpage from an

aquifer system is that it represents a long-term average value for yield. There is a potential for the perennial yield value to be interpreted as a not-to-exceed volume, with a related potential for pumpage above the perennial yield value in any given year to be interpreted as "overdraft". A recently advanced concept intended to deal with such potential misinterpretations is that of operational yield. This is defined as a fluctuating value of pumpage that may be above or below the perennial (average) yield in any given year and that varies as a function of the availability of other water supplies. The basic intent of the operational yield value is that it should not exceed the perennial (or average) yield of the groundwater basin over multi-year wet and dry cycles.

The operational yield concept includes flexibility of groundwater use by allowing increased pumping during dry periods and increased recharge (direct or in-lieu) with supplemental water when it is available in wet/normal rainfall periods. The operational yield protects the aquifer by helping to assure that groundwater supplies are adequately replenished on a long-term basis from one wet/dry cycle to the next. In the Valley, historical groundwater data demonstrate that the alluvium has been, and continues to be developed within its long-term sustainability (i.e. no continuous lowering of water levels, no notable trend toward degradation of groundwater quality, etc.). Limited historical data for the Saugus Formation show no lowering of water levels or degradation of water quality where it has been developed at known well locations.

It is evident from observation of the response of water levels in the Saugus Formation to historical pumping that this aquifer system can be operated (pumped) over a range of capacities to at least 15,000 AF/yr per year without causing undesirable conditions that would be indicative of "overdraft," i.e. long-term continuous and progressive decline in water levels and in groundwater in storage. As a result, the operational yield of the Saugus Formation, or its yearly yield for operating purposes, could range up to an individual annual pumping volume on the order of 15,000 AF based on historical pumpage values available at this time. The ultimate goals, of course, would be to avoid both short-term adverse impacts as a result of year-to-year fluctuations in pumping, and to avoid longer-term adverse impacts such as continuously lowered water levels and storage in this aquifer system.

It is also evident from the analysis of aquifer extent, both spatial and vertical, and from the analysis of groundwater in storage, that historical Saugus Formation pumpage has been very small in comparison to aquifer thickness, groundwater in storage, and potential recharge (the latter as reported in the Slade 1988 Report). Recognition of the lack of any adverse impacts associated with historical Saugus Formation pumpage, and the latter observations of aquifer extent, groundwater in storage, and potential recharge has led to the following two plans regarding operation of the Saugus Formation aquifer system: 1) development of an UWMP that includes water supply from the Saugus Formation within the long-term yearly operational range on average (average/normal rainfall years), with short-term increases in single to multiple dry years into the range of 15,000 to 35,000 AF/yr; and 2) commitment via an MOU process between the Santa Clarita Valley Water Purveyors and the downstream United Water Conservation District to develop a numerical groundwater flow model in order to analyze in greater detail how the Saugus Formation aquifer system can be operated in the future to optimize its yield without adverse impact either to the Saugus Formation (avoidance of depressed water levels and depleted storage) or to the overlying alluvial aquifer system (avoidance of decreased flow into the alluvium) and associated environment effects.

In summary, the combination of historical observations and current planning has led to the current conclusion that the Saugus Formation can be operated at this time on a long-term average basis in the range of 7,500 to 15,000 AF/yr. Infrequently, during dry periods of one to three years, pumping operations can be ramped up from 15,000 to 25,000 AF/yr, and ultimately to 35,000 AF/yr if dry conditions continue. These latter increases would be temporary and would then return to or below the historical range of 7,500 to 15,000 AF/yr once rainfall patterns return to normal. As summarized in the UWMP, the operation of the Saugus Formation aquifer system will typically be in the 7,500 to 15,000 AF/yr range for most types of rainfall years, with possible short-term ramped increases in dry periods into the 15,000 to 35,000 AF/yr range. Such temporary and short-term increases above historic pumping volumes are unlikely to have an adverse impact on the Saugus Formation, and in particular, are unlikely to induce a permanent loss of groundwater in storage and/or a permanent decline in water levels. Any short-term water level decline or groundwater storage decline is expected to be restored upon return to the historical operating range on an average basis.

Water Quality

Groundwater Character

As illustrated on Plate 5.5 – Map of Saugus Formation Wells, Stiff Pattern Diagrams - groundwater in the Saugus Formation varies in character from: calcium-bicarbonate (Ca-HCO_3) in NCWD Well Nos. 7, 8, 10, and 12; to calcium-sulfate (Ca-SO_4) in NLF Well No. 156 and VWC Well Nos. 158 and 160; to sodium-bicarbonate (Na-HCO_3) in the privately-owned Lombardi/Anden well located further west within the central fault block.

Groundwater of Ca-HCO_3 character is generally considered to be representative of oxidizing conditions, indicative of meteoric (rain) water that has percolated and circulated in the aquifer system. The Ca-SO_4 character of groundwater obtained from wells in the central part of the Valley likely reflects a longer residence time of water in the aquifer system allowing the soluble, sulfate-bearing gypsum and/or anhydrite minerals within the Saugus Formation sediments to dissolve into the groundwater. The cause of the Na-HCO_3 character in the Lombardi-Anden well is unclear, but in any case is represented by the results of laboratory testing of only a single sample from this one well.

Aquifer Zone Isolation Testing

Aquifer zone isolation testing (zone testing) has been performed in at least three of the Saugus Formation municipal-supply water wells at the time of their construction. Zone testing is performed in the open borehole (pilot hole) for a new well, after the geologic log and the e-log have been completed, but prior to reaming the borehole and setting the well casing. The basic purpose of the zone testing is to obtain a groundwater sample for subsequent water quality laboratory analysis from the potential aquifer zone being tested.

Specifically, the procedure involves: selecting a potential aquifer zone to test using the geologic log and the e-log; setting an approximately 15- to 30-foot long perforated sampling tool to the desired depth beginning at the deepest aquifer zone to be tested (the tool is lowered into the open borehole at the bottom end of the drill string); placing a bentonite seal and a gravel pack above and below the perforated tool, and a gravel pack around the tool itself, in order to help isolate the perforated tool in the potential aquifer zone to be sampled; and lowering an air line inside the drill string and using an air compressor to inject high capacity/high pressure air into the air line. This injected air then essentially lifts the fluids from the isolated aquifer zone up within the drill string and to the ground surface. Airlifting continues until the fluids observed at ground surface are relatively clear, and then a water sample is collected for laboratory testing.

Zone tests were performed in SCWC-Saugus 1 at depths of 1510 to 1530 ft bgs and at 490 to 510 ft bgs. The analytical laboratory test results indicated the groundwater was Ca-Na-HCO_3 and Ca-SO_4-HCO_3 in character, with TDS concentrations of 410 mg/l and 530 mg/l, respectively.

Zone testing of VWC-202 (located along San Francisquito Canyon, north of the San Gabriel fault zone) was performed in four separate, 20-foot long zones between the depths of 280 ft and 810 ft bgs. Water quality in these zones ranged from Na-SO_4-HCO_3 to sodium chloride (Na-Cl). Both TDS and TH were relatively low, but iron, manganese and fluoride concentrations were relatively high.

Zone testing was also performed in NCWD-13, located in the South Fork area (see Plate 5.1), at depths of: 1365 to 1385 ft bgs; 970 to 990 ft bgs; 430 to 450 ft bgs; and 320 to 340 ft bgs. Laboratory test data show that the groundwater character was Ca-HCO_3 in the two shallower sampling zones, Ca-Na-HCO_3 in the 970 to 990 ft zone, and Na-Ca-HCO_3 in the deepest zone. TDS in the upper two zones were between 677 and 725 mg/l, whereas in the lower two sampled zones the TDS was 488 to 581 mg/l. Total hardness values showed that groundwater was very hard in the three upper zones (240 to 354 mg/l) but was only moderately hard in the deepest sampling zone (70 mg/l).

<u>Inorganic Constituents</u>

The TDS concentration of Saugus Formation groundwater typically ranges from 500 to 900 mg/l. The State Secondary MCL for TDS is expressed as a range with 500 mg/l set as the lower level whereas the upper level is set at 1000 mg/l. No fixed consumer acceptance contaminant level has been established for TDS.

Our firm recently re-examined available TDS data from Saugus Formation water wells in the Valley. For that effort, the original laboratory data from each well were used to re-calculate TDS using a more standard, additive method as described in a USGS report by Hem (1985). These data were then compared to historic pumping and water level records to look for possible trends in TDS concentrations over time, and to examine if these trends were related to changes in groundwater production.

The results of that evaluation revealed that although there has been a slight increase in TDS concentrations in most Saugus Formation wells in the past 40 years, this increase could not be correlated with increased groundwater production. Results indicate that TDS concentrations have actually decreased during periods of increased Saugus Formation groundwater production.

Final well blend sample results (where available) for Saugus Formation wells generally show iron and manganese levels below their State Secondary MCLs of 0.3 mg/l and 0.05 mg/l, respectively. The DHS drinking water database lists several analyses for Saugus Formation groundwater with iron levels above 0.3 mg/l and included values up to 1.8 mg/l, but these are likely caused by small amounts of suspended material in the samples, rather than actual dissolved iron.

Well blend samples, and a review of the DHS drinking water quality database, reveals that nitrate (as NO_3) concentrations in Saugus Formation groundwater are also below the Primary MCL of 45 mg/l for this constituent.

Organic Constituents

Organic chemicals generally have not been detected in Saugus Formation groundwater, with the exception of four Saugus Formation water wells in the eastern portion of the Valley. These wells include SCWC Saugus 1 and Saugus 2, NCWD-11 and VWC 157 (see Plate 5.1 for well locations). Trichloroethylene (TCE), an industrial solvent, has been detected at concentrations ranging from 0.5 to 3.8 μg/l in VWC 157 between 1998 and 2001. TCE has also been detected in concentrations ranging from 0.07 to 3.9 µg/l in SCWC Saugus 1, and from 0.07 to 1.3 µg/l in SCWC Saugus 2, between 1991 and 1997 when the two wells were put on inactive status.

None of the detected TCE concentrations in these wells was above its MCL of 5 µg/l for domestic use, and none of the three affected wells has been used for municipal-supply purposes since 1997.

Perchlorate

Perchlorate (ClO_4), and other related products, have also been detected in the same four wells, listed in the prior paragraph, that are located in the eastern part of the Saugus Formation. The current California DHS advisory action level for perchlorate is 4 µg/l. Testing of NCWD Well No. 11 showed perchlorate concentrations ranging between 9.9 and 23 µg/l between May 1997 and October 2000. This well is currently considered to be on inactive status, although NCWD has voluntarily refrained from using the well since 1998. Testing of VWC Well No. 157 between 1997 and 2000 showed perchlorate concentrations ranging from not detected (ND) to 14 µg/l. This well is also currently considered to be on inactive status, although VWC has voluntarily refrained from using the well since 1997. Finally, testing of SCWC Saugus No. 1 and Saugus No. 2 in 1997 and 1998 revealed perchlorate concentrations ranging from 16 to 42 µg/l in Well No. 1, and from 12 to 47 µg/l in Well No. 2. Neither of these two wells is currently being pumped, and both are on inactive status.

Results of ongoing laboratory testing of the remaining active Saugus Formation municipal-supply wells in the Valley have all shown non-detected concentrations of perchlorate. VWC Well Nos. 201 and 160 were sampled and analyzed for perchlorate in the third quarter of 2000, with the laboratory test data reporting not-detected results for both samples. Existing Saugus Formation water wells owned by NCWD were all tested for perchlorate in October 2000, with all samples returning not-detected results (with the exception of Well No. 11, discussed above).

Depth Discrete Aquifer Sampling

Until recently, little was known about the possible vertical variation in water quality in the Saugus Formation other than the presence of lower quality, higher salinity water in the stratigraphically lowermost portions of the formation (i.e., the Sunshine Ranch Member). However, depth specific water quality samples are now available for VWC Well 205 and NCWD Well 11.

As part of the 2000 ASR testing program, six discrete zones were sampled under pumping conditions within VWC 205, the details of which are summarized in Table 5.6 – Results of Depth-Discrete Sampling of VWC 205. The overall results generally agree with existing water chemistry data for the Saugus Formation. Specifically, the groundwater water has: a Ca-SO_4 to Na-SO_4 character; moderately high TDS (504 to 661 mg/l); low nitrate as NO_3 (4.78 to 8.6 mg/l); and moderately high iron (0.072 to 1.27 mg/l).

An interesting aspect of these VWC 205 laboratory results is the indication of a vertical chemical gradient within the upper 2000 ft of the Saugus Formation, with the concentration of virtually all dissolved constituents showing a generally consistent decrease with increasing depth of sampling (see Figure 5.3 – Plot of Water Quality vs. Depth, VWC 205). These new data appear to corroborate a similar improvement in water quality with depth that was observed in 1990 in a series of depth-discrete zone samples taken during construction of the Saugus Formation NCWD Well No. 13. It should be noted that VWC 205 penetrates only the upper one-third and geologically younger portion of the total Saugus Formation thickness at that site, and these results provide no information as to water quality in the older underlying beds near the base of the Saugus Formation.

Recent Aquifer Storage and Recovery (ASR) Testing

A preliminary program of aquifer storage (injection) and recovery testing by our firm, combined with groundwater modeling by CH2M Hill, were conducted in 2000-2001 as part of the Environmental Impact Report for the proposed Newhall Ranch development; the program was performed to examine the preliminary hydrogeologic feasibility of conducting an aquifer storage and recovery (ASR) program in the Saugus Formation. Details of the program are

RICHARD C. SLADE & ASSOCIATES LLC
CONSULTING GROUNDWATER GEOLOGISTS

FIGURE 5.3
Plot of Water Quality vs Depth
VWC 205

JOB NO. S9920 June 2002

contained in the report entitled Additional Analysis to the Newhall Ranch Specific Plan and Water Reclamation Plant Final Environmental Impact Report (2001), but the key points of that report are as follows:

1. It is hydrogeologically feasible to inject into and recover from the Saugus Formation significant volumes of water. The formation readily accepted water from the injection well, and subsequently yielded a comparable amount of water to the same well during pumping. Local mounding or depression of nearby static water levels (piezometric or pressure levels) due to injection or pumping, respectively, quickly returned to near pre-test levels once injection or pumping ceased.
2. An ASR program operated at annual injection rates of 4500 AF/yr during wet and normal years, and at annual extraction rates of 4100 AF/yr during dry years, was determined to have no significant negative effects on either the Valley, or on downstream users (i.e. Ventura County), as modeled by CH2M Hill (2001). The analysis predicted measurable benefits, including more rapid recovery of Saugus Formation water levels following drought periods.

An ASR project of a scope beyond that envisioned for the Newhall Ranch development may provide further benefits to the Saugus Formation aquifer system, particularly in light of the increased drought-year pumping levels outlined in the UWMP.

SECTION 6

CONCLUSIONS AND RECOMMENDATIONS

General Statement

The Santa Clarita Valley is has two local aquifer systems, the alluvial aquifer and the Saugus Formation aquifer. These important aquifer systems have provided and should be able to continue to provide reliable sources of potable drinking water for the area. Since the publication of the first significant hydrogeologic reports on these aquifer systems in the Slade 1986 Report and the Slade 1988 Report, respectively, significant new hydrogeologic data have been acquired and have greatly enhanced the understanding of the local groundwater sub-basin. Based on recent state-wide updating of groundwater basins in California, DWR currently is defining the local groundwater reservoir in the Valley as the Santa Clara River Valley East Groundwater Sub-basin. The western boundary at this sub-basin is currently taken at County line where it meets the adjoining (downstream) Piru sub-basin of Ventura County. The eastern boundary of the local groundwater sub-basin occurs at a narrows in the alluvium near Lang.

Based on our review of these new hydrogeologic data, we present the following conclusions and recommendations.

Hydrogeologic Conditions in the Alluvial Aquifer System

Extent and Thickness

The alluvial aquifer covers an area of approximately 16,000 acres on the floor of the main Santa Clara River Valley and its major tributary canyons. The aquifer is comprised by unconsolidated sand, gravel, silt and clay, and reaches a maximum thickness of 200 ft in local areas along the main reach of the Santa Clara River. In all canyons that are tributary to the main river, and as the lateral margins of the main river course and of the tributary canyons are reached, the thickness of the alluvium decreases. Groundwater occurs under unconfined (water table) conditions in the alluvial aquifer.

Water Levels

Water levels in the western portion of the alluvium (west of I-5) have historically been quite stable and insensitive to fluctuations in the amount of annual rainfall and surface water recharge. This is likely due, at least in part, to the upward flow of groundwater from the underlying Saugus Formation (particularly west of I-5), which provides a consistent source of recharge that is relatively independent of annual rainfall trends.

In addition, water levels in both the western portion and especially the central portion of the river valley (I-5 to Bouquet Canyon) have shown a progressive reduction in the amount of year-to-year variability, and a decreasing sensitivity to fluctuations in the amount of annual rainfall and recharge over the past ten years. This decreasing amount of annual water level fluctuation is due to the additional recharge provided to the alluvium from the annually increasing outflows (totaling 19,000 AF in 2000) from the two WRPs located between I-5 and Bouquet Canyon along the main river valley. The increase in WRP outflows and subsequent recharge of the alluvial aquifer system is directly related to the ongoing urbanization of the Valley and the concomitant and dramatic increase in the amounts of SWP water imported into the Valley since 1980. Imports of SWP water have risen from approximately 1,100 AF/yr in 1980 to over 32,000 AF/yr in 2000.

Water levels in wells along the main river valley east of Bouquet Canyon continue to display a much greater year-to-year variation, and a stronger correlation with changes in precipitation. In this reach of the river valley, water levels in alluvial wells decline temporarily during dry periods, but quickly recover to pre-drought levels once normal rainfall conditions return. This area is upstream from the two local WRPs, and is not influenced to the same degree by the increases in imported SWP water.

Overall, there is no evidence of a long-term, continuous or permanent decline in water levels in any alluvial aquifer well, and thus there is no evidence that the alluvial aquifer system is being pumped beyond its sustainable capacity. Whereas water levels in the alluvial aquifer do fluctuate over time, there is no continued and progressive decline in groundwater levels, leading to a permanent loss of groundwater in storage, which would be indicative of overdraft. There is clearly no overdraft in the alluvial aquifer system in the Valley.

Groundwater in Storage

As water levels in the alluvial aquifer fluctuate over time, so does the total quantity of groundwater in storage within this aquifer system. The alluvial aquifer contained an estimated 200,000 acre-feet of water in storage at its historical high in 1945. In the spring of 2000, the total volume of groundwater in storage in the alluvial aquifer was approximately 161,000 AF. Over time, groundwater levels and associated groundwater in storage in this aquifer system have fluctuated in response to wet and dry conditions in the Valley; this is particularly evident in the eastern portion of the alluvial aquifer. However, there has been no long-term, progressive decline in the amount of alluvial groundwater storage that could be considered indicative of overdraft conditions.

Groundwater Production and Operational Yield

Annual groundwater production from the alluvial aquifer by the major purveyors over the last ten years has averaged approximately 35,000 AF/yr, about 10 percent above the "practical or perennial yield" of 31,600 to 32,600 AF/yr calculated in the Slade 1986 Report. However, this recent increase in average annual production has occurred without any onset of undesirable conditions such as lowered water levels that might be indicative of excessive extractions or overdraft. The primary reason that the alluvial aquifer system has been able to supply groundwater for the past ten years in annual volumes that are well in excess of its previously estimated perennial yield is the greatly increased amount of water that has been imported into the Valley via the SWP since the early 1980s. Specifically, imports of SWP water into the Valley have risen from approximately 1,100 AF/yr in 1980 to over 32,000 AF/yr in 2000. Much of this additional water is returned to the alluvial aquifer system in the form of discharge from the two WRPs located along the Santa Clara River.

It is evident from observation of alluvial aquifer response to average pumping, and response to pumping in individual years, that the alluvial aquifer can be operated at a higher average pumping rate and over a wide range of yearly pumping rates without inducing undesirable conditions that would be indicative of overdraft, i.e., long-term continuous and progressive decline in water levels and storage. This observation is particularly evident since the initiation of supplemental SWP water deliveries in 1980. The ultimate goals of an increased operational yield for the alluvium would be to avoid both short-term adverse impacts as a result of year-to-year fluctuations in pumping, and to avoid long-term adverse impacts such as continuously lowered water levels and groundwater in storage in this aquifer system.

In summary, the combination of historical observations and current planning has led to the current conclusion that the alluvial aquifer system can be operated over a wide range of pumping rates, and on a long-term average basis it can be operated at an average pumping rate on the order of 10% higher than was reported as a "practical or perennial yield" in 1986. As summarized in the UWMP, the operational yield of the alluvial aquifer system will typically be in the 30,000 to 40,000 AF/yr range for most average and/or wet years, with expected reduction into the 30,000 to 35,000 AF/yr in dry year periods.

Groundwater Quality

Groundwater pumped by the local water purveyors is routinely sampled and tested by State-certified laboratories. These laboratory data show that the water quality of groundwater pumped from the alluvial aquifer system meets all current Federal and State drinking water standards.

Two important constituents in the groundwater in this aquifer system are nitrate and TDS. Nitrate concentrations in alluvial wells ranged from 14 mg/l in the easternmost alluvial wells, to 27 mg/l in alluvial wells near the confluence between the South Fork and main reach of the Santa Clara River. Nitrate concentrations in the area west of I-5 are quite low, with the concentration in five agricultural-supply wells in this area averaging just 6.6 mg/l. Nitrate concentrations in municipal-supply water wells within the alluvium are below its MCL of 45 mg/l for domestic use.

TDS generally increases from approximately 500 mg/l in the easternmost alluvial wells, to approximately 1000 mg/l in agricultural-supply wells west of I-5. All of the existing municipal-supply alluvial wells are located east of I-5.

VOCs, specifically 1,1,1-TCA and PCE, have occasionally been detected in a few municipal-supply wells in the eastern part of the Valley, but the detected concentrations of these VOCs have been consistently below their respective MCLs. The source(s) of these VOCs is not known and has not been investigated for this update report. No other alluvial municipal-supply wells have shown repeatable detections of any VOCs. There has also been no detection of perchlorate in any municipal-supply well constructed in the alluvial aquifer system in the Valley.

Groundwater extracted from the alluvial aquifer system by the municipal-supply water purveyors in the Valley has been and continues to be of acceptable quality for beneficial use.

Hydrogeologic Conditions in the Saugus Formation Aquifer System

Extent and Thickness

The Saugus Formation aquifer system is comprised by a deep bowl-shaped group of layered sediments having a surface outcrop area of approximately 55,500 acres. The formation is comprised of semi-consolidated sand, gravel, silt and clay, and reaches a maximum thickness beneath the central part of the Valley of approximately 8,000 ft. However, useable groundwater at this time is considered only to occur in the uppermost 2,500 ft of these sediments. Groundwater occurs under semi-confined to confined conditions within most of the formation; unconfined (water table) conditions may occur within some of the coarser-grained Saugus Formation strata exposed at or near ground surface in the hillsides surrounding the river valley.

The results of recent spinner surveys in selected Saugus Formation wells demonstrate that groundwater is being produced over the entire screened intervals in these tested wells, down to their maximum cased depths of approximately 2000 ft. Pumping tests (both step drawdown tests and constant rate tests) performed in the newer municipal-supply wells in this formation have been conducted at rates in the range of 1720 to 4000 gpm, and 2500 to 4000 gpm, respectively. Such rates document the high pumping rate capacity of this formation south of the San Gabriel fault.

Water Levels

Water levels (piezometric levels) in Saugus Formation water wells have typically fluctuated over time, with the magnitude of these historic fluctuations varying with each well; these annual fluctuations have generally ranged from a minimum of 50 ft to a maximum of 175 ft. It is important to note that these fluctuations are considered to be small because the Saugus Formation wells in which these fluctuations have occurred range in total cased depth from 750 ft to nearly 2000 ft. Furthermore, the depth to the top of the uppermost perforations in most existing Saugus Formation wells is typically 400 ft or more below ground surface.

Water levels in Saugus Formation wells appear to fluctuate in response to patterns of increasing or decreasing rainfall, and to some extent to patterns of increasing or decreasing groundwater extraction from the Saugus Formation. However, a significant observation from the hydrographs of wells constructed in the Saugus Formation is that no long-term or continuous decline in water levels has occurred in any Saugus Formation water well over time, thereby demonstrating that this aquifer system is not and has not been overdrafted.

Groundwater in Storage

The Slade 1988 Report calculated the volume of groundwater in storage in the Saugus Formation aquifer to be approximately 1.41 million AF. Groundwater in storage at that time was defined as that groundwater contained solely within with potential sand and gravel aquifer beds identified on e-logs, and only between the depths of 500 ft bgs and the shallower of either: a) a depth of 2500 ft bgs; b) the base of fresh water within the Saugus Formation; or c) the base of the Saugus Formation.

For this updated report, the volume of groundwater in storage in the Saugus Formation has been re-calculated using the same criteria used in 1988 except that the uppermost portion of the zone of interest within the formation has been raised from a depth of 500 ft to 300 ft bgs. This change is based on our increased knowledge of the thickness of the alluvial sediments in the Valley and the minimal degree of pumping interaction that was monitored between a pumping Saugus Formation well and a nearby alluvial groundwater monitoring well during the injection test program in 2000.

The current calculated volume of groundwater in storage in the Saugus Formation is approximately 1.65 million AF, or about 18% more than the 1988 calculation value. This increase is entirely due to raising the upper limit of the zone of storage from 500 ft to 300 ft bgs.

The actual volume of groundwater in storage in an aquifer can be less important than the amount of annual recharge to the aquifer for the purposes of determining the amount of water that can be withdrawn by pumping over the long term. However, when the volume in storage is particularly large in comparison to the amount of annual pumping, considerable flexibility is added to the available strategies for aquifer management. For example, the aquifer may be pumped heavily during dry years and then allowed to recover during wet years, either via natural or artificial recharge.

Groundwater Production and Operational Yield

Groundwater production from the Saugus Formation has averaged approximately 8,600 AF/yr from 1991 to 2000, whereas the maximum historical production volume was approximately 15,000 AF occurring in 1991, towards the end of a multi-year drought. No long-term continuous or permanent decline in either water levels or the amount of groundwater in storage has occurred under this historical range of pumping.

The operational yield concept includes flexibility of groundwater use by allowing increased pumping during dry periods and increased recharge (direct or in-lieu) with supplemental water when it is available in wet/normal periods. The operational yield protects the aquifer by helping to assure that groundwater supplies are adequately replenished on a long-term basis from one wet/dry cycle to the next. Limited historical data for the Saugus Formation show that no lowering of water levels or degradation of water quality has occurred in the area.

It is evident from observation of response to historical pumping from the Saugus Formation that this aquifer system can be operated (pumped) over a range of capacities to at least 15,000 AF/yr without causing undesirable conditions that would be indicative of "overdraft," i.e., a long-term continuous and progressive decline in water levels and in groundwater in storage. As a result, the operational yield of the Saugus Formation, or the yearly yield for operating purposes, could range up to an individual annual pumping volume on the order of 15,000 AF based on data available to date. As with the alluvial aquifer system, the ultimate goals of an increased operational yield for the Saugus Formation would be to avoid both short-term adverse impacts as a result of year-to-year fluctuations in pumping, and to avoid long-term adverse impacts such as continuously lowered water levels and storage.

In summary, the combination of historical observations and current planning has led to the current conclusion that the Saugus Formation aquifer system can be operated on a long-term average basis in the range of 7,500 to 15,000 AF/yr. Infrequently, during dry periods of one to three years, pumping operations can be ramped up from 15,000 to 25,000 AF/yr, and ultimately to 35,000 AF/yr if dry conditions continue. These latter increases would be temporary and would return to or below the historical range of 7,500 to 15,000 AF/yr once rainfall patterns returned to normal. As summarized in the UWMP, the operational yield of the Saugus Formation will typically be in the 7,500 to 15,000 AF/yr range for most year types, with possible short-term ramped increases in dry periods into the 15,000 to 35,000 AF/yr range. Such temporary and short-term increases above historic pumping are unlikely to have an adverse impact on the Saugus Formation aquifer system, and, in particular, are unlikely to induce a permanent loss of groundwater in storage. Any short-term water level decline or groundwater in storage decline is expected to be restored upon return to the historical operating range on an average annual basis.

Groundwater Quality

Groundwater pumped from the Saugus Formation aquifer system by the local water purveyors is routinely sampled and tested by State-certified laboratories. These laboratory data show that the water quality of pumped groundwater down to the existing known maximum depth of these wells (2000 ft) meets all current Federal and State drinking water standards. Aquifer zone isolation testing performed in individual aquifer units during the drilling of selected Saugus Formation wells further corroborates that water quality to depths of at least 1530 ft bgs is suitable for municipal-supply purposes.

Groundwater character within the Saugus Formation generally varies from calcium-bicarbonate in the area along the South Fork of the Santa Clara River, to calcium-sulfate towards the deeper central parts of the local groundwater sub-basin.

An important water quality parameter in Saugus Formation groundwater is its TDS concentration. TDS concentrations of Saugus Formation groundwater typically range from 500 to 900 mg/l. The State Secondary MCL for TDS for domestic use is expressed as a range, with the upper value for TDS being 1000 mg/l. No fixed consumer acceptance level has been established for TDS.

A detailed re-calculation and review of available historic TDS data from Saugus Formation water wells has been performed and revealed that although there has been a slight increase in TDS levels in most Saugus Formation wells in the past 40 years, this increase can not be correlated with increased groundwater production. In fact, there is evidence that TDS concentrations have actually decreased during periods of increased Saugus Formation groundwater production.

Recent depth specific sampling of several Saugus Formation wells under pumping conditions indicates that groundwater quality, as determined by the quantities of certain dissolved inorganic constituents, actually improves slightly with depth in the upper 2,000 ft of the formation.

Perchlorate

Perchlorate (ClO_4), a component of rocket fuel, has been detected at concentrations ranging from approximately 10 to 47 µg/l in four wells (SCWC Saugus Nos. 1 and 2, NCWD-11 and VWC-157) in the eastern part of the outcrop area of the Saugus Formation. The current California DHS advisory action level for perchlorate is 4 µg/l. Each of these four wells was taken out of service following the initial detection of perchlorate in 1997.

Results of ongoing laboratory testing of the remaining active Saugus Formation municipal-supply wells have all shown perchlorate to be not detected. VWC Well Nos. 201 and 160 were sampled and analyzed for perchlorate in the third quarter of 2000, with the laboratory test data showing not-detected results for both samples. The other active Saugus Formation water wells owned by NCWD were all tested for perchlorate in October 2000, with all samples also revealing not-detected results.

Perchlorate in the Saugus Formation groundwater is currently known to affect only the eastern portion of the Saugus Formation aquifer system. The local water purveyors are currently investigating a treatment program using an existing and approved technology to restore the water supply capacity of the four impacted wells, and to assist in remediating and containing the groundwater contaminated by perchlorate. The California Department of Toxic Substances Control is overseeing the ongoing remediation and cleanup of a suspected source of this (and related) contaminants. All other existing Saugus Formation municipal-supply production wells are unaffected by perchlorate and this aquifer system remains a viable source of groundwater for the Valley.

Future Well Construction

Alluvial Aquifer System

It is considered hydrogeologically feasible to site, drill and construct new municipal-supply water wells within the alluvial aquifer system in the Valley. These new wells, specifically designed and constructed for municipal-supply purposes, should gradually replace those older existing municipal-supply wells that were originally constructed for agricultural-supply purposes. Additional new well construction may also occur as urbanization of the Valley continues and the groundwater currently pumped by existing agricultural-supply wells is designated for municipal-supply purposes.

The site-specific siting and design of new individual alluvial aquifer wells is beyond the scope of this report, but the following points summarize some key siting and design considerations for those new municipal-supply wells:

- New wells should be properly designed, constructed, developed and tested, and then equipped with water level transducers, if appropriate, for ongoing water level monitoring.
- Lateral separation between future and existing municipal-supply wells, and between those wells and existing privately-owned domestic wells, should be carefully selected to minimize the potential for water level drawdown interference.
- New municipal-supply wells should be constructed with relatively deep perforated intervals, and sufficiently deep cement sanitary seals to reduce the potential for inflow of surface water and/or shallow, poor-quality groundwater.
- New wells should be drilled and completed only within the alluvial aquifer to avoid the unplanned cross-flow of water between the alluvial aquifer, and confined portions of the underlying Saugus Formation.
- Proposed well sites should be evaluated for possible sources of past or present groundwater contamination. This will be particularly important as the urbanization of the Valley continues.

- Siting studies for new municipal-supply alluvial wells should include a field reconnaissance and well canvass to determine whether or not there are any nearby wells owned by others that might lie within the cone of water level depression created by future pumping of each newly proposed municipal-supply water well.

Saugus Formation Aquifer System

It is considered to be hydrogeologically feasible to site, drill and construct new municipal supply water wells in the Saugus Formation aquifer system. New Saugus Formation water wells will be needed to provide the increased Saugus Formation groundwater production envisioned by the 2000 UWMP. In anticipation of this new well construction, we have reviewed the construction details and well performance characteristics of existing Saugus Formation water wells in light of recent advances in our understanding of the geology and hydrogeology of the Saugus Formation. This has led to the development of several criteria for identifying areas that are hydrogeologically favorable for the drilling and construction of new Saugus Formation water wells. These criteria include:

1. New wells should be located in areas where the total thickness of potential Saugus Formation sand and gravel units in the depth range of 300 ft to 2500 ft bgs is generally greater than 800 ft (refer to the locations of such areas on Plate 3.2). This criterion will help maximize the total thickness and number of potential coarse-grained aquifer units intersected during drilling of the pilot hole for the new well. Because of the "bowl-shaped" structure of the Saugus Formation in the Valley, areas of thickest potential sand and gravel aquifers are found nearer the center of the basin, especially in areas adjacent to the Holser fault, within the southern and central fault blocks.
2. New wells should be located in areas where the depth to the top of the Santa Clarita Aquifer Zone beneath the potential well site is at least 800 ft below ground surface. This is because the more productive of the existing Saugus Formation water wells tend to intersect the Santa Clarita Aquifer Zone at depths of 1000 ft or more.
3. Extrapolation of the results of recent aquifer testing carried out on VWC Well Nos. 205 and 201 has been used to provide a reasonable approximation of potential drawdown interference between new and nearby existing Saugus Formation municipal-supply water wells. New wells should be located in areas that will provide a minimum separation of 1000 ft from existing Saugus Formation municipal- or agricultural-supply water wells; this is important to help minimize the potential for mutual water level drawdown interference between pumping municipal-supply wells.

4. Siting studies for the new municipal-supply wells in this formation should include a field reconnaissance and well canvass to determine whether or not there are any nearby wells owned by others that might lie within the cone of water level depression created by future pumping of each newly proposed municipal-supply water well.

The depth to the base of fresh water as calculated from e-logs has also been used as a criterion in evaluating these recommended drilling areas. In the recommended areas presented herein, the depth to the base of fresh water was found to be greatly in excess of the anticipated depth range of 1500 to 2000 ft for new Saugus Formation water wells.

At the present time, it is not known if the San Gabriel and/or Holser faults act as barriers to groundwater flow within the Saugus Formation, particularly in the area west of Bouquet Junction. Recent groundwater modeling by CH2M Hill (Newhall Ranch ASR Impact Evaluation, 2001) suggests that the faults do not act as groundwater barriers, but there is currently no way to test this hypothesis due to a complete absence of deep, Saugus Formation water wells north of the faults. The issue is further complicated by the fact that there is not a consensus among geologists as to the position, or even the existence of the Holser fault where it is projected beneath alluvium in the main river valley.

Given the present lack of hydrogeologic information regarding the San Gabriel and Holser faults, we suggest that new Saugus Formation wells avoid being located near mapped traces of the two faults in order to minimize the potential for increased water level drawdown that might occur if the faults were barriers to groundwater flow.

Plate 6.1 – Recommended Areas for New Saugus Formation Water Wells - illustrates a large area in the central portion of the Saugus Formation outcrop area that meets the above hydrogeological and logistical criteria. The favorable areas identified at this time occur within the central and southern fault blocks. Circular buffer zones are shown around existing wells to identify minimum separation zones covered by criteria 3, 4 and 5 above.

The area shown in Plate 6.1 is intended only as a general guide to prospective drilling areas. Each specific future well site should still undergo a detailed evaluation of its unique subsurface geology, geologic structure, site logistics and position relative to existing or planned infrastructure.

When evaluating potential sites for new Saugus Formation water wells, the following site logistics criteria should also be considered:

- Sufficient room to maintain required setbacks from nearby sewers and storm drains.
- Sufficient room for drilling and testing equipment.
- Possible presence of overhead obstructions such as trees or aboveground utilities.
- Availability of water for drilling, from either a nearby hydrant or an existing water well, or from a nearby water transmission line.
- Proximity to nearby residences or other structures for which there could be the potential need for noise abatement procedures and equipment.
- Sufficient room for temporary water storage tanks and an available discharge point for releasing water produced during drilling, development and testing of a new well, to permit conformance with NPDES requirements.

Artificial Recharge

<u>Alluvial Aquifer System</u>

Artificial recharge is the process of augmenting the natural recharge to the aquifer, a process that normally occurs on an ongoing basis via the natural infiltration of precipitation and surface water runoff. Artificial recharge programs utilize a variety of man-made works that are designed to maintain infiltration rates, increase the surface area over which infiltration takes place, and increase the length of time during which infiltration can occur. Regardless of the exact method used, the goals of an artificial recharge program typically include:

- Replenishing or increasing the amount of groundwater in storage in the aquifer.
- Storing water in times of low demand for subsequent use in high demand periods.
- Increasing the infiltration of surface water runoff, particularly during flood flow periods.
- Increasing the flexibility of the operating and management plans of local water purveyors.

Of the numerous methods available for artificial recharge, the most appropriate to the water table conditions in the alluvial aquifer would be a system of surface spreading basins or off-stream basins, or similar structures. This would involve the construction of basins or impoundments to store water from one or more available sources, and permit the infiltration of the water into the underlying alluvial aquifer.

Plate 6.2 – Potential Areas for Artificial Recharge, Alluvial Aquifer – illustrates the areas within the main river valley upstream (east) of Bouquet Canyon where the Slade 1986 Report suggested artificial recharge could potentially be carried out by means of surface spreading basins. Those areas were chosen for their potentially relatively high rates of vertical infiltration of water through the local soils (generally greater than 6 inches per hour), and the possible absence of low-permeability clay layers in the uppermost 25 ft of alluvial sediments. In addition, local surface water quality constraints and the quality of the local alluvial groundwater at that time were also considered.

Even in areas that may be otherwise suitable for artificial recharge, high (shallow) water levels may limit the amount of available (extra) storage capacity in the aquifer. The limited amount of water level fluctuations seen on hydrographs for wells in the western and central portions of the alluvial aquifer suggests that the aquifer is essentially "full" or nearly "full" in these areas, and thus the aquifer system in those portions of the Valley would tend to have little or no available capacity to receive and store additional water from a nearby artificial recharge program. It is probable that only in those areas along or near the Santa Clara River east of Bouquet Canyon are groundwater levels sufficiently below their likely maximum levels to provide available storage capacity that could be filled by artificial recharge on a regular basis.

Detailed investigations of potential recharge sites have not been performed to date. The Slade 1986 Report discusses the general types of additional work required to evaluate individual sites in greater detail, as well as some potential problems associated with artificial recharge of the alluvium.

<u>Saugus Formation Aquifer System</u>

Because the Saugus Formation is predominantly a semi-confined to confined aquifer with lower permeability and transmissivity than the alluvial aquifer, artificial recharge of the Saugus Formation via spreading basins would not be practical. However, recent field testing and groundwater modeling have demonstrated that ASR using deep injection wells is both feasible and potentially advantageous for the Saugus Formation.

An ASR project of a scope beyond that envisioned for the Newhall Ranch development may provide further benefits to the Saugus Formation aquifer, including:

- Increased volume of groundwater in storage in the aquifer.
- More rapid post-drought recovery of Saugus Formation water levels.
- Possible improvement in the groundwater quality in the Saugus Formation, depending on the source of the injection water.
- Greater flexibility in the operations and management being performed by the local water purveyors.

Conjunctive Use and Management of the Alluvial and Saugus Formation Aquifers

Conjunctive use refers to the coordinated management and operation of multiple water supplies to achieve improved reliability of the water supply. In this aspect, the Valley is fortunate to have two local aquifers that can be conjunctively used with imported SWP water in order to provide the Valley with a reliable supply of potable drinking water.

Since beginning to import a supplemental surface water supply in 1980, the Santa Clarita Valley Water Purveyors have been conjunctively utilizing that imported surface water with local groundwater from the alluvial and Saugus Formation aquifer systems. It has been conjunctive use that has allowed increasing water demands to be met while maintaining groundwater production within a range that precludes either aquifer system from being in overdraft. A similar, but expanded, conjunctive use program, as described in detail in the recently adopted UWMP, is expected to integrate additional supplemental sources of water supply in order to meet further projected increases in water demand while maintaining both aquifer systems within long-term sustainable yield, i.e. no overdraft.

As projected increases in water demand are experienced in the future, it is anticipated that pumpage from the alluvial and Saugus Formation aquifer systems will remain, on a long-term basis, in the same range as in recent years. Increasing water demands will be met by increased imported supplies, recycled water, demand-side management (conservation), and other sources to be developed.

Future conjunctive use operations are expected to entail some short-term increased pumping from the Saugus Formation during dry periods and reduced SWP water availability. While that pumping could increase into a range of 15,000 to 35,000 AF/yr for one to three consecutive dry years, surface water will be conjunctively used in greater amounts during wet and normal years to allow Saugus Formation pumpage to decrease such that, again on a long-term basis, pumpage is maintained within historic range; overdraft would be avoided. Such future conjunctive use may also include some purposeful injection of water into the Saugus Formation to enhance the recovery of water levels and also to increase the amount of groundwater in storage following periods of higher pumping during dry periods.

A conjunctive use strategy for the Valley could include:

- Utilizing a combination of imported SWP water and increased groundwater pumpage from the alluvial aquifer system during periods of average or above average rainfall (normal and wet years).
- Utilizing increased extraction from the Saugus Formation during periods of lower than average rainfall in the Valley (dry years), or during periods of decreased availability of water from the SWP.
- Enhancing the recovery of water levels and the volume of groundwater in storage in the Saugus Formation through a program of artificial recharge, via injection, whenever additional water supplies are available.
- Increasing the available storage capacity of the alluvial aquifer through increased pumping in the area east of Bouquet Canyon. This would serve to enhance both the natural recharge to the aquifer, and the effectiveness of an artificial recharge program using surface spreading basins in the same area.
- Augmenting the natural recharge to the alluvial aquifer system through the use of spreading basins or similar structures along the river in the area east of Bouquet Canyon.

Groundwater Monitoring

General Statement

During the preparation of this report, a significant effort was made to research, collect, and verify current and historic data on groundwater levels and water quality, on water well locations and construction details, and on aquifer parameters, for both the alluvial and Saugus Formation aquifer systems. A large component of this effort was the construction of a GIS database that not only serves as a repository and analytical tool for historic data, but which should be used as the basis for any future monitoring program. This data collection effort and database creation are now expected to evolve into a formal program of monitoring, data collection, and database maintenance, with standardized procedures for data collection and a central, single repository for the data.

In addition, an effort should be made to fill in existing data gaps by collecting data from existing private wells, agricultural-supply wells, or piezometers (where possible), or, where practical, by drilling and constructing a limited number of new monitoring wells in both aquifer systems in the Valley.

Selection of Monitoring Sites

A specific site for the collection of water quality data is not necessarily a suitable site for the measurement of water level data in an aquifer, and therefore data collection efforts for these two types of data need not be conducted at the same monitoring sites. For example, an active, properly constructed production water well is an excellent location for the collection of water quality samples. However, water levels measured in this same active production well may be strongly affected by incomplete recovery or by pumping water level drawdown in the vicinity of the well, and hence the collected water level data may not be representative of conditions in that portion of the aquifer as a whole. This is particularly true for wells that are not currently equipped with pressure transducers, and that are pumped almost continuously during periods of heavy water demand (e.g. the NCWD Saugus Formation wells). For an existing well to be used in the monitoring program, it will also be necessary to verify that pertinent well construction data exist or can be obtained via a video survey in the well.

Each well selected for water level monitoring should have a permanent reference point marked on the wellhead, and the elevation of each reference point should be accurately determined using either traditional survey methods tied to a benchmark of known elevation, or a survey-grade differential GPS unit. All vertical elevations should be tied to a single, widely used vertical datum.

Alluvial Aquifer System

Given that water levels are used to determine changes in the amount of groundwater in storage, a practical approach to selecting sites for water level monitoring in the alluvial aquifer may be to choose at least one monitoring site in each of the alluvial storage subunits described in Section 4. This would permit a more accurate and reliable determination of the year-to-year variation in groundwater in storage in the alluvium.

It may also be very useful to establish a series of monitoring wells near the downstream end of the alluvial aquifer between Castaic Junction and County Line. This could help to quantify the amount of subsurface outflow within the alluvium, and to assist in groundwater model calibration and groundwater basin management efforts.

Terrace Deposits

Terrace deposits are not considered to be a viable water-bearing aquifer unit because they are generally situated above the regional water table. In addition, surface exposures of these terrace deposits are not considered to be either areally extensive or thick. Hence, establishment of a groundwater monitoring program for these deposits is not recommended.

Saugus Formation Aquifer System

Monitoring of water levels and water quality within the Saugus Formation will likely be restricted to existing and/or newly constructed Saugus Formation water-supply wells for the foreseeable future, given the high cost of constructing deep monitoring wells in this aquifer system. However, a program of regular monitoring of both water levels and (where possible) water quality in existing wells, both active and inactive, would add to the ever-increasing database on the Saugus Formation.

If monitoring wells are to be constructed, careful consideration should be given to areas within the outcrop area of the Saugus Formation where data are lacking, or where the data would be particularly useful for groundwater model calibration purposes. Areas where data are particularly lacking include the area between the Holser and San Gabriel faults, and the area north of the San Gabriel fault. Both the siting and the design of new monitoring wells should be undertaken with these considerations in mind.

Another step that could be taken to enhance the current understanding of Saugus Formation water levels and water quality would be to include several of the existing privately-owned Saugus Formation wells (e.g. the Poe and Anden wells, and NLF-156) in the ongoing monitoring program. These wells are located in key areas in the Saugus Formation where no nearby municipal-supply wells exist.

Network Operation and Monitoring

Data collected should include:

- Static and pumping water levels in both the alluvial and Saugus Formation aquifer systems.
- Water quality data for both aquifers and for the Santa Clara River and its major tributaries.
- Annual groundwater extraction volumes pumped by individual wells from all of the major water users, including private and agricultural users.
- Detailed well construction information for new and existing wells.
- Records of any well destruction activities, including the dates and methods used.
- Historic data on aquifer parameters, as well as newer data acquired during new well construction and testing.
- A well canvass to better define the locations and annual production from privately-owned, domestic-type water wells in both aquifer systems.
- Information on potential groundwater contamination sites obtained from available government and/or private databases and publications.
- Discharge volume and water quality data for existing and future WRPs.
- Rainfall records.
- The amounts, rates, locations, and water quality for any water that is recharged into the two local aquifer systems in the future.

- Other relevant data, such as major changes in land use, and annual variations in the volume of water imported to the Valley.

A series of standardized procedures for collecting, recording, verifying and reporting of the data should be established and implemented on a regular basis. All records collected by the coordinating entity should be stored in a relational database and integrated with a GIS system.

The measurement and recording of water level data should be done, where feasible, via recording pressure transducers, with periodic manual measurements to provide confirmation. This will provide a continuous record that is considerably more useful than infrequent manual measurements for monitoring water level conditions in the Valley. Transducers not only provide a much more complete and accurate water level record, but may also be more cost effective and reliable than a program relying strictly on manual measurements.

Executive Summary

This Interim Remedial Action Plan (IRAP) is submitted to the California Environmental Protection Agency Department of Toxic Substances Control (DTSC) by the Castaic Lake Water Agency, Newhall County Water District, Santa Clarita Water Company and Valencia Water Company (collectively, the Water Purveyors). The IRAP is prepared in accordance with Section 25356.1 of the California Health and Safety Code and is submitted in accordance with Task 4 of the Environmental Oversight Agreement executed by DTSC and the Water Purveyors in March 2003. The evaluations summarized in this IRAP are consistent with the requirements of the National Oil and Hazardous Substances Pollution Contingency Plan (NCP).

This IRAP addresses four Saugus Formation water supply production wells that have been impacted by perchlorate. These production wells are located along the South Fork of the Santa Clara river, west of the former Whittaker-Bermite site (the Facility). A fundamental objective, incorporated into the alternatives, is to provide containment of Saugus Formation groundwater west of the Facility that is impacted by perchlorate.

Remedial Investigation

For approximately fifty years ending in 1987, the Facility was used for the manufacturing, storage, and testing of a variety of explosives, munitions, and propellants. Subsurface characterization activities performed since that time have documented that soil and/or groundwater in various portions of the Facility have been impacted by releases of perchlorate, volatile organic compounds and other chemicals. In accordance with DTSC requirements, Whittaker Corporation (Whittaker) is continuing to perform soil and groundwater characterization activities within and near the boundaries of the Facility.

Assessment of the extent of Saugus Formation groundwater impacted by perchlorate relies on subsurface characterization activities performed to date in the area designated as Operable Unit 7 (OU7). The most recent of the subsurface characterization tasks was performed by the US Army Corps of Engineers and its consultant CH2MHILL. The remedial investigation activities completed west of the Facility are sufficient to proceed with evaluation and implementation of a measure to partially restore lost production capacity and contain Saugus Formation groundwater impacted by perchlorate.

Human Health Risk Assessment

Evaluation of potential risks to human health, as summarized in this IRAP, indicates that groundwater containing perchlorate should be treated prior to human consumption to reduce perchlorate concentrations to less than 6 micrograms per liter (µg/l) and/or as necessary to comply with the California Department of Health Services Policy for Extremely Impaired Water Bodies (DHS Policy 97-005) and the State Water Resources Control Board Non-Degradation Policy.

Moreover, because implementation of the preferred remedial alternative will not fully restore the water production capacity that was lost due to contamination, construction of replacement water supply wells and associated infrastructure is anticipated. The infrastructure associated strictly with capacity replacement is outside the scope of this IRAP and is not evaluated herein, but it is nevertheless an important component of the resolution of outstanding issues between Whittaker and the Water Purveyors.

Section 1: Introduction

This Interim Remedial Action Plan (IRAP) is submitted on behalf of Castaic Lake Water Agency (CLWA), Newhall County Water District (NCWD), Santa Clarita Water Company (SCWC), and Valencia Water Company (VWC) (Water Purveyors). The IRAP is prepared in accordance with Section 25356.1 of the California Health and Safety Code and is submitted to the California Environmental Protection Agency Department of Toxic Substances Control (DTSC) in accordance with Task 4 of the Environmental Oversight Agreement executed by DTSC and the Water Purveyors in March 2003. The evaluations summarized in this IRAP are consistent with the requirements of the National Oil and Hazardous Substances Pollution Contingency Plan (NCP).

The Water Purveyors operate groundwater production wells and provide water to approximately 50,000 connections in the Santa Clarita Valley in northern Los Angeles County. The project location is shown on Figure 1. Historically, groundwater from the Saugus Formation production wells has been used as an ongoing water source to blend with State Water Project (SWP) water deliveries and a water bank to compensate for SWP water curtailments. Perchlorate contamination of a portion of the Quaternary alluvium and Saugus Formation has rendered five groundwater production wells, with a combined capacity of 8,700 gallons per minute, unusable because the concentration of perchlorate detected in samples from the production wells has been in excess of the notification level (through 2004 referred to as the action level) established by the California Department of Health Services (DHS). The Whittaker-Bermite Facility (Facility), which had documented releases of perchlorate and other hazardous materials to the environment, is located generally upgradient of these production wells.

Perchlorate associated with the releases of hazardous substances to soil and groundwater at the Facility was detected in water samples from four Saugus Formation groundwater production wells in 1997. In response to the detected concentrations of perchlorate, these wells were removed from service. Perchlorate associated with the release of hazardous substances at the Facility was subsequently detected in a sample from an alluvial groundwater production well, which was removed from service in 2002. Prior to their removal from service, these five wells were essential sources of local water supply, particularly when other water supplies were reduced, such as in drought years.

The Water Purveyors are responsible for maintaining an adequate and reliable water supply for the residential and business communities in Santa Clarita, as well as for balancing water quality within different portions of the distribution system and between water supply sources. The Water Purveyors have considered several approaches for restoration of the groundwater production capacity that was lost due to impact by perchlorate. The general approaches include: importing additional water from the State Water Project; installation of replacement water supply wells outside the area currently impacted by perchlorate, with associated water distribution pipelines to return water to the service areas served by the perchlorate-impacted wells; and utilizing treatment to return the perchlorate-impacted wells to service for community water supply.

In considering these general approaches, the Water Purveyors determined that restoring groundwater pumping along the South Fork of the Santa Clarita River, where the perchlorate-impacted Saugus Formation production wells are located, is critical to protect downgradient water wells – Santa Clarita Water Company's Saugus Well No. 1 (Saugus 1) and Saugus Well No. 2 (Saugus 2), Newhall County Water District's Well No. 11 (NC-11), and Valencia Water Company's Well No. 157 (VWC-157) at their maximum pumping capacity. The locations of these wells are shown on Figure 2.

In addition, where practicable, this IRAP is concerned with adjacent areas of the Saugus Formation as well as portions of the overlying alluvium where the Santa Clarita Water Company's Stadium Well (Stadium Well) and Valencia Water Company's Well Q-2 have been impacted by perchlorate and continued migration of perchlorate could further impact the water supply within the capture zone of these four existing Saugus Formation domestic-supply water wells. However, remedial plans for addressing impacts to the Stadium Well and Well Q-2 have not been included in this IRAP. The Stadium Well is located generally downgradient from the northern portion of the Facility where elevated levels of perchlorate have been detected in soil and groundwater samples. Operation of the Stadium Well will be evaluated following completion of source area characterization activities and implementation of source area remedial measures by the Whittaker Corporation (Whittaker). Additional subsurface characterization in the vicinity of the Stadium Well was identified as a priority subtask for Operable Unit 7 (OU7) in a letter from DTSC to Whittaker representatives dated 10 March 2003. As noted above, a perchlorate treatment system for Well Q-2 is expected to be operational by the fall of 2005.

It should be noted that the Santa Clarita Water Company was acquired by CLWA, and is now known as the Santa Clarita Water Division of CLWA. However, for the purposes of this document, it will be referred to as the Santa Clarita Water Company.

As noted above, although five production wells with an aggregate production capacity of 8,700 gpm have been impacted by perchlorate, this IRAP addresses restoration of only a portion of the lost production capacity. The Water Purveyors intend to restore the remaining portion of the lost production capacity through installation of replacement wells outside the area of groundwater impacted by perchlorate and outside the scope of this IRAP which addresses remediation of perchlorate-impacted groundwater.

22116 West Soledad Canyon Road, Santa Clarita, California. The Facility is approximately 996 acres and is located to the east of the five production wells impacted by perchlorate and the South Fork of the Santa Clara River (South Fork, Figure 2).

From 1934 to 1987, the Facility was used for the manufacturing, storage, and testing of a variety of explosives, munitions, and propellants (Hargis 1999). Materials that were used in activities at the Facility include, but are not limited to: ammonium perchlorate, potassium perchlorate, hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX), octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine (HMX), methyl ethyl ketone (MEK), and chlorinated solvents such as trichloroethene (TCE) and tetrachloroethene (PCE). Depleted uranium may also have been used at the Facility (CH2MHILL 2005).

At this time, subsurface characterization and localized soil remediation activities are being performed at several locations within the perimeter of the Facility to address elevated concentrations of perchlorate and several VOCs in soil and/or groundwater. These activities have been described and the resulting data presented in a series of reports prepared by representatives of Whittaker and Remediation Financial, Inc. as directed by the DTSC. Summary of this information is not within the scope of this IRAP, however, it should be noted that the data indicate that releases of perchlorate and VOCs to soil and/or groundwater occurred within the Facility.

2.1.4 Presence of Perchlorate

Perchlorate is an anion that results from the dissolution in water from ammonium, potassium, magnesium or sodium salts. Ammonium perchlorate is used as the primary ingredient in propellants for rockets, missiles and fireworks. The perchlorate anion is extremely soluble and mobile in surface water and groundwater.

In mid-1997, perchlorate was detected in the four production wells previously described (Saugus 1, Saugus 2, NC-11, and VWC-157) which are located along the South Fork. The wells withdrew groundwater from the Saugus Formation for domestic water supply. At that time, perchlorate was detected at concentrations near or in excess of the DHS action level of 18 micrograms per liter (µg/l). Following the detection of perchlorate, the production wells were shut down. In January 2002, DHS reduced the action level for perchlorate from 18 to 4 µg/l (DHS 2002a). Perchlorate was subsequently detected in the alluvial aquifer production well, Stadium Well, located near the main reach of the Santa Clara River, at a concentration as high as 5.9 µg/l. Following the detection of perchlorate, the Stadium Well was shut down. In March 2004, DHS established the Public Health Goal and action level for perchlorate at 6 µg/l. The combined production capacity of the five production wells that were shut down due to the presence of perchlorate is 8,700 gpm. In early 2005, during a very wet winter, perchlorate was detected in samples from Well Q-2.

2.2.5 Hydrogeology

The impacted water supply wells are located within the Santa Clara-Calleguas Hydrologic Unit, which includes the Santa Clara River watershed. Within the Santa Clara-Calleguas Hydrologic Unit, the wells are located within the Upper Santa Clara River Hydrologic Area and in the Eastern Hydrologic Subarea (Hargis 1999). The wells are located in the Santa Clara River Valley East Groundwater Sub-Basin, as described above (RCS 2002).

Lithologic units in the area of the four production wells have been generally grouped into water-bearing and nonwater-bearing formations, based on their ability to store, transmit, and yield groundwater (RCS 2002). Water-bearing units include the Quaternary alluvium and the Saugus Formation. Non water-bearing units include Tertiary sedimentary rocks of the Pico Formation, older igneous and metamorphic rocks of the San Gabriel Mountains, and Miocene-age terrestrial sediments of the Tick and Mint Canyon Formations.

Alluvium:
The Quaternary alluvium consists of sand, gravel, and boulders within the Santa Clara River channel, grading to finer flood plain deposits at the valley margins. Quaternary alluvium deposits are up to approximately 200 feet thick in the Santa Clara River Valley (RCS 2002). Transmissivity values calculated for the Quaternary alluvium in the Santa Clara River channel and floodplain range from 81,000 gallons per day per foot (gpd/ft) to 750,000 gpd/ft (RCS 2002).

Groundwater in the alluvium occurs under unconfined conditions, with groundwater flowing from east to west along the main river valley. The alluvium in the main river valley east of Interstate Highway 5 (I-5) is recharged primarily by infiltration through the bed of the Santa Clara River and discharges to the Saugus Formation through deep percolation, whereas west of I-5, groundwater in the alluvium is recharged by upward flow from the underlying Saugus Formation and discharges to the river. Along the South Fork, the groundwater flow direction is generally to the north and the alluvium is recharged by infiltration of stream runoff from the river (when flowing) (RCS 2002).

Terrace Deposits:
Pleistocene terrace deposits in the vicinity of the Saugus Formation domestic water production wells are not likely to exceed approximately 200 feet in thickness and are generally restricted to uplifted terrace platforms that are topographically higher than the Santa Clara River. Perched groundwater may be present locally (RCS 2002).

Saugus Formation:
The Saugus Formation consists of semiconsolidated sandstone, siltstone, and conglomerate up to 8,500 feet thick (RCS 2002). The Saugus Formation represents a significant reservoir for groundwater storage as it underlies the Santa Clara River Valley at a considerable thickness (Hargis 1999). In the vicinity of the Saugus Formation domestic water production wells, hydraulic conductivity values calculated for the Saugus Formation have historically ranged from 44,000 gpd/ft to 182,000 gpd/ft (RCS 2002).

Groundwater in the Saugus Formation exists under confined, semi-confined, and unconfined conditions, primarily within interstitial voids resulting from primary porosity. In some areas, particularly near its eastern and western margins, the Saugus Formation is in hydraulic communication with the overlying Quaternary alluvium along the channel of the Santa Clara

2.3 Regulatory Framework

The California Department of Toxic Substances Control (DTSC) is the lead regulatory agency overseeing the remedial actions and has determined that Santa Clarita LLC and Whittaker are responsible parties at the Facility. DTSC has entered into an Enforceable Agreement with Santa Clarita LLC and Whittaker, dated February 2001, however Santa Clarita LLC has defaulted on its obligations under the Enforceable Agreement and DTSC has subsequently issued an Imminent and Substantial Endangerment Determination and Order and Remedial Action Order, dated November 2002, to Whittaker.

The Facility and surrounding area containing impacted groundwater have been divided into seven operable units (OUs) based on the location of known source areas, former Facility operations, local surface watersheds, and the affected media (DTSC 2001). For the purposes of subsurface characterization and remediation, the Facility has been divided into six soil OUs; OU1 through OU6. Whittaker is currently performing subsurface investigation activities and will be evaluating remedial alternatives for these OUs within the Facility. OU7 encompasses onsite and offsite areas where groundwater has been impacted by chemicals released from former Facility operations, including the five impacted production wells. The remedial investigation activities, risk assessment, and alternatives evaluation summarized in this IRAP apply to a portion of OU7 located west of the San Gabriel Fault, but are intended to be consistent with future remedial actions to be performed by Whittaker.

DTSC and the Water Purveyors have entered into an Environmental Oversight Agreement, dated March 2003, pursuant to H&SC Section 25201.9, whereby DTSC may provide consultative services and assistance to the Water Purveyors in complying with regulatory requirements. Under this agreement, DTSC will provide oversight of the actions undertaken by the Water Purveyors to respond to the perchlorate contamination in the vicinity of the impacted domestic water production wells within OU7.

Additionally, other agencies may have specific requirements that must be met based on the particular alternative implemented. Other regulatory agencies with significant oversight authority include the California DHS and the Regional Water Quality Control Board (RWQCB). DHS Policy Memo 97-005 is applicable to the production wells impacted by perchlorate, both on the basis of detected perchlorate concentrations in samples from the wells and due to their location downgradient of a known source of contamination. DHS will require treatment of the groundwater prior to its use for community water supply purposes. Furthermore, returning the perchlorate-impacted production wells to service for community water supply will require submitting a permit application package and obtaining a permit to operate from DHS.

Discharges of treated or untreated groundwater to surface water bodies or the storm drain system (such as during redevelopment of the production wells or other system maintenance activities) will require regulatory approval, typically in the form of National Pollutant Discharge Elimination System permits from the RWQCB.

3.2 Potential Sources and Nature of Release

The chemicals of interest (COIs) in the production wells are believed to have originated at the Facility. In accordance with various work plans submitted to DTSC, Whittaker is continuing subsurface characterization activities. These are expected to provide additional information regarding the sources of the COIs. The results and findings of ongoing many of the remedial investigation activities conducted onsite at the Facility by Whittaker have not yet been published, and have consequently not been incorporated into this IRAP.

3.3 Early Site Characterization Activities

At the direction of DTSC, the property owner, Remediation Financial, Inc., performed site characterization activities including collection and analysis of soil, groundwater and surface water (stormwater runoff) samples and installation of monitoring wells. These investigations identified several onsite potential source areas for COIs, including VOCs, perchlorate and explosives (Acton Mickelson Environmental Inc. 1995; Hargis 1999). These investigations also identified several onsite areas where soil and/or groundwater was impacted by COIs. Groundwater characterization, including installation of groundwater monitoring wells, was conducted in the northern portion of the Facility, OU5, during an investigation of chemical releases to groundwater resulting from former manufacturing activities at the Facility. Perchlorate, NDMA, TCE, PCE, HMX, and RDX were detected in monitoring wells within OU5 (Hargis 2000). Perchlorate and VOCs were also detected at elevated concentrations in reconnaissance groundwater samples collected at offsite locations approximately half a mile west of the Facility. Additional information on the analytical results and findings of the site investigation activities performed prior to 2002 is available in the source documents.

3.4 Eastern Santa Clara Sub-Basin Groundwater Study

In April 2002, the United States Army Corps of Engineers (USACE) and the Water Purveyors entered into a Feasibility Cost-Sharing Agreement to address groundwater contamination in the Eastern Santa Clara Basin. Site characterization activities were subsequently performed by USACE to characterize the perchlorate contamination within the alluvium and Saugus Formation. Although the Whittaker Facility and the perchlorate-contaminated aquifers have not been placed on the federal National Priorities List (NPL), the study was conducted following the guidelines of the CERCLA program to be consistent with the NCP.

On the basis of the site characterization activities performed by the USACE, conclusions regarding the hydrogeology and groundwater quality within OU7 have been developed and presented in the *Eastern Santa Clara Sub-Basin Groundwater Study, Santa Clarita, California – Conceptual Hydrogeology Technical Memorandum* dated January 2005 and prepared by CH2MHILL of Santa Ana, California on behalf of the USACE (CH2MHILL 2005). The scope of site characterization activities focused on evaluating the nature and extent of groundwater impacts within the eastern Santa Clara Valley, near the confluence of the Santa Clara River and the South Fork, approximately 2 miles northeast of Newhall, in Los Angeles County, California. This section of the IRAP summarizes the remedial investigation activities performed by USACE, as documented in USACE's technical memorandum (CH2MHILL 2005). The results of remedial activities performed by Whittaker at the Facility upgradient of the perchlorate-impacted Saugus Formation production wells are not yet available and have not been included in this IRAP.

As of October 2004, wells installed during Phase 1 were sampled three times and wells installed during Phase 2 were sampled twice (CH2MHILL 2005). Initial groundwater samples were analyzed for a comprehensive suite of analytes to establish "baseline" conditions, whereas subsequent monitoring targeted a more focused list of analytes. Samples were also collected from existing monitoring wells EM-1, EM-2, and EM-3 located at the Exxon-Mobil service station near Bouquet Junction west of the Site.

Analytical Results:
The initial analytical suite was developed through application of the Data Quality Objectives as presented in the project-specific Quality Assurance Project Plan (CH2MHILL 2005). Inputs to the analytical suite were partially based upon results of earlier site characterization and data evaluation activities, which were used to identify preliminary chemicals of potential concern (COPCs) including perchlorate, explosives (HMX and RDX), NDMA, VOCs, hexavalent chromium, and nitrate. Additionally, SVOCs, heavy metals, and depleted uranium were included as COPCs, pursuant to the Enforceable Agreement between DTSC and Whittaker (DTSC 2001).

Samples collected during alluvium reconnaissance groundwater sampling were analyzed for perchlorate and VOCs. Baseline samples collected from monitoring wells were analyzed for perchlorate, VOCs, nitroaromatics and nitroamines (explosive compounds including HMX and RDX), nitrosamines (including NDMA), other COIs (including 1,4-dioxane, SVOCs, chlorate, gross alpha and gross beta, cyanide, hexavalent chromium), metals (including major cations), major anions, alkalinity, total Kjeldahl nitrogen, nitrate, nitrite, ammonia, total dissolved solids, BOD, COD, and TOC (CH2MHILL 2005).

The location of reconnaissance groundwater sampling and monitoring well locations are shown on Figures 2-1 and 2-2 in Appendix A. Tables 3-8 through 3-11 of Appendix A summarize the analytical results for reconnaissance and monitoring well samples collected during the remedial investigation activities.

Although 28 different chemicals were detected in one or more groundwater samples, perchlorate, TCE, and PCE were detected with the greatest frequency in both onsite and offsite groundwater samples at concentrations exceeding the following regulatory action levels (CH2MHILL 2005):

Chemical	Notification Level	Source
Perchlorate	6 μg/l	California Department of Health Services Notification Level (DHS NL) and California Office of Environmental Health Hazard Assessment Public Health Goal (California PHG)
PCE	5 μg/l	California Environmental Protection Agency (Cal-EPA) Maximum Contaminant Level (MCL) and United States Environmental Protection Agency (USEPA) MCL
	0.08 μg/l	California PHG
TCE	5 μg/l	Cal-EPA and USEPA MCL
	0.06 μg/l	California PHG

The maximum concentrations of perchlorate, PCE, and TCE were detected in well MP-2_01 within the Facility (Note: "MP" indicates a Westbay® Multiport monitoring well, "-2" indicates the working model for the conceptual hydrogeology, hydraulic function of the Holser Fault, and to serve as a calibration data for the locally-scaled Regional Model.

Conceptual Hydrogeology:
Based on measurements of hydraulic head, observed responses to pumping from Saugus Formation production wells, geophysical and lithologic boring log interpretations, and March 2004 aquifer tests at NC-13 and V-205, 10 hydrostratigraphic units (HSUs) have been defined (CH2MHILL 2005), including:

- One Quaternary alluvium HSU
- Eight HSUs south of the San Gabriel Fault
- One Saugus HSU north of the San Gabriel Fault

Results of the aquifer testing described above suggests that there is a slight hydraulic connection between the Quaternary alluvium HSU and the upper Saugus HSUs, and pumping from the Saugus Formation may cause leakage across the Saugus HSUs (CH2MHILL 2005).

Hydraulic conductivity estimated for each of the HSUs using data collected during the aquifer testing varied by three orders of magnitude, which is consistent with the heterogeneities expected in the Saugus Formation. Hydraulic conductivity for the Saugus HSUs ranged from 0.1 to 38.6 ft/day, and were generally less than prior estimates (CH2MHILL 2005).

Based on groundwater level elevation data, groundwater flow in the alluvium is directed westward along the main reach of the Santa Clara River at a gradient of approximately 0.005 ft/ft, northward along the South Fork of the Santa Clara River at a gradient of approximately 0.0007 ft/ft, and westward downstream of the point where the two reaches of the Santa Clara River meet at a gradient of approximately 0.003 ft/ft (CH2MHILL 2005). Groundwater flow in the Saugus Formation is directed northwest in HSUs SI and SIII at gradients of 0.001 and 0.002 ft/ft, respectively, and west-southwest in HSU SVII at a gradient of 0.001 ft/ft. Vertical groundwater flow across the Saugus HSUs is generally downward at gradients ranging from 0.02 to 0.8 ft/ft, with the exception of HSUs SVIII and SVII, and varies seasonally with the operation of production wells (CH2MHILL 2005).

3.5 Groundwater Modeling

A three-dimensional numerical regional-scale groundwater flow model (Regional Model) of the valley based on the MicroFEM® finite-element software (Kemker and de Boer 2003) has been developed by the Water Purveyors for long-term water resource planning, a version of which has been locally scaled to predict groundwater flowpaths and capture zones for hydraulic control of contaminants. Details regarding the construction and calibration of the Regional Model are described and discussed in the *Regional Groundwater Flow Model for the Santa Clarita Valley: Model Development and Calibration* (CH2MHILL 2004a). A detailed analysis of the pumping plan is presented in the report titled *Analysis of Perchlorate Containment in Groundwater Near the Whittaker-Bermite Property, Santa Clarita, California* (CH2MHILL 2004b). Both of these reports on the Regional Model were approved by DTSC as they pertain to containment of perchlorate.

3.6 Possible Pathways of Contamination

Studies performed to date at the Facility suggest the following potential pathways for contamination of the affected production wells:

- Migration via surface water runoff
- Migration through the northern portion of the Quaternary alluvium from the Facility
- Migration through the vadose zone and into the Saugus Formation
- Migration along the San Gabriel fault zone

The first pathway involves surface water runoff from the Facility with COI migration into the alluvium west of the Facility. From within the alluvium, COIs would continue migrating downward into the groundwater of the Saugus Formation, and subsequently to the Saugus Formation production wells (Hargis 1999). The results of the USACE's remedial investigation activities appear to support this contaminant pathway. Perchlorate concentrations were detected in samples collected from the alluvium in the South Fork as far south as the mouth of Oakdale Canyon, which collects drainage from source areas within the Facility (CH2MHILL 2005). During 2003, Whittaker implemented short-term measures to minimize perchlorate migration via surface water drainage (CH2MHILL 2005).

The second contaminant pathway involves water containing COIs from the Facility that subsequently migrates downward in the alluvium on the north side of the Facility, and then continues vertically and horizontally with groundwater migration through the alluvium, ultimately traveling downward with migrating groundwater into the Saugus Formation and to the production wells (Hargis 1999). The results of the USACE's remedial investigation activities may also support this contaminant pathway. Concentrations of perchlorate, TCE, and PCE were detected in groundwater samples collected approximately 1 mile west of the Facility as far as Bouquet Junction, and perchlorate was detected as far as 2,500 feet southwest of Bouquet Junction (CH2MHILL 2005). These results suggest that the COIs have migrated within the alluvium west from the Facility along the southern edge of the Santa Clara River into the confluence of the Santa Clara River and the South Fork (CH2MHILL 2005).

The third contaminant pathways involves transport of water (i.e. surface water) vertically downward within the Facility boundaries, formation of perched zones that transport COIs laterally away from the Facility, and groundwater transport within the Saugus Formation resulting in COI migration to the production wells (Hargis 1999). The results of the USACE's remedial investigation activities also suggest COI migration through this contaminant pathway. Concentrations of perchlorate were detected in Well MP-2 within the Facility and at least 2 miles west of the Facility in Well MP-5 (CH2MHILL 2005). The analytical results of groundwater samples collected from these wells suggest that HSUs SI and SIII contain perchlorate at concentrations as high as 11.9 µg/l (CH2MHILL 2005). The laterally extensive distribution of perchlorate in the upper portion of the Saugus Formation may be the result of COI migration through the vadose zone of the Saugus Formation, a mechanism by which NC-11 may also have been impacted (CH2MHILL 2005).

The final contaminant pathway involves COI migration with groundwater traveling along the San Gabriel Fault. However, the fault, which bisects the Facility, appears to be a barrier to groundwater flow and contaminant transport in the Saugus Aquifer (CH2MHILL 2005).

Section 4: Summary of Human Health Risk Assessment

A human health risk assessment (HHRA) was performed to characterize the potential human health risks associated with domestic use of groundwater from the impacted production wells in the Saugus Formation, assuming that no reduction in concentration of contaminants through treatment or response actions occurs. The HHRA was conducted using methods and assumptions consistent with DTSC and USEPA guidance (DTSC 1994, USEPA 1989). The results of the HHRA were used in determining preliminary remediation goals (PRGs) for use in developing appropriate response actions.

4.1 Overview of Risk Assessment

The HHRA was performed by identifying chemicals of potential concern (COPCs), potentially exposed receptor populations and potentially complete exposure routes, and characterizing the potential health risk and hazards to potentially exposed human receptor populations. The HHRA was based on the most recent available groundwater data from the impacted Saugus Formation production wells and currently available toxicological data.

4.1.1 Chemicals of Concern

Groundwater data collected at the well-heads of the production wells are representative of the exposures that would occur from domestic use of the wells. Because the HHRA only evaluated risks associated with domestic use of the Saugus Formation production wells, only well-head data were used to identify COPCs requiring further evaluation. Available groundwater data from the most recent sampling events for the Saugus Formation production wells were used to identify the COPCs. Well-head samples were collected from Saugus 1, Saugus 2, and NC-11 in 2003. These samples were analyzed for multiple constituents, including perchlorate, VOCs, HMX, RDX, and NDMA.

Concentrations of chemicals detected in well-head samples were compared with drinking water standards to identify the COPCs. If the maximum detected concentration of a chemical was greater than the drinking water standard, that chemical was identified as a COPC requiring further evaluation. The comparison of detected concentrations in well-head samples with drinking water standards is presented in Table 3. Perchlorate was the only chemical identified as a COPC.

4.1.2 Exposure Assessment

The HHRA evaluated potential human health risks for individuals using water from within the pressure zones of the impacted production wells. Adult and child residents were identified as the potentially exposed populations based on consideration of current and future groundwater use scenarios.

Potential exposure pathways for domestic use of water are ingestion, inhalation, and dermal contact. Perchlorate is not volatile and droplets produced while showering are generally too large to be inhaled (OEHHA 2004), so inhalation was considered an incomplete exposure

4.2 Determination of Preliminary Remediation Goals

The results of the HHRA indicate that current concentrations of perchlorate in the Saugus Formation production wells could pose health hazards to adult and child residents if the impacted wells were used without treatment to supply water for domestic uses. The HHRA was based on available data for the production wells. Higher concentrations of perchlorate have been detected in upgradient groundwater monitoring wells, suggesting that the potential for health hazards could increase in the future.

Based on the results of the HHRA, a PRG for perchlorate needs to address the potential health hazards associated with domestic use of groundwater from the impacted production wells in the Saugus Formation. The OEHHA PHG of 6 µg/l was established for perchlorate in drinking water to be protective of sensitive subpopulations. Because the OEHHA PHG addresses the same populations and exposure pathways evaluated in the HHRA, the OEHHA PHG was selected as the PRG for perchlorate in groundwater from the impacted production wells.

Currently, there is no federal or state maximum contaminant level (MCL) for perchlorate. The notification level (NL) (which was referred to as an "action level" through 2004), used by the DHS for perchlorate is the same as the PHG.

The PRG clearly applies to residual concentrations of perchlorate in in-situ groundwater. However, achieving perchlorate concentrations equivalent to the PRG is not considered sufficient for groundwater to be provided for drinking water purposes. As a matter of practice and community acceptance, because the perchlorate-impacted production wells are considered "extremely impaired" with the framework of DHS Policy 97-005, therefore, it is anticipated that DHS will require that groundwater to be used for community supply purposes should be treated to achieve non-detectable concentrations of perchlorate.

- Restore the water supply capacity that was lost due to the presence of perchlorate in the Saugus Formation and to meet the timing and volume of expected demand

The schedule for implementation of the remedial strategy is a critical element of the RAOs. Timing is critical because the expected demand for this water supply, in part, is driven by expectations that the frequency of future drought years will follow historical patterns. Therefore, it can be expected that demand for this water supply will arise in the near future. In addition, there are anticipated demands for this water supply due to projected growth.

Although the Stadium Well and Well Q-2, alluvial aquifer production wells, have been impacted by perchlorate and removed from service, they are not part of this evaluation. The Stadium Well and Well Q-2 are located near the Santa Clara River generally downgradient from the northern portion of the Whittaker Facility (north of the San Gabriel Fault) where elevated levels of perchlorate have been detected in soil and groundwater samples. Operation of the Stadium Well will be evaluated following completion of source area characterization activities and implementation of source area remedial measures by Whittaker in the northern portion of the Facility. Additional subsurface characterization in the vicinity of the Stadium Well was identified as a priority subtask for OU7 in a letter from DTSC to Whittaker representatives dated 10 March 2003.

This IRAP is prepared by the Water Purveyors to evaluate alternatives for containment of the perchlorate plume in the Saugus Formation groundwater west of the Facility, and for restoration of the lost production capacity. As such this IRAP addresses a portion of OU7 groundwater. In accordance with its agreements with DTSC, Whittaker is currently performing additional groundwater investigations and will evaluate alternatives for remediation of other portions of OU7. Thus, this IRAP proposes a remedial measure that will be a component of the overall remedy to be selected in the future for OU7.

5.2 Applicable or Relevant and Appropriate Requirements

Although the area encompassing the capture zone of the four domestic water supply wells is not on the NPL, this IRAP has been developed to be consistent with the NCP. In evaluating remedial alternatives, the NCP requires consideration of ARARs, which it defines as follows (40 CFR 300.5):

> Applicable requirements are "...those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site."
>
> Relevant and appropriate requirements are "...those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that, while not 'applicable' to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site, address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well suited to the particular site."

- No Action
- Institutional Action
- Monitoring
- Alternate/Replacement Water Supply
- Monitored Natural Attenuation
- Containment
- Collection
- Treatment (In Situ and Ex Situ)
- Management/Reuse of Groundwater

The No Action response is necessary to establish a baseline for comparison with the other potential remedial actions. The No Action response assumes that no remedial action will be performed to reduce toxicity, mobility, or volume of perchlorate in groundwater. Therefore, the No Action response would include continued shutdown of the impacted Saugus Formation water production wells. However, the No Action response would still include ongoing groundwater monitoring to assess changes in chemical concentrations over time.

Institutional actions include legal, administrative, and procedural measures that will mitigate the risks of exposure to contaminated groundwater in the Saugus Formation by restricting access to the groundwater. Alternative/Replacement water supply actions involve the replacement of the impacted groundwater resources by unimpaired sources of water.

Containment involves implementation of a remedial action that significantly reduces the mobility of perchlorate in groundwater. Containment typically involves restricting the migration of the groundwater. Collection actions are methods for extracting groundwater from its present location in order to achieve hydraulic containment and perform treatment. Treatment involves implementation of a process that reduces chemical toxicity or transfers and concentrates chemicals in another medium, which may then require additional treatment. Management and/or reuse of groundwater actions are applied to treated groundwater following ex-situ treatment.

Response actions that are precluded by addressable media characteristics or identified as not applicable on the basis of increased understanding of addressable media conditions are eliminated from further consideration. This process will include identification of COPC characteristics that limit the effectiveness or applicability of certain technologies.

5.4 Initial Screening of Potential Technologies and Process Options

A range of potential technologies and more specific process options were identified for implementation of each GRA. Because perchlorate in groundwater is the only COPC, only technologies and processes considered effective in the remediation of perchlorate were considered. The following technology and process options were identified for the GRAs:

5.5 Evaluation of Technologies and Process Options

A further evaluation of the technologies and process options that were retained following the initial screening was conducted based on the screening criteria of effectiveness, and implementability, and the relative range of costs.

- Effectiveness addresses the ability of the technology to meet the RAOs for the COPC and quantity of impacted groundwater, mitigate potential impacts to human health and the environment during construction and implantation, and perform reliably with respect to the COPC (perchlorate) and conditions within the study area. Technologies were also rated in terms of their relative effectiveness compared to other technology options for the same GRA.

- Implementability is an evaluation of the site-specific technical and administrative feasibility factors involved in applying the technology. Factors affecting implementability include available resources, site hydrogeology and soil types, physical obstructions such as buildings, permitting requirements, and availability and proximity of treatment and disposal facilities.

- Overall costs were evaluated based on the components of both capital costs and long-term operation and maintenance (O&M) costs. Costs are estimated on the basis of engineering judgment, with each option evaluated as high, medium, or low relative to other options in the same category. Cost has a limited role in this phase of evaluation.

A summary of the evaluation of technologies and process options based on effectiveness, implementability, and cost is shown on Figure 5. The technologies and process options that were eliminated from further consideration are also indicated on Figure 5.

the lost domestic water supply capacity resulting from perchlorate impacts to groundwater within the Saugus Formation. Alternatives 2, 3, and 4 include resumed operation of Saugus 1 and 2, proper abandonment of VWC-157 and NC-11, modifications to the existing water distribution system, ex-situ treatment of the extracted groundwater at a site owned by CLWA, reuse of the treated groundwater, and development of additional water supply resources to mitigate production capacity lost due to the presence of perchlorate. The four remedial alternatives developed in the IRAP are described in more detail below and summarized on Figure 6.

6.1.1 Alternative 1: No Action

The No Action Alternative includes no remedial activities. The only technology implemented for Alternative 1, the No Action alternative, is groundwater monitoring. This alternative would include abandoning the four perchlorate-impacted Saugus Formation production wells, installation of two additional groundwater monitoring wells, and long-term monitoring of groundwater to monitor the movement of contaminants in groundwater. In accordance with the NCP, the No Action Alternative must be assessed for baseline comparison with other alternatives.

6.1.2 Alternative 2: Containment and Ion Exchange Treatment

Alternative 2 consists of hydraulic containment of perchlorate-impacted groundwater in the Saugus Formation by pumping from existing production wells Saugus 1 and 2, abandonment of Wells VWC-157 and NC-11, modifications to the existing domestic water supply distribution system, ex-situ treatment of groundwater by ion exchange using a resin that selectively removes perchlorate, and discharge of the treated groundwater to local domestic water supply service areas. The hydraulic containment pumping concept and proposed improvements to the existing water distribution system are described in Section 6.1.5. The ex-situ ion exchange treatment process is described in this section.

Under this alternative, an ion exchange treatment system would be located adjacent to the Rio Vista Intake Pump Station (RVIPS) on property that is owned by CLWA. The engineering components of the ion exchange system include pH adjustment, filtration to remove suspended solids, two ion exchange vessels with single-use perchlorate-selective resin operated in series, disinfection by chloramination, and a booster pump to discharge the treated groundwater into the 84-inch treated water pipeline from the Rio Vista Water Treatment Plant (RVWTP). The spent resin would require periodic removal, replacement, and offsite incineration. During incineration the perchlorate ion undergoes complete thermal destruction, eliminating the possibility of generating a new waste stream.

Operation and maintenance elements for Alternative 2 include sentinel groundwater monitoring, electrical power for operation of the well pumps, on-going monitoring of influent and treated water, resin replacement, disinfection chemicals, and management of spent resin. The generalized conceptual process flow diagram is shown on Figure 7.

On behalf of CLWA, Carollo Engineers (Carollo) conducted a bench-scale analysis of ion exchange treatment to evaluate the effectiveness of ion exchange for treating water from the Saugus Formation. Three single-pass perchlorate-selective ion exchange resins were evaluated at the bench-scale (Carollo 2004). Perchlorate breakthrough (identified as perchlorate

On behalf of CLWA, Carollo also performed a pilot scale study of biological treatment for perchlorate-impacted groundwater. The study included testing of both the FBR and FXB biological treatment systems (Carollo 2004). Perchlorate removal to concentrations less than the laboratory detection limit was consistently achieved in the FXB system using only organisms indigenous to the Saugus Formation. Effluent from the FXB system was biologically stable and contained no fecal coliforms. Challenge tests showed that the FXB system was robust with respect to backwashing episodes, changes in feed water quality, system shut-downs, and electron donor addition failures. Analysis of disinfection bypropducts (DBP) for the FXB system resulted in trihalomethane (THM) and haloacetic acid (HAA) concentrations lower than the MCL established under the EPA Stage 2 Disinfection Byproduct Rule (Carollo 2004).

During the pilot test, the FBR system did not achieve perchlorate removal to concentrations below the detection limit over a period greater than eight days. Testing did demonstrate that biological removal of perchlorate can be achieved using indigenous microorganisms in a FBR system, a result that had not been previously demonstrated for the FBR system (Carollo 2004).

The biological reduction process is currently in use at other sites where groundwater is impacted with perchlorate. DHS requires case specific approval of treatment technologies for perchlorate removal for drinking water. DHS has given a conditional acceptance of biological treatment using an FBR to remove perchlorate from drinking water at another site; however, DHS has not issued a permit to any facility that uses biological treatment for domestic water supply.

6.1.4 Alternative 4: Containment and Membrane Filtration Treatment

Alternative 4 consists of hydraulic containment of perchlorate-impacted groundwater in the Saugus Formation by pumping from existing production wells Saugus 1 and 2, abandonment of Wells VWC-157 and NC-11, modifications to the existing domestic water supply distribution system, ex-situ treatment of groundwater by membrane filtration, disinfection by chloramination and discharge of the treated groundwater to local domestic water supply service areas. The hydraulic containment pumping concept and proposed improvements to the existing water distribution system are described in Section 6.1.5. The ex-situ membrane filtration treatment process is described in this section.

Membrane filtration technology makes use of semi-permeable membranes to remove undesired dissolved ions in water. There are three main types of membranes, which include high-pressure reverse osmosis (RO) membranes, nanofiltration (NF) membranes, and low-pressure RO membranes. RO membranes are expected to achieve removal of perchlorate ions, however, there is currently little available performance data on perchlorate removal using membrane technologies. The American Water Works Association Research Foundation (AwwaRF) is supporting an ongoing research project to investigate the feasibility of membrane filtration technology for the removal of perchlorate from water sources of different quality (DTSC 2004).

A bench scale study of perchlorate rejection by high-pressure membranes, and brine stream treatment by chemical and biological processes, was conducted by the University of Colorado using synthetic water based upon Saugus Formation groundwater samples provided by CLWA. Two types of RO membranes and two types of NF membranes have been tested. Only one of the four membrane types was shown to satisfy the PRG of 6 µg/l of perchlorate. Concentrated contaminated groundwater, shown as a thick broken line on Figure 10. Containment water from Wells Saugus 1 and 2 would discharge to the converted Newhall Lateral through an existing 14-inch SCWD pipeline that crosses the South Fork. A new 10-inch pipeline (thick unbroken line on Figure 10) would be installed to connect Wells Saugus 1 and 2 to the existing 14-inch SCWD pipeline. Contaminated groundwater will cross the Santa Clara River through a new 16-inch pipeline (thick unbroken line on Figure 10), which would deliver contaminated water to the RVIPS on Bouquet Canyon Road where the water would be treated to remove perchlorate.

A groundwater treatment system rated for a capacity of at least 2,400 gpm would be constructed immediately west of the existing RVIPS on land owned by CLWA that is secure and has existing support facilities. Construction will include installation of a connection to allow pumping of treated groundwater into either the existing 84-inch treated water distribution pipeline or the 102-inch raw water supply pipeline that are located adjacent to the RVIPS. Containment water delivered to the treatment system would be treated by CLWA according to the requirements of DHS. Although the treatment system would not be staffed on a continuous basis, it would be monitored remotely through a SCADA system from the RVWTP, which is staffed 24 hours per day. CLWA operators would visit the treatment system as required. Either treated surface water from the RVWTP or raw surface water entering the RVWTP would be used as a source of blending water to blend with and dilute the treated groundwater. The RVWTP currently has a capacity of 20,800 gpm with an average flowrate of 10,400 gpm. The specific pipeline selected to provide blending is dependent on the alternative chosen to treat the groundwater. Tie-in locations were discussed in more detail in the sections describing the three treatment alternatives.

Existing Wells VWC-157 and NC-11 will be properly abandoned. A new cluster monitoring well would be installed near Well Saugus 1, as well as additional wells necessary to provide a sentinel and performance monitoring network. The new monitoring wells would address the requirement of DHS Policy 97-005 and would provide groundwater monitoring in both the Alluvium and Saugus Formation. The upgradient monitoring wells required by DHS Policy 97-005 would be monitored by CLWA at a frequency established by DHS and DTSC. Monitoring events would be coordinated with the monitoring activities conducted at the Facility.

6.1.6 Replacement of Lost Production Capacity

The Water Purveyors have experienced lost water production capacity as a result of perchlorate contamination in the production Wells Saugus 1, Saugus 2, VWC-157, and NC-11. As proposed in this IRAP, future groundwater production from the existing impacted wells will be less than the production capacity prior to contamination of the wells. Pumping rates will be limited to less than the pre-contamination pumping rates in order to balance the need for containment of the perchlorate plume in groundwater with the need to design and operate a cost-effective perchlorate treatment system.

As a water supply issue, replacement of the remaining lost water production capacity is outside the scope of this IRAP, but it is nevertheless a significant component of pending agreements between the Water Purveyors and Whittaker. For the purpose of completeness, this section provides a brief summary of the issue and its potential resolution to provide the reader with a sense of the overall plan for restoration of lost production capacity. Costs for water supply threaten its availability as a firming supply. Moreover, operating the Saugus Formation wells continually at their hydraulic capacity is inconsistent with the Water Purveyors' Urban Water Management Plan. Constructing replacement wells that will not require perchlorate treatment and that would be operated on an as-needed basis, is considered a more cost-effective approach for providing potable water during conditions of reduced supplies from other water supply sources.

Alternatives 2, 3 and 4 contemplate construction of a perchlorate treatment system immediately west of the RVIPS. Treatment of groundwater at the RVIPS offers the advantage of the land already owned by CLWA, thus reducing land acquisition costs potentially associated with construction of a perchlorate treatment system at another location. Proximity of the proposed perchlorate treatment system to the existing RVIPS is expected to provide operational synergies. Moreover, an existing 84-inch diameter pipeline conveying treated water is located adjacent to the RVIPS, and injecting the treated groundwater into this 84-inch pipeline will provide considerable dilution of the treated groundwater and thus redundancy regarding potential agency or community concerns regarding removal of perchlorate and protection of human health. Alternatively, for Alternative 3 involving biological treatment to remove perchlorate, the groundwater could be pumped from the perchlorate treatment system into the existing 102-inch diameter raw water pipeline running from the RVIPS to the RVWTP.

Implementation of Alternatives 2, 3 or 4 would also include ongoing monitoring of groundwater upgradient of Wells Saugus 1 and Saugus 2 to evaluate potential changes in chemical concentrations in groundwater approaching the production wells. Sentinel wells would be installed and monitored for this purpose. Chemicals other than perchlorate have been detected in groundwater samples collected from other wells, and the purpose of the sentinel monitoring program would be to provide sufficient early warning regarding the approach of chemicals in groundwater that could potentially require modification of the treatment system. If necessary, additional unit processes could be added to the treatment system to provide treatment for the newly-arriving chemicals in groundwater.

In accordance with applicable DHS requirements, Alternatives 2, 3 and 4 would also include monitoring of the treatment process to confirm its effectiveness and provide process control.

6.2 Detailed Analysis of Alternatives

To provide a basis for the selection of a preferred alternative, the four remedial alternatives developed in the previous section have been analyzed to evaluate the extent to which they meet the RAOs. The remedial alternatives were evaluated against the criteria established in the NCP.

6.2.1 Statutory Requirements

The detailed analysis addresses the statutory requirements for the remedial action. The statutory requirements state that the remedial actions should:

- Be protective of human health and the environment
- Attain ARARs or provide grounds for invoking a waiver
- Be cost-effective

- Implementability
- Cost

Risk is an important factor in the analysis of effectiveness and permanence. The analysis evaluates the residual risk after the response objectives have been met. The evaluation also considers the potential impacts on human health and the environment if the remedy fails. The evaluation is performed in a narrative fashion for each of the five balancing criteria.

The last two criteria are considered *modifying* criteria and do not include risk information:

- State acceptance
- Community acceptance

These criteria are evaluated after public comments are received on the proposed IRAP.

These evaluation criteria are used to conduct a detailed analysis and to select an appropriate remedial action. Application of these criteria is address in the USEPA Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA (USEPA 1988). A detailed evaluation of the four remedial alternatives is presented in the following sections and Tables 7 through 10 summarize the assessment of each alternative with respect to the nine evaluation criteria. The assessment incorporates the cost analysis discussed in Section 6.2.7 and summarized in Table 11.

6.2.3 Alternative 1: No-Action Alternative

Overall Protection of Human Health and the Environment:
While discontinued operation of the impacted production wells is a stop gap measure to protect the community from ingestion of perchlorate, Alternative 1 provides no overall protection for human health and the environment because it does not remove perchlorate from the drinking water resource. Alternative 1 does not address existing and continued further impacts to groundwater, nor does Alternative 1 provide measures to contain the migration of contaminated groundwater in the Saugus Formation. Without containment measures in place, downgradient wells that are currently not impacted by the perchlorate are more likely to be impacted in the future.

Compliance with ARARs:
Alternative 1 will not achieve compliance with ARARs because it does not reduce perchlorate concentrations to water quality objectives within a reasonable period of time. Prior to the identification of perchlorate impacts in the Saugus Formation, this groundwater resource was used for drinking water supply. Alternative 1 is inconsistent with State Water Resources Control Board Resolution 88-63 (Sources of Drinking Water Policy), Resolution 68-16 (Non-Degradation Policy) and the Water Quality Control Plan for the Los Angeles Region. Resolution 88-63 designates all groundwater within the state as a potential source of drinking water except where concentrations of total dissolved solids exceed 3,000 parts per million (ppm) or the yield from a single well is less than 200 gallons per day. The Non-Degradation Policy addresses preservation of water quality to preserve beneficial uses. The Water Quality Control Plan for the Los Angeles Region, authorized under Division 7 of the California Water Code, designates municipal water supply as a beneficial use of the Saugus Formation groundwater.

6.2.4 Alternative 2: Containment and Ex-Situ Treatment – Ion Exchange

Overall Protection of Human Health and the Environment:
Currently, institutional controls (discontinued operation of the production wells impacted by perchlorate) ensure protection of human health only to the extent that the affected groundwater is not used for water supply. The groundwater pumping component of Alternative 2 reduces existing and continued further impacts to a public water supply (Saugus Formation groundwater).

Under Alternative 2, ex-situ treatment of groundwater utilizing a DHS-approved technology, as confirmed by ongoing monitoring of the treatment system, will provide adequate protection to the water system users. Moreover, groundwater treated by ion exchange and chloramination will be pumped into the 84-inch treated water distribution line and blended with imported water that has been treated at the RVWTP. Blending of the treated groundwater with imported CLWA water provides increased reliability and protection of human health.

Compliance with ARARs:
Based on current understanding, it is expected that compliance with identified chemical-specific, location-specific, and action-specific ARARs can be achieved with Alternative 2. The state has promulgated a PHG of 6 µg/l of perchlorate in drinking water. The perchlorate PHG is considered a chemical-specific ARAR for evaluation of alternatives for water supply restoration.

During design and construction of the groundwater piping and treatment systems, ARARs can be satisfied. The proposed treatment of groundwater will satisfy the requirements of DHS Policy 97-005.

During operation, it is anticipated that the ion exchange treatment process will reduce perchlorate to concentrations less than 6 µg/l. However, compliance with chemical-specific ARARs can be evaluated through groundwater monitoring and monitoring of the groundwater treatment process.

Long-Term Effectiveness and Permanence:
Ion exchange technology is proven to be effective over the long term with proper operation. This alternative will mitigate the loss of the water supply associated with the portion of the Saugus Formation currently impacted by perchlorate and reduce the potential for additional water supply loss. Alternative 2 provides for partial recovery of water production capacity compared with capacity available prior to the shutdown of wells impacted by perchlorate. The groundwater pumping component of Alternative 2 is expected to reduce the risk of perchlorate migration in the Saugus Formation and potential loss of other water production wells. Based upon the current understanding of the nature and extent of groundwater impacts, Alternative 2 provides the flexibility to achieve hydraulic containment of the groundwater as well as providing a system that can be managed to respond to future information regarding contaminant mobility or to optimize the system.

Reduction of Toxicity, Mobility, and Volume Through Treatment:
Perchlorate mass will be removed from the subsurface by groundwater pumping, and from the extracted groundwater by the ion exchange treatment process. Alternative 2 satisfies the

Community Acceptance:
Community acceptance is unknown at this time. However, based on the Water Purveyors' sense of the public water system user concerns, the community would be likely to accept ion exchange treatment to restore the water supply capacity. As noted above, blending of the treated groundwater with treated surface water is expected to alleviate potential concerns of the water consumers.

6.2.5 Alternative 3: Containment and Ex-Situ Treatment – Bioreactor

Overall Protection of Human Health and the Environment:
Currently, institutional controls (discontinued operation of the production wells impacted by perchlorate) ensure protection of human health only to the extent that the impacted groundwater is not used for water supply. The groundwater pumping component of Alternative 3 reduces the existing and future impacts to a public water supply (Saugus Formation groundwater).

Ex-situ biological treatment is recognized as a means of removing perchlorate from water. In addition, the treatment process monitoring component will provide adequate protection to the water system users. Moreover, groundwater treated by biological treatment will be pumped into the 102-inch CLWA raw water pipeline for further treatment (blending, filtration and disinfection) at the RVWTP. Blending of the treated groundwater with imported CLWA water provides increased reliability and protection of human health. Biological treatment may provide the added benefit of some removal of VOCs such as TCE and PCE through volatilization and microbial consumption.

Compliance with ARARs:
Based on the current understanding, it is anticipated that compliance with identified chemical-specific, location-specific, and action-specific ARARs can be achieved with Alternative 3. The state OEHHA has promulgated a PHG of 6 μg/l for perchlorate in drinking water. The perchlorate PHG is considered a chemical-specific ARAR for evaluation of alternatives for water supply restoration.

During design and construction of the groundwater piping and treatment components, ARARs will be considered and incorporated. The proposed treatment of groundwater will satisfy the requirements of DHS Policy 97-005.

During operation, it is anticipated that the biological treatment process will reduce perchlorate to concentrations less than 6 μg/l in the extracted groundwater, however, compliance with chemical-specific ARARs will be evaluated through monitoring of the groundwater treatment process. The effectiveness of the groundwater pumping in achieving ARARs will be evaluated through groundwater monitoring.

Long-Term Effectiveness and Permanence:
Both biological treatment systems are shown to remove perchlorate. A pilot study on biological treatment was conducted on behalf of CLWA to confirm whether biological treatment would be able to achieve the PHG established for perchlorate. Consistent removal of perchlorate to concentrations less than the detection limit was achieved in the FXB system, however the FBR system did not achieve consistent perchlorate removal to concentrations less than the detection limit (Carollo 2004). However, there is an FBR perchlorate removal system that has been

Cost:
Alternative 3 has a high estimated 30-year present value ($45.13 million) relative to Alternative 1. Alternative 3 has a lower present value than Alternative 2 and a much lower present value than Alternative 4.

State Acceptance:
DHS has provided conditional site-specific acceptance for an FBR system at another location in California. Review and formal approval for any proposed design using this technology for specific water systems will be handled on a case-by-case basis. Because the use of biological treatment in drinking water applications is relatively uncommon, state acceptance may be more difficult than for Alternative 2.

Community Acceptance:
Community acceptance is unknown at this time. However, based on the Water Purveyors' sense of the public water system user needs, the community may be resistant to the use of biological treatment for drinking water.

6.2.6 Alternative 4: Containment and Ex-Situ Treatment – Membrane Filtration

Overall Protection of Human Health and the Environment:
Currently, institutional controls (discontinued operation of the production wells impacted by perchlorate) ensure protection of human health only to the extent that the impacted groundwater is not used for domestic/municipal water supply. Existing and continued further impacts to groundwater would be reduced through the groundwater pumping component of Alternative 4.

Under Alternative 4, ex-situ treatment of groundwater, as confirmed by ongoing monitoring of the treatment process, will provide protection to consumers. Moreover, groundwater treated by membrane filtration and chloramination will be pumped into the 84-inch treated water distribution pipeline and blended with imported water that has been treated at the RVWTP. Blending of the treated groundwater with imported CLWA water provides increased reliability and protection of human health.

Compliance with ARARs:
Based on the current understanding, it is anticipated that compliance with identified chemical-specific, location-specific, and action-specific ARARs can be achieved with Alternative 4. The state OEHHA has promulgated a PHG of 6 μg/l for perchlorate in drinking water. The perchlorate PHG is considered a chemical-specific ARAR for evaluation of alternatives for water supply restoration.

During design and construction of the groundwater piping and treatment components, ARARs will be considered and incorporated. The proposed treatment of groundwater will satisfy the requirements of DHS Policy 97-005.

During operation, it is anticipated that the membrane filtration process will reduce perchlorate concentrations in the extracted groundwater to less than 6 μg/l, however, compliance with chemical-specific ARARs will be evaluated through monitoring of the groundwater treatment process.

concentrations of perchlorate and other dissolved solids, and must be appropriately treated and disposed.

Short-Term Effectiveness:
Alternative 4 will be effective, subject to the limitations previously discussed, in achieving the water supply RAOs. The effectiveness of hydraulic containment of Saugus Formation groundwater can be evaluated through groundwater monitoring during operation.

Additional pilot testing, and possibly full-scale testing, would probably be required to demonstrate the effectiveness of membrane filtration in removing perchlorate. It is anticipated that there will be some disruptions in local vehicle traffic as new water conveyance pipelines are constructed within City streets.

Implementability:
Alternative 4 can be implemented in two to four years. Construction and operation of the pumping and treatment components are well understood. The treatment process can be monitored to ensure that the system is effective and reliable. Regulatory agency approvals are expected to be obtainable. Coordination with other agencies is possible where necessary. The required equipment is available.

Cost:
Alternative 4 has the highest estimated present value ($73.08 million) relative to the other alternatives. Due to various unknowns, the estimated operation and maintenance costs, and estimated present value, do not include costs for disposal of reject water (brine) resulting from treatment by membrane filtration. These additional ongoing operational costs could be substantial.

State Acceptance:
State acceptance is unknown at this time. This criterion can be further addressed and evaluated when comments are received on this IRAP.

To date, DHS has not permitted membrane filtration systems for perchlorate removal. It is anticipated that additional pilot study and further evaluation of brine management would be necessary to obtain approval from DHS. Because the use of membrane filtration for perchlorate removal is relatively uncommon, state acceptance may be more difficult than for Alternative 2.

Community Acceptance:
Community acceptance is unknown at this time. However, based on the Water Purveyors' sense of the public water system user needs, the community would be likely to accept membrane filtration treatment to restore the water supply capacity.

6.2.7 Cost Analysis

The cost analysis for each alternative and its component technologies includes consideration of site-specific factors identified from available information and determined during development of the alternative. The cost estimates are planning level costs and are developed to plus 50% or minus 30% accuracy. The sources for these cost estimates include vendors, estimates for

- Auxiliary materials and energy – chemicals, electricity, water, sewer, fuel
- Purchased services – sampling, analytical laboratory
- Periodic site reviews – may be required by DTSC as part of the overall remedial strategy for OU7 at least every five years as long as perchlorate remains present in groundwater

Operation and maintenance costs are summarized for each alternative in Appendix C.

Present-Value Analysis:
Present value analysis is used to evaluate expenditures that occur over different time periods by discounting all future costs to the present. Due to the uncertainties associated with the distribution, quantity, movement, nature and extent of the perchlorate, there are likewise uncertainties associated with the required performance periods of the various alternatives. Therefore, the period of performance is limited to 30 years for the purpose of comparative analysis. Costs in each planning year are estimated in constant dollars, representing the general purchasing power at the time of construction. Consistent with CERCLA guidance, a real discount rate of 3.5 percent, with a base year of 2004, is assumed in the present value analysis, as indicated for a 30-year maturity in Circular A94 (OMB 2005). Data developed in the present value analyses are summarized for each alternative in Appendix C. The estimated 30-year present-value for each alternative is as follows:

- Alternative 1 – $1.71 million
- Alternative 2 – $51.84 million
- Alternative 3 – $45.13 million
- Alternative 4 – $73.08 million

6.2.8 Comparative Analysis

The technology assessments and risk management judgments from the individual criteria assessment are used to rank the alternatives based on the comparative advantages and disadvantages of each alternative. The relative performances of the alternatives are compared for each evaluation criterion to evaluate the strengths and weaknesses of the alternatives and identify substantive differences among alternatives.

The threshold criteria of overall protectiveness and compliance with ARARs must be met before a remedy can be selected. Alternative 1 does not meet criteria for overall protectiveness because existing and continued further chemical impacts to groundwater are not addressed. Alternative 1 does not comply with ARARs because it is inconsistent with SWRCB Resolution 88-63 (Sources of Drinking Water Policy), SWRCB Resolution 68-16 (Non-Degradation Policy), the Porter Cologne Water Quality Act, and the Water Quality Control Plan for the Los Angeles Region. Alternatives 2, 3, and 4 meet the threshold criteria. Comparison of the balancing criteria are discussed below and are summarized in Table 12.

Long-Term Effectiveness and Permanence:
Alternative 1 ranks lowest with regard to long-term effectiveness and permanence. The controls provided in Alternative 1 are not adequate to achieve the RAOs for the reasonably foreseeable future. The residual risk that would be present as a result of implementing Alternative 1 would preclude utilization of the affected groundwater for water supply purposes. Protection is

uncertainties related to limited performance data and agency acceptance for a full-scale perchlorate removal system, Alternative 4 may rank relatively lower than Alternative 2.

Implementability:
Alternative 1 ranks high in the implementability criteria because it can be implemented within 1 year with minimal construction impacts or regulatory interaction. In addition, Alternative 1 provides the flexibility of undertaking remedial actions in the future with respect to both the RAOs set forth in this IRAP and for RAOs that may be developed. However, deference of active remedial measures with respect to the RAOs in this IRAP will result in continued unavailability of a portion of the community water supply.

Alternative 2 ranks high in this criterion and can be implemented in 1 to 2 years. Alternatives 3 and 4 rank slightly lower than Alternative 2 and can be implemented in 2 to 4 years. Construction and operation of the system is well understood for both Alternative 2 and 4. The Alternative 2 and Alternative 4 technologies represent controlled physiochemical processes and can be monitored to ensure that the system is effective. Alternative 3 is not known to provide the same level of reliability and may incur increased downtimes relative to the other alternatives. Agency approvals are believed to be obtainable for all of the alternatives and coordination with other agencies is possible where necessary. The ion exchange process in Alternative 2 is already a DHS-approved technology for drinking water applications giving it an advantage in this category over the other alternatives.

Cost:
Alternative 1 ranks high in the cost criteria. However, Alternative 1 ranks the lowest of the alternatives with regard to three other balancing criteria. Estimated costs for Alternatives 2 and 3 are similar, although the cost estimates in this IRAP are developed to plus 50 percent or minus 30 percent accuracy and the differences in magnitude between Alternative 2 and Alternative 3 could be significantly less or greater. The estimated cost for Alternative 4 is the highest.

State Acceptance:
In general, state acceptance is unknown at this time for all of the alternatives. This criterion can be further addressed and evaluated when comments are received on this IRAP.

However, state acceptance of Alternative 1 is considered unlikely because it provides no protection for groundwater resources known to be otherwise suitable for water supply. State acceptance of Alternatives 3 and 4 is somewhat uncertain due to the relative lack of full-scale treatment systems demonstrating the effectiveness of the treatment process in reducing perchlorate concentrations. Largely due to the successful and effective operation of several similar ion exchange treatment systems State acceptance of Alternative 2 is considered most likely.

California DHS Policy Memo 97-005, which applies to water sources determined to be “extremely impaired”, requires performance of several evaluations prior to returning a chemically-impacted production well to use for community water supply purposes. These evaluations include: source water characterization, alternatives evaluation, risk assessment, process demonstration, and agency and public acceptance, submittal of a permit application and conducting a public hearing (DHS 1997). Implementation of Alternatives 2, 3 or 4, which involve restoring Wells Saugus 1 and Saugus 2 to production, will trigger the requirement for

Section 7: Selection of the Preferred Remedial Alternative

7.1 Recommended Remedial Alternative

The recommended remedial alternative is selected in accordance with the requirements of the NCP and CERCLA, as amended by SARA. Additionally, the recommended remedial alternative is based on the technology and process option screening and remedial alternative development and evaluation processes discussed in Sections 5 and 6. Based on the current understanding of the aquifer characteristics and the nature and extent of the perchlorate in groundwater, the detailed evaluation process described in Section 6 identifies Alternative 2 as the preferred remedial alternative. Alternative 2 involves ex-situ treatment of groundwater by ion exchange. The ion exchange system is the only system currently approved by DHS for removal of perchlorate from drinking water. A more detailed description of Alternative 2 is provided in Section 6, and a conceptual plan for Alternative 2 is shown on Figure 7.

Alternative 2, hydraulic containment with groundwater collection and ex-situ treatment with ion exchange, maintains the best estimated performance relative to the balancing evaluation criteria. Alternative 2 ranks high in long-term effectiveness and permanence and in reduction of mobility, toxicity, or volume of perchlorate in contaminated groundwater through the use of treatment and ranks high in short-term effectiveness. Chemical mass is removed on a "demand" basis through the ion exchange treatment process and the ion exchange technology is proven to be effective over the long term with proper operation. Alternative 2 can be implemented in 1 to 2 years and will be effective in meeting the RAOs immediately upon implementation. The ion exchange process is already a DHS-approved technology for drinking water applications. Although Alternative 2 has high estimated present value, it is similar in magnitude of cost to Alternative 3 and less than Alternative 4. In addition, Alternative 2 meets both of the threshold evaluation criteria and will likely meet the modifying criteria.

Based on the detailed analysis present in Section 6, Alternative 2 best satisfies the RAOs described in Section 5 of this IRAP. Alternative 2 affords a flexible design that can be tailored to meet the PRG (or FRG) once established. Additionally, Alternative 2 satisfies the statutory requirements because it is protective of human health and the environment, attains ARARs, is cost-effective; it utilizes a permanent solution and alternative treatment technologies to the maximum extent practicable; and it satisfies the preference for treatment that reduces toxicity, mobility, or volume as a principal element. A confirmation sampling program will be implemented to obtain data to evaluate the effectiveness of the groundwater extraction component and to confirm the effectiveness of the perchlorate treatment component. The proposed sampling program is summarized in Appendix D.

The schedule for implementation of the remedial strategy is a critical element of the RAOs. Timing is critical because the expected demand for this water supply, in part, is driven by expectations that the frequency of future drought years will follow historical patterns. Therefore, it is expected that demand for this water supply will arise in the near future. Alternative 2 provides the best certainty with regard to this key time element. This preferred alternative will partially mitigate the loss of the water supply associated with the portion of the Saugus Formation currently impacted by perchlorate and reduce the potential for additional future water supply loss. Alternative 2 provides a partial replacement of the contaminated water supply fact sheet summarizing the IRAP was prepared and distributed to parties on the DTSC and CLWA mailing lists in August 2005. A public notice was placed in the local newspaper in August 2005.

A Mitigated Negative Declaration was prepared by CLWA and filed in accordance with applicable requirements of the Public Resources Code. A copy of the document is included in Appendix E.

A public meeting was hosted by DTSC in the Santa Clarita City Hall on 7 September 2005 and a public hearing on the CEQA determination was held by CLWA on 14 September 2005. Copies of these meeting transcripts are included in Appendix F.

Comments were received from the public and written responses to these comments were prepared by DTSC in the form of a Responsiveness Summary. The Responsiveness Summary is included in Appendix G of this IRAP.

Appendix H provides a list of documents which were relied upon in preparing this IRAP and in developing the recommended remedial alternative.

	Compliance with applicable or relevant and appropriate requirements (ARARs)	Does not meet criteria	Meets criteria	Meets criteria	Meets criteria
Balancing Criteria	Long-term effectiveness and permanence	4	1	1	3
	Reduction of mobility, toxicity, or volume through treatment	4	1	1	1
	Short-term effectiveness	4	1	2	2
	Implementability	1	2	4	2
	Cost	1	3	2	4
	Sum of Rankings:	**14**	**8**	**10**	**12**
Modifying Criteria	State acceptance	Unknown, but likely unfavorable	Unknown, but likely favorable	Unknown, but potentially unfavorable	Unknown, but likely favorable
	Community acceptance	Unknown, but likely unfavorable	Unknown, but likely favorable	Unknown, but likely unfavorable	Unknown, but likely favorable

(a) Alternatives were ranked, with "1" considered the best and "4" the worst. Ties were assigned the lowest common value.

Table 11: Comparison of Total Cost of Remedial Alternatives

Description	Alternative 1	Alternative 2	Alternative 3	Alternative 4
	No Action	Containment and Ex-Situ Treatment with Ion Exchange	Containment and Ex-Situ Treatment with Bioreactor	Containment and Ex-Situ Treatment with Membrane Filtration
Total Project Duration (Years)	30	30	30	30
Undiscounted Capital Cost	$0.97	$7.15	$15.09	$19.70
Undiscounted Annual O&M Cost Odd Year/Even Year	$0.03/$0.04	$2.42/$2.44	$1.63/$1.64	$2.90/$2.91
Total Present Value of Alternative (Real Discount Rate of 3.5%)	$1.71	$51.84	$45.13	$73.08

(a) Costs are in millions of dollars.
(b) Base year for opinion of costs is 2004.
(c) Quantities and costs are not based on an engineered design, but rather reflect a concept-level assessment of system components and are based on experience at the Site and with similar projects. This opinion of costs is estimated to range from -30% to +50% accuracy.

Table 10: Evaluation of Alternative 4

Alternative: Ex-Situ Treatment with Membrane Filtration

Description: Utilize existing water distribution infrastructure (with some modifications), construct membrane filtration treatment facility, install two monitoring wells, and conduct long-term monitoring.

	Evaluation Criteria	Comments
Threshold Criteria	Overall protectiveness	Membrane filtration treatment technology as well as the monitoring components will provide adequate protection to the water system users. Existing and continued further impacts to groundwater are reduced with Alternative 4.
	Compliance with applicable or relevant and appropriate requirements (ARARs)	Compliance with identified chemical-specific, location-specific and action-specific ARARs can be achieved with Alternative 4. California Department of Health Services (DHS) Policy Memo 97-005 may be applicable.
Balancing Criteria	Long-term effectiveness and permanence	Treatment technology is likely to be effective over the long term with proper operation. This alternative will partially remedy and mitigate the loss of the water supply. Reduces the potential for additional future water supply loss. Residual risk will be reduced. Treated groundwater will be pumped into an existing 84-inch water distribution pipeline. Rio Vista Water Treatment Plant capacity for treatment of imported water not affected. Treatment and disposal of the brine is required.
	Reduction of mobility, toxicity, or volume through treatment	Chemical mass is removed on a "demand" basis through the treatment process. Unknown quantities of perchlorate are expected to remain in the Saugus Formation as well as in upgradient impacted areas. Contaminant mobility reduced through hydraulic containment.
	Short-term effectiveness	Alternative 4 can be implemented in a relative short time (2-4 years) and will be effective, subject to the limits previously discussed, against the remedial action objectives immediately upon implementation. Membrane filtration is a DHS-approved technology for drinking water applications for other chemicals.
	Implementability	Alternative 4 can be implemented in 2-4 years. Construction and operation of the system is well understood. The process is reliable and can be monitored to ensure that the system is effective. Agency approvals are believed to be obtainable. Required equipment is available.
	Cost	Alternative 4 has the highest estimated present value ($73.08 M) relative to the other alternatives.
Modifying Criteria	State acceptance	State acceptance is unknown at this time. This criterion can be further addressed and evaluated when comments are received on this Interim Remedial Action Plan (IRAP).
	Community acceptance	Community acceptance is unknown at this time. The community is likely to accept membrane filtration treatment to restore the water supply capacity. This criterion can be further addressed and evaluated when comments are received on this IRAP.

Table 9: Evaluation of Alternative 3

Alternative: Ex-Situ Treatment with Cometabolic Bioreactor

Description: Utilize existing water distribution infrastructure (with some modifications), construct cometabolic biological reactor treatment facility, install two monitoring wells, and conduct long-term monitoring.

	Evaluation Criteria	Comments
Threshold Criteria	Overall protectiveness	Biological treatment technology using a fixed bed biological reactor (FXB) system has been shown to consistently remove perchlorate to concentrations below the analytical detection limit. Thus, biological treatment as well as the monitoring components, will provide adequate protection to the water system users. Existing and continued further impacts to groundwater are reduced with Alternative 3 through hydraulic containment and mass removal. May achieve some removal of other contaminants of interest, such as TCE and PCE, by biological consumption and volatilization.
	Compliance with applicable or relevant and appropriate requirements (ARARs)	Compliance with identified chemical-specific, location-specific and action-specific ARARs can be achieved with Alternative 3. California Department of Health Services (DHS) Policy Memo 97-005 may be applicable.
Balancing Criteria	Long-term effectiveness and permanence	Technology has not operated over long terms for perchlorate but is expected to be effective over the long term with proper operation. This alternative will partially remedy and mitigate the loss of the water supply. Reduces the potential for additional future water supply loss. Residual risk will be reduced. Treated groundwater will be pumped into an existing 102-inch raw water pipeline to obtain additional treatment. Imported water at the Rio Vista Water Treatment Plant will be displaced. Treatment system may be unavailable during recovery period following process upset.
	Reduction of mobility, toxicity, or volume through treatment	Chemical mass is removed on a "demand" basis through the treatment process. Unknown quantities of perchlorate are expected to remain in the Saugus Formation as well as in upgradient impacted areas. Contaminant mobility will be reduced through hydraulic containment.
	Short-term effectiveness	Alternative 3 can be implemented in a relative short time (2-4 years) and will be effective against the remedial action objectives immediately upon implementation. The biological treatment technology is not currently a DHS-approved technology for drinking water applications.
	Implementability	Alternative 3 can be implemented in 2-4 years. The biological treatment process is considered less reliable than ion exchange but can be monitored. Agency approvals are believed to be obtainable.
	Cost	Alternative 3 has a high estimated 30-year present value ($45.13 M) relative to Alternative 1. Alternative 3 has a lower present value than Alternative 2 and a much lower present value than Alternative 4.
Modifying Criteria	State acceptance	DHS has given a conditional approval of a fluidized bed biological reactor (FBR) system. This criterion can be further addressed and evaluated when comments are received on this Interim Remedial Action Plan (IRAP).
	Community acceptance	Community acceptance is unknown at this time. The community may be resistant to use of the biological treatment component for drinking water. This criterion can be further addressed and evaluated when comments are received on this IRAP.

Table 8: Evaluation of Alternative 2

Alternative: Ex-Situ Treatment with Ion Exchange

Description: Utilize existing water distribution infrastructure (with some modifications), construct ion exchange treatment facility, install two monitoring wells, and conduct long-term monitoring.

Evaluation Criteria		Comments
Threshold Criteria	Overall protectiveness	California Department of Health Services (DHS)-approved technology as well as the monitoring components will provide adequate protection for the water system users. Blending of treated groundwater with imported water provides additional reliability and protection of human health. Existing and continued further impacts to groundwater are reduced with Alternative 2.
	Compliance with applicable or relevant and appropriate requirements (ARARs)	Compliance with identified chemical-specific, location-specific and action-specific ARARs can be achieved with Alternative 2. DHS Policy Memo 97-005 may be applicable.
Balancing Criteria	Long-term effectiveness and permanence	Technology is proven to be effective over the long-term with proper operation. This alternative will partially remedy and mitigate the loss of the water supply. Reduces the potential for additional future water supply loss. Residual risk will be reduced. Spent resin is incinerated thus avoiding the potential for perchlorate to be transferred from one water source to another. Rio Vista Water Treatment Plant capacity for treatment of imported water not affected.
	Reduction of mobility, toxicity, or volume through treatment	Chemical mass is removed on a "demand" basis through the ion-exchange treatment process. Unknown quantities of perchlorate are expected to remain in the Saugus Formation as well as in upgradient impacted areas. Contaminant mobility reduced through hydraulic containment.
	Short-term effectiveness	Alternative 2 can be implemented in a relative short time (1-2 years) and will be effective against the remedial action objectives immediately upon implementation. The ion exchange process is already a DHS-approved technology for drinking water applications.
	Implementability	Can be implemented in 1-2 years. Construction and operation of the system is well understood. The process is reliable and can be monitored. Agency approvals are obtainable. The treatment system is available from an experienced vendor.
	Cost	Alternative 2 has high estimated 30-year present value ($51.84 M) relative to Alternative 1 and Alternative 3. Alternative 2 has a significantly lower present value than Alternative 4.
Modifying Criteria	State acceptance	Although state acceptance is unknown at this time, based upon prior state approval of ion exchange treatment for other water supplies impacted by perchlorate, it is considered likely. This criterion can be further addressed and evaluated when comments are received on this Interim Remedial Action Plan (IRAP).
	Community acceptance	Community acceptance is unknown at this time. The community is likely to accept ion exchange treatment to restore the water supply capacity. This criterion can be further addressed and evaluated when comments are received on this IRAP.

Table 7: Evaluation of Alternative 1

Alternative: No Action
Description: Installation of two monitoring wells and long-term monitoring

Evaluation Criteria		Comments
Threshold Criteria	Overall protectiveness	Provides no protection for water system users. Existing and continued further impacts to groundwater are not addressed by Alternative 1. No containment of contaminant plume. Currently unaffected downgradient wells may be impacted by contaminant plume in the future.
	Compliance with applicable or relevant and appropriate requirements (ARARs)	Alternative 1 is inconsistent with the California State Water Resources Control Board (SWRCB) Resolution 88-63 (Sources of Drinking Water Policy), SWRCB Resolution 68-16 (Non-Degradation Policy), Porter Cologne Water Quality Act, and the Water Quality Control Plan for the Los Angeles Region.
Balancing Criteria	Long-term effectiveness and permanence	The controls provided in Alternative 1 are not adequate to achieve the remedial action objectives for the reasonably foreseeable future. The residual risk that would be present as a result of implementing Alternative 1 would preclude utilization of the affected water supply.
	Reduction of mobility, toxicity, or volume through treatment	No chemical mass is removed from groundwater. No reduction of toxicity, mobility, and volume through treatment is provided with Alternative 1. No containment of contaminant plume. Currently unaffected downgradient wells may be impacted by contaminant plume in the future.
	Short-term effectiveness	Will not be effective against remedial action objectives (RAOs) upon implementation. Similar to the long-term effectiveness, the short-term controls provided in Alternative 1 are not adequate to achieve the RAOs for the near future.
	Implementability	Alternative 1 is implementable within 1 year. In addition, Alternative 1 provides the flexibility to undertake remedial actions in the future.
	Cost	Estimated 30-year present-worth cost for Alternative 1 is $1.71 M. This cost is the lowest among the alternatives discussed in this Interim Remedial Action Plan (IRAP).
Modifying Criteria	State acceptance	Although State acceptance is unknown at this time, it is considered unlikely because this alternative provides no mitigation for the perchlorate-impacted groundwater. This criterion can be further addressed and evaluated when comments are received on this IRAP.
	Community acceptance	Community acceptance is unknown at this time. However, based on the water purveyors' sense of the public water system user needs, the community would be unlikely to accept an inadequate water production capacity. This criterion can be further addressed and evaluated when comments are received on this IRAP.

Table 6: Potential ARARs and TBCs[(a)]

(a) This table describes applicable or relevant and appropriate requirements (ARARs) and material to be considered (TBCs) for the production wells impacted by perchlorate.
(b) Key for ARAR codes. The following codes indicate the agency with authority to enforce the requirement or responsible for setting the standard:

- 1. Federal
- 1a. U.S. Environmental Protection Agency
- 1b. U.S. Army Corps of Engineers
- 1c. Department of Transportation
- 1d. Occupational Safety and Health Administration
- 2. State
- 2a. California Department of Health Services
- 2b. California Regional Water Quality Control Board
- 2c. California Department of Toxic Substances Control
- 2d. California Department of Fish and Game
- 2e. California Air Resources Board
- 2f. California Department of Industrial Relations, Division of Industrial Safety
- 2g. California Resources Agency, Office of Planning and Research
- 3. Local
- 3a. South Coast Air Quality Management District
- 3b. Los Angeles County Environmental Health
- 3c. City of Santa Clarita Building Department
- 3d. City of Santa Clarita Public Works Department

(c) MCLs = maximum contaminant levels.
(d) CFR = Code of Federal Regulations.
(e) USEPA = United States Environmental Protection Agency.
(f) RCRA = Resource Conservation and Recovery Act.
(g) USC = United States Code.
(h) CCR = California Code of Regulations.

Table 6: Potential ARARs and TBCs[a]

ARAR Item	ARAR Source[b]	Statute, Regulation, Policy or Guidance	Summary of Requirements and Prerequisites	Comments	Applicability
4	1a	40 CFR 230	Actions must be taken to avoid adverse effects, minimize potential harm, and preserve and enhance wetlands, to the extent possible.	United States Army Corps of Engineers jurisdictional determination may be required to determine if the remedial action will impact wetlands.	Potentially applicable, if construction of groundwater treatment and/or conveyance facilities within a wetlands is planned.
5	1	Federal Endangered Species Act of 1973 (16 USC Section 1531 and 50 CFR Part 402) and California Endangered Species Act	Requires action to protect endangered or threatened species and their habitat		Potentially applicable if construction of groundwater treatment or conveyance facilities will impact habitat of endangered species.
6	2c	Fish and Wildlife Coordination Act (16 USC Section 661 and 40 CFR Section 6.302) (California Department of Fish and Game Code, Chapter 2, Article 1)	Impacts from activities that modify the drainage or other features of a stream or river (including wetlands) must be mitigated.		Potentially applicable if treated groundwater will be discharged to surface water or the river bed.
To Be Considered					
1	1a	USEPA Reference Dose (RfD) for Perchlorate	Used in risk assessment process to estimate acceptable concentrations of substances for specific exposure pathways	USEPA issued a draft reference dose (RfD) for perchlorate in January 2002. USEPA interim guidance provides a range of 0.0001 to 0.0005 milligrams per kilogram per day for perchlorate. In January 2004, a National Academy of Sciences committee recommended a reference dose of 0.0007 milligrams per kilogram per day of perchlorate from all sources of ingestion.	Relevant and appropriate

Table 6: Potential ARARs and TBCs[(a)]

ARAR Item	ARAR Source[(b)]	Statute, Regulation, Policy or Guidance	Summary of Requirements and Prerequisites	Comments	Applicability
VII. Other Requirements					
1	3c	Demolition, Building Permit	Demolition and/or removal of aboveground improvements on private property requires a demolition permit. Building permit required for new construction.	City permits required for demolition of any existing improvements or construction of new structures.	Potentially applicable
2	3d	Grading Permit	Grading on private property requires grading permit application with grading plans.	Permit required for any grading/earth moving activities performed during construction.	Potentially applicable
3	3d	Encroachment Permit	Construction of any aboveground or buried improvements in the public right-of-way requires an encroachment permit.	Permit required for installation of any improvements in the City of Santa Clarita public right-of-way.	Potentially applicable
4	2g	Public Resources Code Section 21000 *et seq.*; California Environmental Quality Act (CEQA)	Review of certain construction projects for environmental impacts.	Activities could be subject to the California Environmental Quality Act (CEQA) review (especially if Memo 97-005 from the California Department of Health Services (DHS) is applicable to the project).	Potentially applicable
Location-Specific ARARs					
1	1a	40 CFR Part 6		If groundwater treatment facilities are to be located within the 100-year floodplain, potential adverse effects need to be minimized.	Potentially applicable if groundwater treatment facilities will be located and constructed within the 100-year floodplain.
2	1b	Clean Water Act Section 404	Work within areas below the ordinary high water mark in an area containing a bed and bank (waterway) or areas classified as wetlands require permitting by the Federal government.	If river crossings for new pipelines involve work within wetlands or a waterway, a Federal permit may be required.	Potentially applicable.
3	2b	Clean Water Act Section 401	State agencies must certify that any activity subject to a permit issued by a federal agency meets all state water quality standards.	If river crossings for new pipelines results in fill or physical changes to state waters, 401 Certification will be required.	Potentially applicable.

Table 6: Potential ARARs and TBCs[a]

ARAR Item	ARAR Source[b]	Statute, Regulation, Policy or Guidance	Summary of Requirements and Prerequisites	Comments	Applicability
V. Health and Safety					
1	1d	Occupational Safety and Health Act (OSHA); 29 USC 641-678	Established standards for general industry safety orders.	All onsite activities need to provide adequate level of worker knowledge (i.e., hazard communication) and protection.	Applicable
2	1d	29 CFR 1910.120	Defines health and safety procedures necessary during remedial investigations and cleanup at sites where hazardous waste is/was treated, stored or disposed.	All onsite activities need to provide adequate level of worker protection (e.g., medical monitoring, job safety plans) relative to hazardous waste operational requirements.	Potentially applicable
3	2f	California Occupational Health and Safety Act (Cal-OSHA); California Labor Code, Division 5, Part 1 *et seq.*	Establishes general industry safety orders and requirements for worker health and safety at hazardous waste sites.	All onsite activities need to provide adequate level of worker knowledge (e.g., hazard communication and IIPP) and protection; must comply with requirements for hazardous waste site operations (e.g., medical monitoring, job safety plans).	Potentially applicable
VI. Water Well Standards					
1	2b	California Water Well Standards; Bulletin 74-81 and Supplement 74-90	Sets standards for construction or destruction of water wells in state.	Construction or destruction of water supply wells must follow these requirements.	Potentially applicable
2	3b	Los Angeles County Health and Safety Code Section 11.38.120	A permit to construct, repair, reconstruct, or destroy a water well should be filed.	Permits will be filed for construction or destruction of water supply wells.	Potentially applicable

Table 6: Potential ARARs and TBCs[a]

ARAR Item	ARAR Source[b]	Statute, Regulation, Policy or Guidance	Summary of Requirements and Prerequisites	Comments	Applicability
13	2a	California Department of Health Services (DHS) Policy Memo 97-005	Requires source water characterization, alternatives evaluation, risk assessment and submittal of a permit application	Applicable if production wells impacted by perchlorate are returned to service for municipal water supply.	Potentially applicable
III. Air Quality					
1	1a	Clean Air Act; 42 USC, Section 7401-7642			Applies as defined below.
2	1a	40 CFR Part 61	Sets emission standards for pollutants for which no ambient air quality standards exist, i.e. National Emissions Standards for Hazardous Air Pollutants (NESHAP).	Ambient air quality standards are available for onsite chemicals. No NESHAPs applicable.	No
3	2e	California Air Resources Act			Applies as defined below.
4	3a	17 CCR, Part III, Chapter 1, Section 60,000 *et seq.*	Sets standards for emissions from specific sources.	Treatment technologies must comply with emission standards.	Potentially applicable
5	3a	South Coast Air Quality Management District Rules and Regulations	Establishes operating and performance standards for air emissions.	Authority to construct and permit to operate required for regulated sources of air emissions. Rule on new source review of toxic air contaminants may apply.	Potentially applicable
IV. Hazardous Materials Transportation					
1	1c	Hazardous Materials Transportation Act; 44 USC 1801-1813			Applies as defined below.
2	1c	49 CFR Parts 107 and 171-177	Establishes requirements for transportation of hazardous materials (includes hazardous waste).	Applicable if any hazardous wastes are transported offsite.	Potentially applicable

Table 6: Potential ARARs and TBCs[(a)]

ARAR Item	ARAR Source[(b)]	Statute, Regulation, Policy or Guidance	Summary of Requirements and Prerequisites	Comments	Applicability
6	1a	40 CFR Parts 230	Controls certain activities that alter the waters of the United States. Establishes permitting procedures for these actions.	Filling or destruction of wetlands is a controlled activity.	Potentially applicable if construction will impacts wetlands.
7	2b	Porter-Cologne Water Quality Act; California Water Code, Division 7 and the Water Quality Control Plan for Los Angeles Region	Prohibits discharge of reportable quantity of hazardous substance or sewage to waters of the state or to locations where probable discharge may occur to any waters of the state and establishes penalties for unauthorized release.	Although it is not intended to be a consequence of water supply restoration actions in Santa Clarita, any unauthorized discharges must be appropriately reported and mitigated. Numerous existing beneficial uses of the Santa Clara River are identified in the Water Quality Plan. Any permitted discharges to the river must accommodate these uses.	Applicable
8	2a	22 CCR, Section 64630	Sets minimum separation requirements for water mains and sewer pipelines.	Requirements apply to sewer and reclaimed water pipelines, any new water distribution piping will be designed to comply with this separation requirement.	Potentially applicable
9	2b	23 CCR, Chapter 15	Activities must maintain beneficial uses of state waters. Sets standards for waste and site classifications and waste management requirements for waste treatment, storage, or disposal in landfills; surface impoundments; waste piles; and land treatment facilities.	Remedial activities must maintain beneficial use of state waters and must meet standards for discharge of wastes to land.	Potentially applicable
10	2d	California Department of Fish and Game (DFG), Chapter 2, Article 1	Impacts from activities that modify the drainage or other features of a stream or river (including wetlands) must be mitigated.		Potentially applicable if treated groundwater will be discharged to surface water or the river bed.
11	2a	22 CCR Sections 64431, 64439, 64441, 64443, 64444, and 64449	Establishes drinking water standards and monitoring requirements for public water supply systems		Applicable
12	2a	Health and Safety Code 116525 *et seq.*, 22 CCR Chapter 14	Sets requirements for technical reports, application review, public hearings and changes to domestic water supply permit		Applicable

Table 6: Potential ARARs and TBCs[a]

ARAR Item	ARAR Source[b]	Statute, Regulation, Policy or Guidance	Summary of Requirements and Prerequisites	Comments	Applicability
10	2c	22 CCR, Division 4.5, Chapter 20	Establishes provisions covering basic permitting requirements for onsite hazardous waste treatment, storage, and disposal facilities (TSDFs).	The California Department of Toxic Substances' (DTSC's) general policy is that permits are not required for hazardous waste corrective actions at sites with an approved Remedial Action Plan (RAP). Offsite landfills must have current permits.	No
II. Water Quality					
1	1a	Federal Underground Injection Control Program 40 CFR Parts 144-147	Establishes procedural and permitting standards for underground injection to protect underground sources of drinking water.	Requirements are applicable if reinjection wells are proposed to enhance groundwater restoration.	Potentially applicable
2	1a	Clean Water Act; 33 USC 1251-1376			Applies as defined below.
3	1a	40 CFR Parts 122 and 125	Establishes permitting standards (including numeric criteria) for discharge of pollutants from any point source into waters of the United States based on ambient water quality criteria, i.e. the National Pollutant Discharge Elimination System (NPDES).	Requirements are applicable if discharge of groundwater to storm drain or surface water is implemented.	Potentially applicable
4	1a	40 CFR Part 403	Establishes national pretreatment standards to control pollutants that pass through or interfere with treatment processes in publicly-owned treatment works (POTWs) or that may contaminate sewage sludge.	Requirements are applicable if discharge of groundwater or treatment residuals to sanitary sewer is implemented.	Potentially applicable
5	1a	40 CFR Part 129	Establishes toxic pollutant effluent standards for certain toxic pollutants (i.e., presence of aldrin, dieldrin, dichlorodiphenyltrichloroethane, endrin, toxaphene, benzidine, polychlorinated biphenyls) in effluent.	Discharge of these chemicals is not anticipated.	No

Table 6: Potential ARARs and TBCs[a]

ARAR Item	ARAR Source[b]	Statute, Regulation, Policy or Guidance	Summary of Requirements and Prerequisites	Comments	Applicability
5	2c	22 CCR, Division 4.5, Chapter 12	Establishes standards for generators of hazardous waste. Generators of hazardous waste must comply with standards in 22 CCR 66265 regarding waste analysis; contingency planning, preparedness and prevention; personnel training; management of hazardous waste in containers and tanks; and, decontamination of residues, contaminated containment system components, containment structures and equipment at closure.	Applicable if hazardous wastes are generated as a result of groundwater treatment or additional well installation activities.	Potentially applicable
6	2c	22 CCR, Division 4.5, Chapter 13	Establishes standards that apply to persons transporting hazardous waste within California.	Applicable if hazardous waste must be transported offsite for recycling, treatment, or disposal.	Potentially applicable (if offsite shipment is necessary, waste will be transported by a contracted, licensed hauler).
7	2c	22 CCR, Division 4.5, Chapter 14	Establishes minimum state permitting standards that define the acceptable management of hazardous waste for owners and operators of facilities that treat, store or dispose of hazardous waste.	Applicable if onsite activities involve methods that meet the definitions of treatment, storage or disposal of hazardous waste.	Potentially applicable
8	2c	22 CCR, Division 4.5, Chapter 16	Establishes requirements that apply to recyclable materials that are reclaimed to recover economically significant amounts of precious metals and waste oil.	Recovery of precious metals or waste oil is not anticipated as part of onsite remedial activities.	No
9	2c	22 CCR, Division 4.5, Chapter 18	Land Disposal Restrictions. Prohibits land disposal of specified untreated RCRA hazardous wastes and non-RCRA hazardous wastes and provides special requirements for handling such wastes.	Applicable if listed or characteristic hazardous wastes, as defined in 22 CCR, Division 4.5, Chapter 11, or restricted non-RCRA wastes are generated and disposed.	Potentially applicable

Table 6: Potential ARARs and TBCs[(a)]

ARAR Item	ARAR Source[(b)]	Statute, Regulation, Policy or Guidance	Summary of Requirements and Prerequisites	Comments	Applicability
5	2b	Porter Cologne Water Quality Control Act and the Water Quality Control Plan for Los Angeles Region	Porter Cologne authorizes the State Board and the Regional Board to establish water quality control plans for surface and groundwater within the state/region. The portions of the Water Quality Control Plan for the Los Angeles Region that identify designated uses and associated water quality criteria are applicable.	The Water Quality Control Plan specifies that existing beneficial uses of the Saugus Formation groundwater include municipal water supply.	Applicable
Action-Specific ARARs					
1	1a	RCRA[(f)]; 42 USC[(g)] 6901-6987; Subtitle C and California Health and Safety Code			Applies as defined below
2	1a	40 CFR 260	Establishes standards for generators, transporters, and owners/operators of treatment, storage and disposal facilities. Provides definitions and general standards applicable to Parts 260-265, 268.	If wastes are generated as a result of treatment or additional well installation activities that are considered hazardous, requirements of 40 CFR, Parts 260-265, 268 may be ARARs.	Potentially applicable
3	1a	40 CFR 264, Subpart 5	Sets standards for definition and use of corrective action management units (CAMUs) for implementing corrective actions under RCRA.	Onsite disposal not anticipated.	No
4	2c	22 CCR[(h)], Division 4.5, Chapter 11	Establishes/defines procedures and criteria for identification and listing of RCRA and non-RCRA hazardous wastes.	If wastes are generated and are RCRA listed or characteristic hazardous wastes or non-RCRA hazardous wastes, requirements of 22 CCR, Division 4.5, Chapters 12 to 18 may be ARARs.	Potentially applicable

Table 6: Potential ARARs and TBCs[a]

ARAR Item	ARAR Source[b]	Statute, Regulation, Policy or Guidance	Summary of Requirements and Prerequisites	Comments	Applicability
Chemical-Specific ARARs					
1	1a	Federal Safe Drinking Water Act MCLs[c] (40 CFR[d] 141-143)	MCLs have been developed to regulate the concentrations of contaminants in public drinking water supplies. MCLs are legally enforceable.	An MCL has not been developed yet for perchlorate, however, MCLs have been developed for other contaminants that are present in Saugus Formation groundwater.	Applicable
2	2a	California Safe Drinking Water Act (California Health and Safety Code 116272 *et. seq.*)	California has developed MCLs that may be more stringent than federal MCLs, and has set MCLs for contaminants not yet regulated by USEPA[e].	If the state MCL is more stringent (lower) than the federal MCL, the state MCL will govern. A state MCL has not yet been developed for perchlorate. The state has identified an advisory "action level" of 6 micrograms per liter of perchlorate in drinking water.	Applicable
3	2b	California State Water Resources Control Board Resolution 88-63 (Sources of Drinking Water Policy)	Designates all groundwater within the state as a potential source of drinking water except where the total dissolved solids concentration in groundwater exceeds 3,000 parts per million or the well yield from a single well is less than 200 gallons per day.	Prior to identification of the perchlorate impact, water was pumped from the four production wells for municipal supply, including drinking water.	Applicable
4	2b	California State Water Resources Control Board Resolution 68-16 (Non-Degradation Policy)	This policy calls for maintaining the existing high quality of the state's water unless it is demonstrated that any change would be consistent with maximum public benefit and not unreasonably affect beneficial uses.		Relevant

Table 5: Chemical-Specific ARARs and TBCs[(a)]

(a) This table presents chemical concentrations for groundwater specified in applicable or relevant and appropriate requirements (ARARs) or other material to be considered (TBCs) for the production wells impacted by perchlorate. This table lists chemical-specific ARARs for perchlorate and organic compounds detected in any one groundwater sample.
(b) µg/l = micrograms per liter.
(c) MCL = primary maximum contaminant level from Title 22, California Code of Regulations, Sections 64439 and 64444.
(d) PHG = public health goal from the California Office of Environmental Health Hazard Assessment (OEHHA).
(e) AL = action level (health-based advisory concentration for unregulated contaminants in drinking water) from the California Department of Health Services (DHS).
(f) MCL from the federal Safe Drinking Water Act. Title 40, Code of Federal Regulations, Parts 141-143.
(g) MCLGs = maximum contaminant level goals (non-enforceable public health goals based upon public health, which do not account for economic or technology limitations) from the Safe Drinking Water Act.
(h) National Pollutant Discharge Elimination System (NPDES) criteria, which apply to discharge of pollutants to surface waters, as specified in California Regional Water Quality Control Board, Los Angeles Region Order Number R4-2002-0107 Waste Discharge Requirements for Discharges of Treated Groundwater From Investigation and/or Cleanup of Volatile Organic Compounds Contaminated Sites to Surface Waters in Coastal Watersheds of Los Angeles and Ventura Counties (General NPDES Permit Number CAG914001).
(i) "–" = no concentration limit established.
(j) The California MCL is 100 µg/l total trihalomethanes (TTHMs), defined as the sum of chloroform, bromoform, bromodichloromethane and dibromochloromethane.
(k) Average monthly effluent limit / maximum daily effluent limit.
(l) Primary MCL / secondary MCL.

Table 5: Chemical-Specific ARARs and TBCs[a]

Table 4: Summary of Human Health Risks Associated with Contaminated Groundwater from the Saugus Formation Production Wells

Exposure Medium	Exposure Scenario	Noncancer Hazard Quotient	Preliminary Remediation Goal (µg/l)[(a)]	Primary Exposure Pathway
Groundwater	Adult Resident	4.4	6	Ingestion of well water containing perchlorate
Groundwater	Child Resident	10.4	6	Ingestion of well water containing perchlorate

(a) µg/l = micrograms per liter.
(b) Shaded cells represent noncancer hazards that exceed California Department of Toxic Substances Control (DTSC) target levels.

Table 3: Determination of Chemicals of Potential Concern

Chemical Abstracts Service Registry Number	Chemical[a]	Maximum Detected Concentration (µg/l)[b]	Range of Detected Concentrations (µg/l)	Location of Maximum[c]	Maximum Contaminant Level/Notification Level (µg/l)[d]	Chemical of Potential Concern?
7440-66-6	Zinc – Dissolved	31	6.7 - 31	NC-11	5,000	NO

GROUNDWATER GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	SCREENING COMMENTS
No Action	None	None	No remedial action taken. No operation of production wells.	National Contingency Plan requires consideration of this alternative.
Institutional Action	Proprietary Controls	Land purchase	Purchase of land to construct facilities, prevent use, or control selected remedy.	Potentially applicable in conjunction with other process options.
		Deed restrictions	Legally enforceable land use restrictions on current and future property owners.	Potentially applicable in conjunction with other process options.
		Deed notices	Public land record document providing information about the property. Non-enforceable.	Potentially applicable in conjunction with other process options.
		Easements	Limited property rights conveyed to a party by the landowner(s).	Potentially applicable in conjunction with other process options.
		Covenants	Legal agreements between landowners concerning land use.	Potentially applicable in conjunction with other process options.
	Governmental Controls	Land use restrictions	Restrictions on the use of land issued by a governmental jurisdiction.	Potentially applicable for well siting restrictions in conjunction with other process options.
		Groundwater use restrictions	Includes California Department of Health Services (DHS) oversight of public water systems.	Likely to be applicable for the scope of this Interim Remedial Action Plan (IRAP).
		Advisories	Risk communication regarding use of groundwater via public notices.	Potentially applicable in conjunction with other process options.
Monitoring	Monitoring	Groundwater monitoring	Monitoring of groundwater on a short-term and long-term basis to assess migration rates and contaminant levels.	Likely to be applicable in conjunction with other process options.
		Public water system	Monitoring of the public water system to assess exposure risk.	Likely to be applicable for the scope of this IRAP.
Alternative/Replacement Water Supply	Alternative/Replacement Water Supply	New water supply well	New non-impacted production wells supplement and/or replace existing wells.	Potentially applicable.
		New water supply	New non-impacted water supply source supplement and/or replace existing wells. Includes imported water, water trades, new surface water supply, direct and indirect reuse.	Potentially applicable.
Monitored Natural Attenuation	Monitoring/Verification	Groundwater monitoring	Natural attenuation by biodegradation, dispersion, dilution, and adsorption. Involves long-term monitoring and contingencies.	Potentially applicable in conjunction with other process options.

INITIAL TECHNICAL IMPLEMENTABILITY SCREENING OF TECHNOLOGIES AND PROCESS OPTIONS

DECEMBER 2005
K/J 034803.00
Figure 4

GROUNDWATER GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	SCREENING COMMENTS
Ex Situ Treatment	Ex Situ Physical Treatment	LPGAC	Liquid-phase granular activated carbon (LPGAC) used as adsorbent media to adsorb chemicals from liquid phase stream.	Approved by the DHS for short-term, site-specific use for perchlorate. Potentially applicable for short-term sampling events. It is unlikely to be approved for long-term use.
		Air Stripping	Mass transfer from liquid to vapor phase usually using countercurrent air through a packed tower.	Not applicable for perchlorate.
		Filtration	Single or multi-media filters remove particulates from liquid phase stream.	Potentially applicable in conjunction with other treatment process options.
		Membrane separation	Chemicals are separated from water as the water is passed through semi-permeable membranes. Examples include reverse osmosis, nanofiltration, ultra filtration, and electrodialysis.	Potentially applicable for perchlorate. Pilot-scale testing is underway.
	Ex Situ Chemical Treatment	Ion exchange	Ions are exchanged in solution as water is passed through a bed of resin. Regeneration or disposal of loaded resin is required.	Potentially applicable for perchlorate. Process has been tested full scale and is a DHS-approved technology for drinking water.
		Ultraviolet irradiation/chemical oxidation	Oxidation of chemicals is promoted through the use of ultraviolet light. May include introduction of hydrogen peroxide.	Not applicable for perchlorate.
		Pre-loaded GAC	Use of granular activated carbon (GAC) preloaded with metal complexes for removal of perchlorate. Requires regeneration.	Approved by the DHS for short-term, site-specific use for perchlorate. Potentially applicable for short-term sampling events. Recent research indicates potential for long-term use. However, it is unlikely to be approved for long-term use within time frame of this project.
		Electrochemical processes	Oxidation state of ions is changed in solution by application of an electrical current.	Not applicable for perchlorate.
		Aeration of metals	Chemical oxidation and hydroxide formation are promoted by aeration.	Not applicable for perchlorate.
		Reactive metals aboveground reactor	COPCs destroyed in an aboveground reactor as water is passed through a bed of reactive metal media.	Not applicable for perchlorate.
		pH adjustment	pH is adjusted through the introduction of acid or caustic. Usually in conjunction with another process.	Potentially applicable in conjunction with other treatment process options.
	Ex Situ Biological Treatment	Aerobic bioreactors	Fixed or fluidized bed reactors contain aerobic microorganisms whereby organics are biologically assimilated and transformed.	Potentially applicable but not a DHS-approved technology for drinking water.
		Cometabolic anaerobic bioreactors (biological reduction)	Organic substrates such as ethanol and nutrients are used as an amendment to perchlorate-impacted water that is passed through a GAC/fluidized bed reactor.	Potentially applicable for perchlorate but is not a DHS-approved technology for drinking water.
		Anaerobic bioreactors	Reactor contains anaerobic microorganisms whereby organics and perchlorate are biologically assimilated and transformed.	Not applicable for perchlorate in absence of organic substrate.

K/J 034803.00
Figure 4

GROUNDWATER GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	DESCRIPTION	SCREENING COMMENTS
Management/Reuse of Groundwater	Treated Groundwater Management	Direct potable water supply	Water purveyors provide treated water directly to the distribution system.	Potentially applicable.
		Indirect potable water supply	Treated water is discharged to surface water.	Potentially applicable.
		Non-potable water reuse	Treated water used for irrigation and/or industrial use.	Potentially applicable.
		Streamflow augmentation	Treated water discharged directly or indirectly to surface water.	Potentially applicable.
		Discharge to publicly owned treatment works (POTW)	Treated water discharged to sanitary sewer.	Potentially applicable.
		Groundwater recharge	Treated water recharged to the aquifer.	Potentially applicable.
		Deep well injection	Treated water injected into a deep aquifer	Potentially applicable.
	Untreated Groundwater Management	Discharge to POTW	Untreated water discharged to sanitary sewer.	Potentially applicable.
		Deep well injection	Untreated water injected into a deep aquifer	Potentially applicable.
		Streamflow augmentation	Untreated water discharged directly or indirectly to surface water.	Potentially applicable.

INITIAL TECHNICAL IMPLEMENTABILITY SCREENING OF TECHNOLOGIES AND PROCESS OPTIONS

DECEMBER 2005
K/J 034803.00
Figure 4

GROUNDWATER GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST
No Action	None	None	Will not achieve Remedial Action Objectives (RAOs).	Potentially implementable.	No implementation cost. Potential uncertain cost impacts to local economy based on expected water shortages.
Institutional Controls	Proprietary Controls	Land purchase	Will not achieve RAOs alone. Not effective for restoration of water supply except as siting for treatment facilities.	Land purchase requires negotiation with current landowners.	High cost associated with land valuations in area.
		Deed restrictions	Will not achieve RAOs. Not effective for restoration of water supply.	Potentially implementable.	Low costs.
		Deed notices	Will not achieve RAOs. Not effective for restoration of water supply.	Potentially implementable.	Low costs.
		Easements	Will not achieve RAOs. Not effective for restoration of water supply except as siting for treatment facilities.	Procuring easement requires negotiation with current landowners or government agency.	Low to moderate costs depending on scope of easement negotiation.
		Covenants	Will not achieve RAOs. Not effective for restoration of water supply.	Potentially implementable.	Low costs.
	Governmental Controls	Land use restrictions	Will not achieve RAOs. Not effective for restoration of water supply except as siting for treatment facilities.	Potentially implementable. May involve difficult negotiations.	Low to high costs depends on scope of restrictions.
		Groundwater use restrictions	Will not achieve RAOs. Not effective for restoration of water supply.	Potentially implementable.	Low costs.
		Advisories	Will not achieve RAOs. Not effective for restoration of water supply.	Potentially implementable.	Low costs.
Monitoring	Monitoring	Groundwater monitoring	Will not achieve RAOs alone. Not effective for restoration of water supply. Effective in tracking presence and movement of chemicals in groundwater.	Potentially implementable.	Low to moderate costs.
		Public water system	Will not achieve RAOs alone. Not effective for restoration of water supply. Effective in establishing the presence of chemicals in groundwater.	Potentially implementable.	Low to moderate costs.
Alternative/Replacement Water Supply	Alternative/Replacement Water Supply	New water supply wells	Effective for restoration of water supply and preventing exposures over a relative short term. Proper well siting is important in long-term effectiveness. May be some influence on plume migration.	Potentially implementable. Well sites must be identified. May involve possible land purchase and/or easements.	Moderate to high capital costs.
		New water supply: • Inter-ties • Direct reuse of treated groundwater • Indirect reuse of treated groundwater • New surface water supply	Limited effectiveness for restoration of water supply and preventing exposures over a relative short term. Particularly limited during drought conditions when back-up supply is needed.	Potentially implementable on a limited basis. Source of water must be identified. New surface water supply will involve long-term surface water entitlements and possibly a new water treatment facility.	Moderate to high costs.

EVALUATION OF TECHNOLOGIES AND PROCESS OPTIONS

DECEMBER 2005
K/J 034803.00
Figure 5

GROUNDWATER GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST
Monitored Natural Attenuation	Monitoring/Verification	Groundwater monitoring	Will not achieve RAOs alone. Not effective for restoration of water supply in short term. Potential limited long-term effectiveness. Will not protect downgradient water resources.	Potentially implementable.	Low to moderate cost.
Containment	Hydraulic Barriers	Vertical extraction wells	Will not achieve RAOs alone. Effective, proven technology for containing plume migration. Proper well siting is important in long-term effectiveness.	Potentially implementable. Well sites must be identified. May involve possible land purchase and/or easements.	Moderate to high costs.
		Extraction and recharge wells	Will not achieve RAOs alone. Effective, proven technology for containing plume migration and providing hydraulic control. Proper extraction and recharge siting is important in long-term effectiveness. Not effective for restoration of water supply in the short-term.	Potentially implementable. Extraction and recharge sites must be identified. May involve possible land purchase and/or easements.	High costs.
Collection	Groundwater Extraction	Vertical groundwater extraction wells	Will not achieve RAOs alone. Effective, proven technology for groundwater extraction. Proper well siting is important in long-term effectiveness.	Potentially implementable. Well sites must be identified. May involve possible land purchase and/or easements.	Moderate to high costs.
		Recharge wells	Will not achieve RAOs alone. Effective, proven technology for flushing and improved flow. Proper recharge siting is important in long-term effectiveness. Not effective for restoration of water supply in the short-term.	Potentially implementable. Recharge sites must be identified. May Involve possible land purchase and/or easements.	High costs.
In Situ Treatment	Biological Treatment	Enhanced biological reduction	Will not achieve RAOs alone. Effectiveness has not been confirmed. Pilot testing in progress at an unrelated site.	Potentially implementable. Nutrient introduction locations must be identified. May involve possible land purchase and/or easements. Not currently a California Department of Health Services (DHS) approved technology for drinking water.	Moderate costs.

EVALUATION OF TECHNOLOGIES AND PROCESS OPTIONS

DECEMBER 2005
K/J 034803.00
Figure 5

GROUNDWATER GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST
Liquid Phase Treatment	Ex Situ Physical/Chemical Treatment	Filtration	Effective for removal of particulates as part of a treatment train designed to remove perchlorate. Must be implemented in conjunction with a containment/collection process.	Potentially implementable.	Low to moderate cost.
		Membrane separation	Effective for removal of perchlorate. Must be implemented in conjunction with a containment/collection process.	Implementable. Process is currently being tested experimentally.	High capital and O&M costs.
		Ion exchange	Effective for removal of perchlorate. Must be implemented in conjunction with a containment/collection process.	Implementable. Process has been tested full-scale, is operating at several locations, and is currently the only DHS-approved technology for drinking water.	Moderate to high capital and O&M costs.
		pH adjustment	Effective for pH adjustment as part of a treatment train designed to remove perchlorate. Must be implemented in conjunction with a containment/collection process.	Potentially implementable.	Low costs.
	Ex Situ Biological Treatment	Aerobic bioreactor	Not effective for removal of perchlorate. Must be implemented in conjunction with a containment/collection process.	Difficult to implement.	Moderate to high capital and O&M costs.
		Cometabolic anaerobic bioreactor (biological reduction)	Effective for removal of perchlorate. Must be implemented in conjunction with a containment/collection process.	Difficult to implement. Not a DHS-approved technology for drinking water.	Moderate to high capital and O&M costs.

LEGEND

- (open box) Potentially effective, implementable, and cost-effective Technology or Process Option.
- (hatched box) Technology and/or Process Option screened out on the basis of effectiveness, implementability, and/or costs.
- (shaded box) Process Option considered innovative.

EVALUATION OF TECHNOLOGIES AND PROCESS OPTIONS

DECEMBER 2005
K/J 034803.00
Figure 5

GROUNDWATER GENERAL RESPONSE ACTION	REMEDIAL TECHNOLOGY	PROCESS OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST
Management/Reuse of Groundwater	Treated Groundwater Management	Direct potable supply	May potentially achieve RAOs alone. Effective when treated water meets drinking water standards.	Potentially implementable. DHS-approval required.	Low cost assuming no further treatment.
		Indirect potable supply	Will not achieve RAOs alone. Effective when treated water meets discharge standards.	Potentially implementable. National Pollutant Discharge Elimination System (NPDES) permit may be required.	Low to moderate cost assuming no further treatment.
		Non-potable water reuse	Will not achieve RAOs alone. May be relevant to management of groundwater not needed for water supply. Effective when treated water meets beneficial reuse standards.	Potentially implementable. Demand may fluctuate.	Low to moderate cost assuming no further treatment.
		Stream flow augmentation	Will not achieve RAOs alone. Effective when treated water meets discharge standards. Not effective for restoration of lost production capacity.	Potentially implementable. NPDES permit may be required.	Low to moderate cost assuming no further treatment.
		Discharge to publicly owned treatment works (POTW)	Will not achieve RAOs alone. May be relevant to management of groundwater not needed for water supply.	Potentially implementable. Connection permit may be required.	Low to moderate cost assuming no further treatment.
		Groundwater recharge	Will not achieve RAOs alone. Not effective for restoration of lost production capacity.	Potentially implementable. Discharge permit may be required.	Low to moderate cost assuming no further treatment.
		Deep well injection	Will not achieve RAOs alone. Not effective for restoration of lost production capacity.	Potentially implementable. Discharge permit may be required.	Moderate cost assuming no further treatment.
	Untreated Groundwater Management	Discharge to POTW	Will not achieve RAOs alone. Relevant for management of untreated groundwater not needed for water supply.	Unlikely to be approved and permitted for implementation.	Low to moderate cost assuming no further treatment.
		Deep well injection	Will not achieve RAOs.	Difficult to implement.	Moderate cost.
		Streamflow augmentation	Will not achieve RAOs alone. Relevant for management of untreated groundwater not needed for water supply	Unlikely to be approved and permitted for implementation.	Low to moderate cost assuming no further treatment.

NOTES:

Units in **micrograms per liter (µg/L)**, unless otherwise noted.

Analytes listed in this table have one or more samples with concentrations reported above their quantitation limits.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
NT = Not tested
OEHHA = Office of Environmental Health Hazard Assessment
PHG = Public Health Goal (for Drinking Water)
QA = Quality Assurance
USACE = U.S. Army Corps of Engineers
USEPA = U.S. Environmental Protection Agency

(1) CA Primary MCL for total trihalomethanes (bromodichloromethane, bromoform, dibromochloromethane, and chloroform).
(2) USEPA Primary MCL for total trihalomethanes (bromodichloromethane, bromoform, dibromochloromethane, and chloroform).

Data Qualifiers:
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.
UJ = Analyte not detected above the quantitation limit, but the reported quantitation limit is approximate.

(bromodichloromethane, bromoform, dibromochloromethane, and chloroform).
(2) USEPA Primary MCL for total trihalomethanes
(bromodichloromethane, bromoform, dibromochloromethane, and chloroform).

Data Qualifiers:
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.
UJ = Analyte not detected above the quantitation limit, but the reported quantitation limit is approximate.

NOTES:

Units in **micrograms per liter (µg/L)**, unless otherwise noted.

Analytes listed in this table have one or more samples with concentrations reported above their quantitation limits.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
NT = Not tested

OEHHA = Office of Environmental Health Hazard Assessment
PHG = Public Health Goal (for Drinking Water)
QA = Quality Assurance
USACE = U.S. Army Corps of Engineers
USEPA = U.S. Environmental Protection Agency

(1) CA Primary MCL for total trihalomethanes (bromodichloromethane, bromoform, dibromochloromethane, and chloroform).
(2) USEPA Primary MCL for total trihalomethanes (bromodichloromethane, bromoform, dibromochloromethane, and chloroform).

Data Qualifiers:
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.
UJ = Analyte not detected above the quantitation limit, but the reported quantitation limit is approximate.

NOTES:

Units in **micrograms per liter (µg/L)**, unless otherwise noted.

Analytes listed in this table have one or more samples with concentrations reported above their quantitation limits.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
NT = Not tested

OEHHA = Office of Environmental Health Hazard Assessment
PHG = Public Health Goal (for Drinking Water)
QA = Quality Assurance
USACE = U.S. Army Corps of Engineers
USEPA = U.S. Environmental Protection Agency

(1) CA Primary MCL for total trihalomethanes
(bromodichloromethane, bromoform, dibromochloromethane, and chloroform).
(2) USEPA Primary MCL for total trihalomethanes
(bromodichloromethane, bromoform, dibromochloromethane, and chloroform).

Data Qualifiers:
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.
UJ = Analyte not detected above the quantitation limit, but the reported quantitation limit is approximate.

NOTES:

Units in **micrograms per liter (µg/L)**, unless otherwise noted.
Analytes listed in this table have one or more samples with concentrations reported above their quantitation limits.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
NT = Not tested
OEHHA = Office of Environmental Health Hazard Assessment
PHG = Public Health Goal (for Drinking Water)
QA = Quality Assurance
USACE = U.S. Army Corps of Engineers
USEPA = U.S. Environmental Protection Agency

(1) CA Primary MCL for total trihalomethanes
(bromodichloromethane, bromoform, dibromochloromethane, and chloroform).
(2) USEPA Primary MCL for total trihalomethanes
(bromodichloromethane, bromoform, dibromochloromethane, and chloroform).

Data Qualifiers:
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.
UJ = Analyte not detected above the quantitation limit, but the reported quantitation limit is approximate.

NOTES:

Units in **micrograms per liter (µg/L)**, unless otherwise noted.
Analytes listed in this table have one or more samples with concentrations reported above their quantitation limits.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
NT = Not tested
OEHHA = Office of Environmental Health Hazard Assessment
PHG = Public Health Goal (for Drinking Water)
QA = Quality Assurance
USACE = U.S. Army Corps of Engineers
USEPA = U.S. Environmental Protection Agency

(1) CA Primary MCL for total trihalomethanes
(bromodichloromethane, bromoform, dibromochloromethane, and chloroform).
(2) USEPA Primary MCL for total trihalomethanes
(bromodichloromethane, bromoform, dibromochloromethane, and chloroform).

Data Qualifiers:
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.
UJ = Analyte not detected above the quantitation limit, but the reported quantitation limit is approximate.

NOTES:

Units in **micrograms per liter (µg/L).**

Analytes listed on this table have 1 or more samples with concentrations reported above their quantitation limits.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
ft bgs = feet below ground surface

MCL = Maximum Contaminant Level
OEHHA = Office of Environmental Health Hazard Assessment
PHG = Public Health Goal (for Drinking Water)
USEPA = U.S. Environmental Protection Agency

(1) CA Primary MCL for total trihalomethanes (bromodichloromethane, bromoform, dibromochloromethane, and chloroform).

(2) USEPA Primary MCL for total trihalomethanes (bromodichloromethane, bromoform, dibromochloromethane, and chloroform).

Data Qualifiers:

B = Analyte detected in trip blank sample.
BJ = Estimated value; compound is found in the associated blank as well as in the sample.
J = Analyte positively identified; the reported concentration is approximate.
U = Analyte not detected above quantitation limit.

(This Page Intentionally Blank)

NOTES:

Units in **micrograms per liter (µg/L).**
Results for all metals and cyanide are listed in this table.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
NT = Not tested
OEHHA = Office of Environmental Health Hazard Assessment
PHG = Public Health Goal (for Drinking Water)
QA = Quality Assurance
USACE = U.S. Army Corps of Engineers
USEPA = U.S. Environmental Protection Agency

(1) Chromium (VI) is currently regulated under the MCL for total chromium.
(2) The USEPA Primary MCL of 10 µg/L is effective on January 23, 2006.

Data Qualifiers:
B = Analyte was found in associated method blank as well as in sample above QC level.
E = Result is above the maximum calibration range.
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.
UJ = Analyte not detected above the quantitation limit, but the reported quantitation limit is approximate.

Cyanide	150	200			150		NT	10 U	NT	NT	10 U	10 U	NT

NOTES:

Units in **micrograms per liter (µg/L).**
Results for all metals and cyanide are listed in this table.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
NT = Not tested
OEHHA = Office of Environmental Health Hazard Assessment
PHG = Public Health Goal (for Drinking Water)
QA = Quality Assurance
USACE = U.S. Army Corps of Engineers
USEPA = U.S. Environmental Protection Agency

(1) Chromium (VI) is currently regulated under the MCL for total chromium.
(2) The USEPA Primary MCL of 10 µg/L is effective on January 23, 2006.

Data Qualifiers:
B = Analyte was found in associated method blank as well as in sample above QC level.
E = Result is above the maximum calibration range.
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.
UJ = Analyte not detected above the quantitation limit, but the reported quantitation limit is approximate.

NOTES:

Units in **micrograms per liter (µg/L).**
Results for all metals and cyanide are listed in this table.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
NT = Not tested
OEHHA = Office of Environmental Health Hazard Assessment
PHG = Public Health Goal (for Drinking Water)
QA = Quality Assurance
USACE = U.S. Army Corps of Engineers
USEPA = U.S. Environmental Protection Agency

(1) Chromium (VI) is currently regulated under the MCL for total chromium.
(2) The USEPA Primary MCL of 10 µg/L is effective on January 23, 2006.

Data Qualifiers:
B = Analyte was found in associated method blank as well as in sample above QC level.
E = Result is above the maximum calibration range.
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.
UJ = Analyte not detected above the quantitation limit, but the reported quantitation limit is approximate.

Gross Alpha	15 pCi/L	15 pCi/L					NT	6.43±2.39	NT	8.44±2.72	NT	4.67±2.42
Gross Beta	50 pCi/L	4 mrem/yr					NT	6.7±1.62	NT	6.03±1.63	NT	1.3±1.18

NOTES:

Units in **milligrams per liter (mg/L)**, unless otherwise noted.
Results for all inorganics other than metals, general parameters, and gross alpha/gross beta are listed in this table.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
mrem/yr = millirem per year
NT = Not tested
OEHHA = Office of Environmental Health Hazard Assessment
pCi/L = picocurie per liter
PHG = Public Health Goal (for Drinking Water)
USEPA = U.S. Environmental Protection Agency

Data Qualifiers:
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.

NOTES:

Units in **milligrams per liter (mg/L)**, unless otherwise noted.

Results for all inorganics other than metals, general parameters, and gross alpha/gross beta are listed in this table.

AL = Action Level (for toxicity)
CA = California
DHS = Department of Health Services
MCL = Maximum Contaminant Level
mrem/yr = millirem per year
NT = Not tested
OEHHA = Office of Environmental Health Hazard Assessment
pCi/L = picocurie per liter
PHG = Public Health Goal (for Drinking Water)
USEPA = U.S. Environmental Protection Agency

Data Qualifiers:
J = Analyte positively identified; the reported concentration is approximate.
R = Rejected due to deficiencies in the ability to analyze the sample and/or meet quality control criteria.
U = Analyte not detected above quantitation limit.

- MODEL LAYER 2
- MODEL LAYER 3
- MODEL LAYER 4
- MODEL LAYER 5
- WHITTAKER-BERMITE PROPERTY BOUNDARY

NOTES:

1. VALUES PRESENTED UNDER WELL SYMBOLS REPRESENT PERCHLORATE CONCENTRATION IN GROUNDWATER (μg/L).
2. INDICATED PUMPING RATES REPRESENT INSTANTANEOUS RATES WHEN THE WELL OPERATES.
3. ND = PERCHLORATE NOT DETECTED IN GROUNDWATER SAMPLE.
4. μg/L = MICROGRAMS PER LITER; gpm = GALLONS PER MINUTE
5. FLOWPATHS AT VWC-157 AND MP-5 ARE INITIATED IN MODEL LAYERS 2, 3, 4, AND 5. FLOWPATHS AT THE WHITTAKER-BERMITE PROPERTY BOUNDARY ARE INITIATED IN MODEL LAYER 3.
6. FLOWPATHS ARE DELINEATED USING AN EFFECTIVE POROSITY OF 0.10 IN THE ALLUVIAL AQUIFER AND THE SAUGUS FORMATION.

Cost Analysis

Table C-12: Alternative 4 Present Value Analysis

Alternative: Membrane Filtration
Site: Production Wells
Location: Santa Clarita, California
Phase: Planning (-30% to +50% accuracy)
Base Year: 2004

Description: Utilization of existing water distribution system with some modifications and additions, membrane filtration treatment with 2,400 gpm capacity, discharge of treated water into existing 84-inch treated water distribution pipeline, abandon Wells NC-11 & V-157. Capital costs occur in Year 0. Annual O&M costs occur in Years 1-30.

Year	Capital Costs	Annual O&M Costs	Period Costs	Total Costs	Cost Factor:	Present Value
0	$ 19,703,426	$ -	$ -	$ 19,703,426	1.000	$ 19,703,426

Total	$ 19,703,426	$ 87,073,070	$ -	$ 106,776,496		$ 73,083,378

Total Present Value of Alternative 4 **$ 73,083,378**

Notes:

1. Real discount rate (base year 2004): 3.5%
   As indicated for a 30-year maturity in Circular A94: Guidelines and Discount Rates for Benefit-Cost Analysis of Federal Programs. http://www.whitehouse.gov/omb/circulars/a094/a094.html

Table C-11: Alternative 4 Annual O&M Costs

Alternative: Membrane Filtration
Site: Production Wells
Location: Santa Clarita, California
Phase: Planning (-30% to +50% accuracy)
Base Year: 2004

Description: Utilization of existing water distribution system with some modifications and additions, membrane filtration treatment with 2,400 gpm capacity, discharge of treated water into existing 84-inch treated water distribution pipeline, abandon Wells NC-11 & V-157. Capital costs occur in Year 0. Annual O&M costs occur in Years 1-30.

	Quantity	Unit	Unit Cost	Total Cost	
Operations				Odd Year	Even Year
Turnkey Services	1	LS	$ 1,305,700	$ 1,305,700	$ 1,305,700
Extra Electricity - Booster Pump Station	1	LS	$ 67,650	$ 67,650	$ 67,650
Electricity (Saugus 1 & 2 Pumps)	3,919,399.2	KW-HR	$ 0.10	$ 391,940	$ 391,940
Value of Reject Water	1	LS	$ 284,167	$ 284,167	$ 284,167
Disinfection Equipment	1	LS	$ 24,402	$ 24,402	$ 24,402
Reject (Brine) Disposal (not Included)	1	LS	$ -	$ -	$ -
Subtotal				$ 2,073,858	$ 2,073,858
Sentinel Monitoring Program					
Odd Year Sampling	22	EA	$ 488	$ 10,736	
Even Year Sampling	22	EA	$ 610		$ 13,420
Odd Year Analysis	22	EA	$ 525	$ 11,550	
Even Year Analysis	22	EA	$ 773		$ 17,006
Residuals Management	2	LS	$ 1,500	$ 3,000	$ 3,000
Subtotal				$ 25,286	$ 33,426
Subtotal				**$ 2,099,144**	**$ 2,107,284**
Contingency	20%			$ 419,829	$ 421,457
Subtotal				**$ 2,518,973**	**$ 2,528,741**
Technical Support and Report Preparation	15%			$ 377,846	$ 379,311
Total Annual O&M Costs for Alternative 4				**$2,896,819**	**$2,908,052**

Notes

1. Membrane filtration treatment system "Turnkey" O&M costs are estimated using cost curve for nanofiltration from 2004 AwwaRF final report on "Cost Implications of a Lower Arsenic MCL."
2. Extra electricity to boost RO permeate 80 psig to 100 psig delivery pressure.
3. Value of RO reject water has been included, as this is a lost asset.
4. O&M costs associated with RO reject disposal are not included, but could be substantial.

Table C-9: Alternative 3 Present Value Analysis

Alternative: Fluidized Bed Reactor
Site: Production Wells
Location: Santa Clarita Valley, CA
Phase: Planning (-30% to +50% accuracy)
Base Year: 2004

Description: Utilization of existing water distribution system with some modifications and additions, fluidized bed reactor treatment with 2,400 gpm capacity, discharge of treated water into existing 102-inch raw water pipeline, abandon Wells NC-11 & V-157. Capital costs occur in Year 0. Annual O&M costs occur in Years 1-30.

Appendix D

Proposed Confirmation Sampling Program – Perchlorate Containment and Treatment

Table D-4: Analytical Parameters for Sentinel Well Sampling[a]

Analytical Parameters	EPA Method	Sample Collection Frequency			
		Initial	Semiannual	Annual	Biannual
Volatile Organic Compounds[b]	524.2	X	X		
Perchlorate	314.0	X	X		
General Minerals					
Aluminum	6010	X			X
Bicarbonate/Alkalinity	310.1	X			X
Calcium	6010	X			X
Chloride	300	X			X
Total Phosphorus	365.3	X			X
Potassium	7610	X			X
Iron	6010	X			X
Magnesium	6010	X			X
Manganese	6010	X			X
Sodium	7770	X			X
Sulfate	300	X			
Nitrate	352.1	X		X	
Ammonia	350.3	X		X	X

(a) Sentinel well sampling program as developed in accordance with requirements of DHS Policy Memo 97-005, and presented in *Analysis of Perchlorate Containment in Groundwater Near the Whittaker-Bermite Property, Santa Clarita, California. Prepared for Upper Basin Water Purveyors in Support of the 97-005 Permit Application.* CH2MHILL 2004.

(b) Will include reporting of methyl tertiary butyl ether (MTBE) and 1,2,4-trimethyl benzene as well as any tentatively identified compounds.

Table D-3: Proposed Sentinel Well Groundwater Quality Monitoring[a]

Production Well	Location/Purpose	Actual or Target Screened Interval (feet bgs)[b]	Sentinel Well Name	Comments
Saugus 1				
	Magic Mountain Parkway east of Saugus 1	60-80	AL-12A	Monitor potential alluvium pathway to Saugus 1
	Magic Mountain Parkway east of Saugus 1	180-190	AL-12B	Monitor potential alluvium pathway to Saugus 1
	Magic Mountain Parkway east of Saugus 1	265-285 (HSU S-I)[c]	SG1-HSU1	Monitor HSU S-I
	Proposed – north of Saugus 1 near intersection of Magic Mountain and San Fernando	490-520 (HSU S-III)	SG1-HSU3a	Monitor HSU S-III
	Proposed – north of Saugus 1 near intersection of Magic Mountain and San Fernando	580-640 (HSU S-III)	SG1-HSU3b	Monitor HSU S-III
	Proposed – north of Saugus 1 near intersection of Magic Mountain and San Fernando	750-770 (HSU S-III)	SG1-HSU3c	Monitor HSU S-III
Saugus 2				
	Across San Fernando, east of Saugus 2	65-85	AL06	Monitor potential alluvium pathway to Saugus 2
	At Whittaker property line, southeast of Saugus 2	391.4-401.4 (HSU S-III)	MP-1 (port 2)	Monitor HSU S-III
	At Whittaker property line, southeast of Saugus 2	747.5-757.5 (HSU S-V)	MP-2 (port 4)	Monitor HSU S-V

(a) Sentinel well sampling program as developed in accordance with requirements of DHS Policy Memo 97-005, and presented in the *Analysis of Perchlorate Containment in Groundwater Near the Whittaker-Bermite Property, Santa Clarita, California. Prepared for Upper Basin Water Purveyors in Support of the 97-005 Permit Application.* CH2MHILL, 2004.

(b) Feet bgs = feet below ground surface.

(c) HSU = hydrostratigraphic unit as identified in the *Eastern Santa Clara Subbasin Groundwater Study, Santa Clarita, California, Conceptual Hydrogeology Technical Memorandum*. CH2MHILL, 2005. HSUs in Saugus Formation identified from shallowest to deepest as S-I to S-VII.

Table D-2: Proposed Compliance and Process Control Sampling – Perchlorate Treatment System

	Frequency		
Location	Daily	Weekly[a]	Quarterly[b]
Combined Influent	pH, turbidity, TDS[c], hardness, total alkalinity, chloride	Nitrate, sulfate, perchlorate	Iron, manganese, total organic carbon, dissolved organic carbon
Effluent from Lead Vessel	Chloride, perchlorate		
Effluent from Lag Vessel	TDS, chloride	Hardness, total alkalinity, perchlorate, nitrate, HPCs[d], total coliform	
Effluent from Equalization Tank	pH, turbidity, total chlorine, temperature	HPCs, total coliform	Iron, manganese

(a) Weekly sampling includes daily parameters, plus additional parameters listed.
(b) Quarterly monitoring event will be scheduled to coincide with a weekly event.
(c) TDS = total dissolved solids.
(d) HPC = heterotrophic plate count, a measure of heterotrophic bacteria.

Table D-1: Proposed Production Well Sampling Program

Frequency	Analytical Parameter	EPA Method	Purpose
Monthly	Coliform	SM9222B	DHS requirements[a]
	HPC[b]	SM9215B	DHS requirements
	Perchlorate	314.0	
Quarterly[c]	Hardness	200.7	DHS requirements, process control
	Total alkalinity	310.1	DHS requirements
	Chloride	300.0	DHS requirements
	Nitrate	352.1	DHS requirements, process control
	Sulfate	300.0	DHS requirements, process control
	pH	Field	DHS requirements, process control
	Iron	6010	DHS requirements
	Manganese	6010	DHS requirements
	Turbidity	180.1	DHS requirements
	Total Dissolved Solids	160.1	DHS requirements
	VOCs	524.2	DHS requirements and ongoing monitoring of OU7 groundwater quality
Annual	Title 22 and vulnerable constituents[d]	Various	DHS requirements and ongoing monitoring of OU7 groundwater quality

(a) DHS requirements applicable to operation of groundwater production wells for non-transient community water supply systems.
(b) HPC = heterotrophic plate count, a measure of heterotrophic bacteria.
(c) The quarterly monitoring event will be scheduled to coincide with a monthly event, and will include the parameters subject to monthly monitoring requirements.
(d) May include metals, explosive residuals, semivolatile organic compounds. Analytical suite may be modified in response to chemicals encountered in ongoing sampling of OU7 monitoring wells by Whittaker Corporation.

groundwater monitoring events to be performed by Whittaker. During the sentinel well monitoring events, field parameters including temperature, pH and conductivity will be measured using hand-held field instruments.

Samples will be analyzed for perchlorate and the standard water quality parameters at CLWA's analytical laboratory at the Rio Vista Water Treatment Plant. The CLWA analytical laboratory is certified by DHS for the analysis of these parameters.

In addition to parameters that will be evaluated through the collection and laboratory analysis of samples, other parameters will be monitored on an ongoing basis, with information transmitted electronically to operators at the Rio Vista Water Treatment Plant. These parameters include:

- Operational status of chemical feed pumps
- High water level in equalization tank
- Operational status of treated water pumps
- Operational status of production well pumps
- Pressure loss in containment piping
- Chlorine residual
- pH

CLWA's objective is to maintain residual chloramine at a concentration between 2.5 and 3.5 milligrams per liter (mg/l). Chloramine concentrations will be monitored using an in-line sampling and analysis process at the perchlorate treatment system. Confirmation samples will be collected as indicated in Table D-2.

In order to reduce accumulation of scale (hardness compounds) within the ion exchange vessels, an acidic solution will be injected into the groundwater upstream of the vessels. In-line analysis of pH will be performed to confirm the correct adjustment of pH.

D.3 Sampling of Sentinel Groundwater Monitoring Wells

Nine sentinel groundwater monitoring wells will be sampled on a semiannual basis to evaluate potential changes in chemical concentrations in groundwater that is approaching the Saugus 1 and Saugus 2 production wells. The locations of the sentinel wells were selected so that the sampling results can be used to provide "early warning" regarding potential increased concentrations of perchlorate or other site-related chemicals (such as volatile organic compounds (VOCs)) that may develop in groundwater within the capture zone of the production wells and that could potentially affect the proposed perchlorate treatment process. The sentinel wells are intentionally located a sufficient distance upgradient of the production wells to allow response time (such as construction of an additional treatment unit process) before chemical concentrations in the production wells exceed applicable drinking water standards.

Table D-3 summarizes the locations of the monitoring wells proposed for inclusion in the sentinel well monitoring program. At this time, six of the nine monitoring wells have been installed and three additional wells will be installed as part of the activities identified in the IRAP.

It is anticipated that the sentinel wells will be monitored on a semiannual basis, with samples submitted to a state-certified analytical laboratory for analysis of VOCs and perchlorate. Samples will be collected from the single-completion monitoring wells using standard well purging and sample techniques. Sampling of the individual ports on the multi-port wells requires specific equipment, but does not require purging. The proposed analytical parameters are listed in Table D-4. It is anticipated that the monitoring events for the sentinel wells will be coordinated with

Appendix D: Proposed Confirmation Sampling Program – Perchlorate Containment and Treatment System

Operation of the perchlorate containment and treatment program as described in this Interim Remedial Action Plan (IRAP) will include several forms of monitoring to evaluate the effectiveness of the containment pumping and perchlorate removal systems. The several components of the proposed monitoring and sampling program are summarized below.

Because the treated groundwater will be pumped into the community water distribution system, the proposed sampling program is also subject to the approval of the California Department of Health Services (DHS). As the proposed project is further developed during design, and/or in response to DHS requirements regarding community water supply systems, modifications to the proposed monitoring and sampling program may be identified. It is anticipated that a more detailed operation, maintenance and monitoring plan will be developed and implemented following completion of CLWA's 97-005 Engineer's Report and its approval by DHS. Personnel assigned the responsibility for collection of samples will be appropriately trained.

D.1 Sampling of Production Wells

During operation, wellhead samples will be collected from the Saugus 1 and Saugus 2 production wells in accordance with applicable DHS requirements. The proposed sampling frequency and analytical suite is set forth in Table D-1. The wellheads include sample taps to facilitate collection of water samples.

After the production wells have been operated for at least one year, and the operators and agencies have developed confidence in the stability in the chemical parameters of interest, CLWA may request a reduction in the sampling frequency and/or the number of analytical parameters.

The operational status of the well pumps will be remotely monitored on a continuous basis. A flow recorder will be installed and maintained at each of the two production wells to allow evaluation of the amount of groundwater extracted from each well.

D.2 Sampling at Perchlorate Treatment System

Monitoring and sampling will be performed at the perchlorate treatment system for the purposes of process control and to confirm the effectiveness of perchlorate removal and disinfection. The proposed treatment system sampling program is summarized in Table D-2. In-line sample taps will be included in the piping upstream of the lead vessel, between the lead and lag vessels and downstream of the lag vessel to allow collection of water samples.

When perchlorate concentrations in a sample collected downstream of the lead vessel reach or exceed 4 micrograms per liter (µg/l), the supplier of the resin will be contacted to replace the exhausted ion exchange resin in the lead vessel. Replacement of exhausted resin will include switching the piping valves so that the previous lag vessel is now in the lead position, and that the replacement resin is placed into the vessel now serving in the lag position.

Samples will be collected downstream of the lag vessel on a weekly basis to confirm that perchlorate concentrations are less than analytical reporting limits (2 µg/l).

SUBJECT: Filing of Notice of Determination in compliance with Section 21152 of the Public Resources Code.

State Clearinghouse Number (if submitted to State Clearinghouse): SCH# 2005081053
Project Title: Groundwater Containment, Treatment, and Restoration Project

Project Location: City of Santa Clarita and portions of unincorporated Los Angeles County [Need map]

Project Description (include county): Project consists of modified wells to intercept perchlorate-contaminated groundwater, use of new and existing pipelines to deliver perchlorate-contaminated water to a new treatment plant, several new production wells, and new pipelines associated to deliver treated water and water from new wells.

This is to advise that the Castaic Lake Water Agency (☒ Lead Agency or ☐ Responsible Agency) has approved the above described project on September 14, 2005 and has made the following determinations regarding the above described project:

1. The project [☐ will ☒ will not] have a significant effect on the environment.
2. A Mitigated Negative Declaration was prepared for this project pursuant to the provisions of CEQA.
3. Mitigation measures [☒ were ☐ were not] made a condition of the approval of the project.
4. A mitigation reporting or monitoring plan [☒ was ☐ was not] adopted for this project.
5. A statement of Overriding Considerations [☐ was ☒ was not] adopted for this project.
6. Findings [☒ were ☐ were not] made pursuant to the provisions of CEQA.

This is to certify that the Final Mitigated Negative Declaration and record of project approval, is available to the General Public at: Castaic Lake Water Agency, 27234 Bouquet Canyon Road, Santa Clarita, CA 91350 and the Custodian of the Agency Record is April Jacobs, Acting-Secretary to the Board of Directors

CERTIFICATE OF FEE EXEMPTION

De Minimis Impact Finding

Project Title/Date Certified/Location Name:

Title: Groundwater Containment, Treatment and Restoration Project

Date Certified: September 14, 2005

Location: City of Santa Clarita and portions of unincorporated Los Angeles County (see attached map)

Project Proponent: Castaic Lake Water Agency (CLWA)

Address of Project Proponent: 27234 Bouquet Canyon Road, Santa Clarita, CA 91350

Project Description: The proposed project's goals and objectives are as follows: Project consists of modified wells to intercept perchlorate-contaminated groundwater, use of new and existing pipelines to deliver perchlorate contaminated water to a new treatment plant, several new production wells, and new pipelines associated to deliv treated water and water from new wells.

Findings of Exemption: The Negative Declaration, which consists of the Project Description and Environme Analysis, was prepared pursuant to California Environmental Quality Act (CEQA) Guidelines §15164. It v concluded in the Negative Declaration, and previously prepared Initial Study, that the proposed project would h no direct or indirect effects on wildlife resources or the habitat upon which the wildlife depends. Further, secondary adverse impacts to plant and animal life were identified in the Initial Study that would result from proposed project. No comments were received on the previously prepared documents that refuted the conclusion insignificant impacts to biological resources.

Certification:

I hereby certify that the decision maker of the lead agency, has made the above findings of fact for this project a that based upon the Initial Study, the project will not individually or cumulatively have adverse effects on wildl resources, as defined in Section 711.2 of the Fish and Game Code.

RESOLUTION NO. 2429
ADOPTION OF MITIGATED NEGATIVE DECLARATION
CASTAIC LAKE WATER AGENCY
GROUNDWATER CONTAINMENT, TREATMENT
AND RESTORATION PROJECT

WHEREAS, the Castaic Lake Water Agency circulated for public comment a proposed Mitigated Negative Declaration and an Initial Study on its proposed Castaic Lake Water Agency Groundwater Containment, Treatment and Restoration Project ("Project") to prevent further downstream migration of perchlorates (containment), treat any water extracted as part of the containment process (containment), and recover lost local groundwater production (production restoration);

WHEREAS, the said Agency received written public comments during the comment period from August 9, 2005 to September 8, 2005 on the said proposed Project;

WHEREAS, the Agency scheduled a public hearing on the proposed project at its Board Room, 27234 Bouquet Canyon Road, Santa Clarita, CA 91350 for September 14, 2005 at 7:00 P.M. for purposes of considering the public comments as part of its decisional process concerning the proposed Project;

WHEREAS, pursuant to Public Resources Code section 21092.5 the public hearing did not constitute an extension of the public comment period, and no responses are required under said Public Resources Code section to comments made because the hearing was scheduled after the close of the public comment period;

WHEREAS, this Board has carefully and thoroughly reviewed the proposed Final Mitigated Negative Declaration and the Initial Study (Exhibit "A" to this Resolution), all public comment period comments pertaining thereto (Exhibit "B" to this Resolution), and the Mitigation and Monitoring Plan (Exhibit "C" to this Resolution), all of which documents are hereby attached as exhibits to this Resolution, and thereby incorporated herein by reference into this Resolution;

WHEREAS, as a result of public comment period comments and comments made at the public hearing on September 14, 2005, the Agency's Board has determined that the proposed Project can be approved because there is no substantial evidence in light of the whole record that the Project may have a significant effect on the environment; and

WHEREAS, the Agency and its Board have considered all of the information presented to it as set forth above and this Resolution and action taken hereby is a result of the Board's independent judgment and analysis.

NOW, THEREFORE, BE IT RESOLVED that this Board of Directors of the Castaic Lake Water Agency does hereby find and determine that the Final Mitigated Negative Declaration was prepared pursuant to the provisions of CEQA, that there is no substantial evidence in light of the whole record that the Project will have a significant effect or impact on the environment, that the Final Mitigated Negative Declaration reflects the Agency Board's independent judgment and analysis;

RESOLVED FURTHER that the Agency's Board does hereby adopt the Final Mitigated Negative Declaration attached as Exhibit "A" to this Resolution and does hereby approve the Project;

RESOLVED FURTHER that this Agency's Board does hereby adopt the attached findings (Exhibit "D" to this Resolution) which the Agency's Board finds are supported by substantial evidence in light of the whole record, does certify this Final Mitigated Negative Declaration to be accurate and complete, as well as legally sufficient pursuant to the provisions of CEQA, and does direct Agency staff to promptly file a Notice of Determination with respect to the Project;

RESOLVED FURTHER that the location of the Agency's record on this matter is at the Castaic Lake Water Agency, 27234 Bouquet Canyon Road, Santa Clarita, CA 91350 and the Custodian of the Agency Record is April Jacobs, Acting-Secretary to the Board of Directors;

RESOLVED FURTHER, that the Project's environmental review process identified numerous mitigation measures designed to prevent potentially significant impacts that might occur. These mitigation measures either have been incorporated into the Project or specified in the Initial Study, and will be monitored and enforced pursuant to the Mitigation and Monitoring Plan ("MMP"). The MMP includes the feasible mitigation measures for potentially significant direct Project impacts that are within CLWA's jurisdiction and authority to enforce. The MMP is required by Public Resources Code section 21081.6 and is attached to this Resolution as Exhibit "C" and is incorporated herein by this reference;

RESOLVED FURTHER, that the Agency's Board does hereby adopt the MMP; and

RESOLVED FURTHER, that the General Manager is authorized to execute all documents required to carry out and implement the Project as reviewed and approved by Agency's legal counsel, including, but not limited to, a Notice of Determination.

William Pecsi,
Board President

MITIGATION AND MONITORING PLAN

EXHIBIT "D"
FINDINGS

Finding No. One: Castaic Lake Water Agency ("Agency") has complied with all of the requirements for public notice under the Public Resources Code and the CEQA Guidelines.

Finding No. Two: The Agency has met all the requirements for public review under the Public Resources Code and CEQA Guidelines. Additionally, the Agency's Board has considered all received comments, both written and oral, including those comments submitted at the hearing on September 14, 2005. The comments, both written and oral, made at the public hearing do not raise any new information or issues that have not already been raised in the public comment period comments.

Finding No. Three: The proposed Final Mitigated Negative Declaration contains all the information required under the Public Resources Code and the CEQA Guidelines.

Finding No. Four: The Agency met all requirements for notice of the September 14, 2005 public hearing on the proposed Final Mitigated Negative Declaration.

Finding No. Five: The Initial Study meets the requirements of the Public Resources Code and the CEQA Guidelines, and the Agency followed all of the required procedures under the Public Resources Code and the CEQA Guidelines in preparing the Initial Study.

Finding No. Six: The Initial Study contains no evidence that the Project, with the mitigation specified, may have a significant effect upon the environment.

Finding No. Seven: The Agency is the proper lead agency for preparation of a mitigated negative declaration under the Public Resources Code and the CEQA Guidelines.

Finding No. Eight: Based upon the above it is found and determined that the Project will not have a significant effect and impact upon the environment, that the Public Resources Code and the CEQA Guidelines permit preparation of a Mitigated Negative Declaration for this Project, and that the Mitigated Negative Declaration reflects the Agency Board's independent judgment.

FINAL MITIGATED NEGATIVE DECLARATION

Project Name: Castaic Lake Water Agency, Groundwater Containment, Treatment, and Restoration Project

Project File Number: NA

Project Location: The project is located in the City of Santa Clarita and on lands west of the City of Santa Clarita and southwest of Magic Mountain Amusement Park.

County Supervisorial Districts: Fifth District (Michael Antonovich)

Mailing Address and Phone Number of Applicant Contact Person for this Project:

Mr. Ken Petersen,
Castaic Lake Water Agency
27234 Bouquet Canyon Road
Santa Clarita, CA 91350-2173
Phone 661-513-1260

Project Description:

The purpose of the proposed Castaic Lake Water Agency Groundwater Containment, Treatment, and Restoration Project (Proposed Project) is to prevent further perchlorate contamination of groundwater basins in the Santa Clarita Valley originating at an historic weapons manufacturing site located east of the South Fork of the Santa Clara River near the confluence of the South Fork and the Mainstem Santa Clara River. The Proposed Project will intercept the existing plume of perchlorate in the Saugus Formation groundwater and pump the contaminated water from intercepting wells to a new treatment plant, where perchlorate will be removed and the treated water utilized as part of Castaic Lake Water Agency's (CLWA) drinking water supply.

The Proposed Project would involve (a) modification of existing production wells, (b) construction and operation of new monitoring and production wells, (c) modification of existing pipelines and construction of new pipelines, (d) construction of a new, modular perchlorate water treatment plant, and (e) closing of existing production wells.

The Propose Project has two interrelated elements. First, there are facilities for the containment and treatment of perchlorate-contaminated groundwater. Second, there are service restoration facilities to replace and relocate existing facilities which must be closed or modified to accomplish the containment program objectives. With the exception of two pipeline segments under bridge decks, pipelines will be buried. The Proposed Project incorporates a number of conservation/impact minimization measures into its project description, including measures related to:

- Facility Siting
- Construction Schedule

- River Crossings
- Best Management Practices, Construction in Roads
- Best Management Practices, Construction in Bike Trails
- Aesthetic Treatment of the Treatment Facility
- Air quality
- Noise
- Biological Resources
- Water Quality
- Cultural Resources

As appropriate, these conservation/impact minimization procedures will be incorporated into construction contracts and performance will be independently verified by CLWA and/or qualified monitors. These elements of the project, described in full in the Initial Study, result in reduction of potential environmental impacts to a level of less-than-significant. In addition, CLWA proposes an additional site-specific monitoring and mitigation measure related to noise that may be implemented if on-site monitoring determines that minimization measures have not reduced noise levels to the desired levels.

Measures Included in the Project to Reduce Potentially Significant Effects to a Level of Less-Than-Significant (Described in detail in the Initial Study and incorporated by reference herein.)

Aesthetics: Facilities have been sited to avoid impact to scenic resources. Above ground facilities will be designed to be consistent with existing visual character of adjacent development.

Agricultural Resources: None. The Proposed Project will not affect agricultural resources.

Air Quality: The Proposed Project incorporates best management practices per Rule 403 of the South Coast Air Quality Management District, Table 1.

Biological Resources: The project has been sited to avoid direct impact to wildlife and wildlife habitat. Indirect effects associated with noise and visual disturbance are avoided/minimized by construction scheduling outside of nesting/breeding season for special-status birds in the adjacent Santa Clara River. The project includes construction crew training, on-site biological monitoring, and isolation of the construction area from any adjacent habitats during construction to prevent adverse impacts associated with wildlife incidental use of the construction area.

In response to comments received from the California Department of Fish and Game (CDFG) during the public comment period, CLWA hereby adopts additional mitigation measures related to biological resources. Specifically, CLWA will consider the breeding bird season to be March 1 through September 1 and as early as February 1 for raptors. Accordingly, to the extent feasible, CLWA will schedule construction activities along the south bank of Santa Clara River to avoid construction during the breeding season. In accordance with CDFG's comments, if construction cannot be scheduled to avoid the breeding bird season, CLWA will arrange for weekly bird surveys by a qualified biologist to detect any protected native birds in habitat within 300 feet of the construction work area (within 500 feet for raptors). Surveys should continue such that the last survey shall be conducted no more than 3 days prior to initiation of construction. If an active nest is located, construction within 300 feet (500 feet for raptors) shall be postponed until the nest is vacated and juveniles have fledged and when there is no evidence of a second attempt at nesting. Nest avoidance limits described above shall be identified in the field by flagging and stakes or construction fencing. Construction personnel will be instructed on the sensitivity of the avoidance area. Particular care shall be taken with regard to white-tailed kite nesting habitat upstream of the Bouquet Canyon Road crossing of the Santa Clara River.

In addition, CLWA will survey for bats under the Bouquet Canyon Bridge prior to construction. Per CDFG's request, CLWA will develop avoidance and mitigation measures if bats are found. If bats are located, impacts may be avoided by scheduling work during the non-nesting season (after September 1 and before March 1). Bats leaving the structure at night may then be excluded from returning to the bridge with fine mesh. CLWA will consult with CDFG during implementation of such impact avoidance measures.

Finally, CLWA will adopt additional measures to ensure that there are less-than-significant impacts associated with work in the river bed of the Santa Clara River during installation of the proposed pipeline under bridge decking:

a. All construction will be done in dry conditions;
b. Construction equipment will access the river bed via an area without native riparian vegetation;
c. Construction equipment fueling and maintenance will be performed outside of the riverbed or if necessary these activities will be performed using containment vessels;
d. Spills of fuel or other materials used during construction will be immediately reported and cleaned up in accordance with rules of the Regional Water Quality Control Board.

CLWA will confer with CDFG staff during processing of a Fish and Game Code Section 1600 permit (Streambed Alteration Permit) and implement other best management practices as required.

Cultural Resources: Project siting focuses on already heavily disturbed areas, reducing the potential for effects on cultural resources. Where buried cultural resources may occur, construction personnel training, construction monitoring and resource recovery, and compliance with California Department of Health Services requirements of treatment of buried human remains will reduce cultural resource impacts to a level of less-than-significant.

Geology and Soils: Mitigation measures to reduce erosion and drainage from construction sites are included, consistent with the requirements of the City of Santa Clarita Encroachment Permit Policy.

Hazards and Hazardous Materials: Materials associated with operation of the perchlorate treatment facility are stable and not considered hazardous. All water treatment materials will be transported, handled, and stored in accordance with current regulations, including use of secondary containment vessels.

Hydrology and Water Quality: The project includes best management practices for construction to avoid and minimize potential construction-related effects on drainage and water quality.

Land Use and Planning: None. The Proposed Project would have no effects on land use.

Mineral Resources: None. The Proposed Project would have no effects on mineral resources.

Noise: Project siting reduces potential construction and operation related noise impacts. The Proposed Project incorporates measures that will reduce potential noise from above ground facilities. The Proposed

Project includes noise monitoring and mitigation measures to reduce noise effects on residential housing adjacent to pipeline construction areas.

Population and Housing: None. The Proposed Project would have no effects on population and housing.

Public Services: None. The Proposed project has no effects on public service requirements or facilities.

Recreation: None. The Proposed Project will have only temporary and less-than-significant impacts on recreation facilities. Per comments from County of Los Angeles Department of Parks and Recreation, CLWA will coordinate any trail issues related to the South Fork Trail with the City of Santa Clarita.

Transportation and Traffic: Construction best management practices defined in the City of Santa Clarita Encroachment Permit will be implemented to minimize traffic effects associated with construction in and adjacent to roads. Per comments from the California Department of Transportation, CLWA will also require construction contractors to (a) avoid excessive or poorly timed truck platooning and (b) limit construction-related truck traffic on state highways to off-peak commute periods. CLWA recognizes that a Caltrans Encroachment Permit would be needed for construction in the State Right-of-Way but concurs with Caltrans that the project will not have an impact on State right of way.

Utilities and Service Systems: Pre-construction coordination will identify potential utilities which may be affected by the project and coordination with owners and construction best management practices will avoid impacts to utilities.

Cumulative Impacts: None. The Proposed Project has no significant cumulative impacts.

Mandatory Findings of Significance: None. The Proposed Project does not cause impacts that require a mandatory finding of significance

FINDINGS

1. CLWA has considered comments received during the public review period and has added specific impact avoidance and mitigation measures as recommended by CDFG, County of Los Angeles Department of Parks and Recreation, and California Department of Transportation. Copies of these comments are attached to this Mitigated Negative Declaration.

2. CLWA finds that the additional avoidance and minimization measures recommended by CDFG, County of Los Angeles Department of Parks and Recreation, and California Department of Transportation are consistent with the intent of the avoidance and minimization measures already incorporated into the project. CLWA finds that recirculation of the Mitigated Negative Declaration is not required because these more specific mitigation measures clarify and provide for more effective avoidance and mitigation measures consistent with Section 15074.1 of the CEQA Guidelines.

3. No other substantive comments, verbal or written, were received. There were no project revisions. No new information has been added to the Mitigated Negative Declaration.

4. CLWA has adopted a Mitigation Monitoring Plan for the project.

5. CLWA finds that the inclusion of the additional impact avoidance and mitigation measures requested by CDFG, County of Los Angeles Department of Parks and Recreation, and California Department of Transportation strengthens the finding that the Proposed Groundwater Containment, Treatment, and Restoration Project will have less-than-significant impacts on the environment.

Based on the above, the Board of Directors of the Castaic Lake Water Agency adopted this Mitigated Negative Declaration on September 14, 2005.

Mr. Ken Peterson
Castaic Lake Water Agency
27234 Bouquet Canyon Road
Santa Clarita, California 91350

Dear Mr. Peterson:

Thank you for including the California Department of Transportation in the environmental review process for the above-mentioned project. Based on the information received, we have the following comments:

It appears that the proposed project would not have an impact on the State Right-of-way. However, any work to be performed within the State Right-of-way will need a Caltrans Encroachment Permit. A Transportation Management Plan will be needed for any lane closures, detours, parking restrictions, etc.

We recommend that construction related truck trips on State highways be limited to off-peak commute periods. Transport of over-size or over-weight vehicles on State highways will need a Caltrans Transportation Permit.

The contractor should agree to avoid excessive or poorly timed truck platooning (caravans of trucks) to minimize transportation related operational conflicts, minimize air quality impacts, and maximize safety concerns.

If you have any questions regarding our comments, please refer to our IGR/CEQA Record number cs/050817 and do not hesitate to contact me at (213) 897-3747.

Sincerely,

Cheryl J. Powell

Draft Mitigated Negative Declaration for
Castaic Lake Water Agency
G oundwater Contaminant Treatment and Restoration Project
SCH # 2005081053, Los Angeles County

Dear Mr. Peterso

The Departm nt of Fish and Game (Department) has reviewed the Draft Mitigated Negative Declaration (MND and Initial Study (IS) for the above-referenced project. The project consists of modifying existing groundwater wells to intercept perchlorate-contaminated groundwater, use of new and existing pelines to deliver perchlorate-contaminated groundwater to a new modular treatment plant, ir talling several new production wells, and new pipelines to deliver treated water and water fi m new wells. New pipelines will be installed via trenching along established road and recreatic al bike path right-of-ways. Proposed pipeline crossings of the Santa Clara River (SCR) will b achieved by jacking beneath the riverbed. One SCR pipeline crossing will be accomplished by taching the pipeline beneath the Bouquet Canyon Road bridge deck. The project is loca d in the City of Santa Clarita near Interstate 5, Magic Mountain Parkway and Bouquet Canyon F oad.

These comm nts have been prepared pursuant to the Department's authority as Trustee Agency with jurisdi tion over natural resources affected by the project (CEQA Sectio 15386) and pursuant to ou authority as a Responsible Agency under the California Environmental Quality Act (CEQA Section 15381 regarding those aspects of the proposed project that come under the purview f the California Endangered Species Act (Fish and Game Code Section 2050 et esq.) and Fish a d Game Code Section 1600 et seq.:

IMPACTS TO SEN ITIVE BIOLOGICAL RESOURCES

1. <u>Native Nest g Birds</u> - The IS states that the project will be conducted along the Santa Clara River in Sep ember through Mid-March to avoid the nesting season.

   a. The Dep rtment concurs that the project may adversely impact native nesting birds. Th Department generally recognizes the breeding bird season to run from Ma ch 1- September 1 and as early as February 1 for raptors. This expande no-work period will help avoid take, including disturbances which would ca se abandonment of active nests containing eggs and/or young.

   b. The plac ment of the treatment water pipeline beneath the Bouquet Road Bridge deck ac oss the SCR should also take place outside of the nesting season as stated by tl : Department above to assist in avoiding nesting birds and bat nurseries/roosts.

c. The louquet Canyon Bridge should be surveyed for bats. If found, avoidance and iitigation measures should be developed.

d. If prc ect activities cannot avoid the breeding bird season, the Departrr ent reco mends that beginning thirty days prior to the disturbance of suitable nest g habitat the project proponent should arrange for weekly bird surveys to de ect any protected native birds in the habitat that is to be disturbed, and any c her such habitat within 300 feet of the construction work area (within 500 f et for raptors). The surveys should be conducted by a qualified biolo ist with experience in conducting breeding bird surveys. The surveys shou l continue on a weekly basis with the last survey being conducted no more han three days prior to the initiation of clearance/ construction work. If a pro acted native bird is found, the project proponent should delay all clear nce/ construction disturbance activities in suitable nesting habitat or withi 300 feet of nesting habitat (within 500 feet for raptor nesting habitat) until , ugust 31 or continue the surveys in order to locate any nests. If an activ nest is located, clearing and construction within 300 feet of the nest (withi 500 feet for raptor nests) shall be postponed until the nest is vacated and ju reniles have fledged and when there is no evidence of a second attem t at nesting.

The n st avoidance distance limits described above should be identified in the fie d with flagging and stakes or construction fencing. Construction perso nel should be instructed on the sensitivity of the avoidance area. The projec proponent should record the results of the recommended protective meas es described above, in order to document compliance with applicable State nd federal laws pertaining to the protection of native birds.

e. White ailed kite (WTK) a California Species of Special Concern and Fully Protected Speci ; nested upstream near the Bouquet Canyon Road crossing of the SCR during he 2005 nesting season. It is especially important that project activities do not tal : place near WTK active nest sites during the nesting season unless precor truction surveys for WTK along with other native bird species are conducted and av idance measures implemented as described above by the Department.

2. <u>Impacts to iparian Resources</u> – The IS states that the proposed pipeline will cross the SCR at the louquet Canyon Road Bridge under the bridge deck and that the use of constructio equipment will take place within the SCR where previous disturbances took place in 20(; from bridge improvement work activities. The IS further states that all other SCR crossi gs shall occur by jacking beneath the riverbed.

The Depart ent may require a Streambed Alteration Agreement (SAA) pursuant to Section 160 et seq. of the Fish and Game Code, with the applicant prior to any project related dire or indirect impact to the SCR and/or other Department jurisdictional drainages o associated riparian resources. The Department's issuance of a SAA may be a project the is subject to CEQA. To facilitate our issuance of the Agreement when CEQA appli ;, the Department as a responsible agency under CEQA may cor sider the local jurisdic on's (lead agency) document for the project. To minimize additional requirement by the Department under CEQA the document should fully identify the potential imp icts to the stream or riparian resources and provide adequate avoidance, mitigation, m nitoring and reporting commitments for issuance of the Agreement. Early consultat n is recommended, since modification of the proposed project may be required to avoid (reduce impacts to fish and wildlife resources. Please contact Ms. Betty Courtney 661) 263-8306 to discuss further.

The Depa tment recommends that the above concerns are addressed prior to lead agency approval f the proposed project.

Thank yo for this opportunity to provide comment. Questions regarding th s letter and further coordinati n on these issues should be directed to Mr. Scott Harris, Associate Wildlife Biologist, at (626 797-3170.

Sincerely,

Larry L. Eng, Ph.D.
Regional Manager

Ken Petersen, Project Manager
Castaic Lake Water Agency
27234 Bouquet Canyon Road
Santa Clarita, CA 91350

Dear Mr. Petersen:

NOTICE OF INTENT TO ADOPT A MITIGATED NEGATIVE DECLARATION FOR THE CASTAIC LAKE WATER AGENCY GROUNDWATER CONTAINMENT, TREATMENT, AND RESTORATION PROJECT

The Mitigated Negative Declaration (MND) for the Groundwater Containment, Treatment, and Restoration Project has been reviewed for potential impacts on the facilities of the County of Los Angeles-Parks and Recreation. The Castaic Lake Recreation Area, a recreational lake that is managed and operated by this Department, is in the northern portion of the project's study area. The project will not impact this facility or any other facilities under the jurisdiction of our Department.

The proposed project may impact the South Fork Trail. Please contact Mr. Joe Inch at (661) 286-4000, City of Santa Clarita, to coordinate any trail issues.

Thank you for including the County of Los Angeles-Parks and Recreation in the review of this environmental document. If I may be of further assistance, please feel free to contact me at (213) 351-5133.

Sincerely,

Bryan Moscardini
Park Project Coordinator

RE: **SCAG Clearinghouse No. I 20050523 Castaic Lake Agency, Groundwater Containment, Treatment, and Restoration Project**

Dear Mr. Petersen:

Thank you for submitting the **Castaic Lake Agency, Groundwater Containment, Treatment, and Restoration Project** for review and comment. As areawide clearinghouse for regionally significant projects, SCAG reviews the consistency of local plans, projects and programs with regional plans. This activity is based on SCAG's responsibilities as a regional planning organization pursuant to state and federal laws and regulations. Guidance provided by these reviews is intended to assist local agencies and project sponsors to take actions that contribute to the attainment of regional goals and policies.

We have reviewed the **Castaic Lake Agency, Groundwater Containment, Treatment, and Restoration Project**, and have determined that the proposed Project is not regionally significant per SCAG Intergovernmental Review (IGR) Criteria and California Environmental Quality Act (CEQA) Guidelines (Section 15206). Therefore, the proposed Project does not warrant comments at this time. Should there be a change in the scope of the proposed Project, we would appreciate the opportunity to review and comment at that time.

A description of the proposed Project was published in SCAG's **August 1-15, 2005** Intergovernmental Review Clearinghouse Report for public review and comment.

The project title and SCAG Clearinghouse number should be used in all correspondence with SCAG concerning this Project. Correspondence should be sent to the attention of the Clearinghouse Coordinator. If you have any questions, please contact me at (213) 236-1851. Thank you.

Sincerely,

BRIAN WALLACE
Associate Regional Planner

EXHIBIT "C"
MITIGATION AND MONITORING PLAN

(This Page Intentionally Blank)

Mitigation and Monitoring Plan
Castaic Lake Water Agency
Groundwater Containment, Treatment, and Restoration Project

This Mitigation and Monitoring Plan (MMP) specifies mitigation actions and monitoring and reporting requirements for the *Castaic Lake Water Agency Groundwater Containment, Treatment, and Restoration Project*, consistent with the project Initial Study and Final Mitigated Negative Declaration. For each action or class of actions identified in the above documents, this plan specifies the following:

The required action
The schedule
The party responsible for implementing the action
The required reports
The entity to receive reports

For ease of use, the MMP is presented in tabular format. Adoption of this Mitigation and Monitoring Plan constitutes a commitment by Castaic Lake Water Agency (CLWA) to comply with and fund the require mitigation and monitoring. At its discretion, CLWA will implement the MMP through construction contractors and other independent contractors, as noted. In all cases, CLWA's Project Manager and/or designated compliance staff will routinely audit contractor compliance with the requirements of the MMP.

In general, construction contractors will implement aspects of the MMP related to the acquisition and compliance with construction permits from the City of Santa Clarita, the County of Los Angeles, and the State of California. If it is determined that such plans are required, this may include preparation of construction plans such as the State of California Storm Water Pollution Prevention Plan. CLWA's primary role in these efforts will be to require these activities as part of the scope of work for each construction project and contract, to review plans and specifications, to periodically conduct compliance audits to ensure that contractors are acting in accordance with their plans, and to maintain records of all compliance activities and reports. CLWA may independently contract for specialized compliance monitoring, such as monitoring related to biological and cultural resources; these independent monitors will work with construction contractors to ensure compliance with mitigation and monitoring plan requirements. The MMP is thus organized to make the responsibilities of CLWA, design engineers, construction contractors, and independent contractors clear, and thus focuses on the actions required by each entity.

Table MMP-1. Mitigation and Monitoring Commitments Checklist (R = Review, C = Specify requirement in construction contract, A = Compliance Action, RP = Reporting Requirement, I = Inspect, M = Maintain during operation, NA = not applicable)

Impact Category	Mitigation Measure (See Initial Study for details)	Responsible Parties and Role			
		CLWA	Design Contractor	Construction Contractor	Independent Contractor
Aesthetics	Design and construct Treatment Plant to be consistent with Rio Vista Intake Pump Station	RC	A	AR	NA
	Landscape proposed treatment facility along the bike trail	RC	A	AR	NA
	Ensure Treatment Plant lights are directed away from bike trail	RC	A	AR	NA
	Contain wells in structures and landscape	RC	A	AR	NA
Air Quality	Comply with SCAQMD Rule 403	RI	NA	AR	NA
	Comply with SCAQMD Rule 1179 (b) (6)	RI	A	AR	NA
Biological Resources	Install automatic shut off valves in perchlorate pipeline to ensure pipeline shut down if pipeline is damaged during operation	RIM	A	AR	NA
	Schedule construction along south bank of Santa Clara River and Bouquet Canyon Road for September 1-February 1	RC	NA	AR	NA
	For construction outside of the September 1-February 1, survey weekly for raptor nests 30 days prior to initiation of construction.	RC	NA	NA	AR
	If nests are found within 300 feet of construction area (500 feet for raptors), suspend construction until nests are empty, young have fledged, and there is no evidence of new nesting activity	RC	NA	AR	AR
	Flag construction areas to clearly mark off-limits areas at 300-foot and 500-foot from active nests	RC	NA	AR	AR
	Survey for bats under the Bouquet Canyon Bridge. If bats are located, impacts may be avoided by scheduling work during the non-nesting season (after September 1 and before March 1). Bats leaving the structure at night may then be excluded from returning to the bridge with fine mesh. CLWA will consult with CDFG during implementation of such impact avoidance measures.	RC	NA	AR	AR
	Develop and conduct a CDFG and USFWS training program for workers along the south bank of the Santa Clara River and Bouquet Canyon Road; post species information at the site	RC	NA	AR	AR

	Following biological survey to confirm no special status species at the construction site, install fine-mesh drift fence along boundary between river and construction site along the south bank of the Santa Clara River and Bouquet Canyon Road	RC	NA	AR	AR
	For installation of pipelines at Bouquet Canyon Road bridge, comply with CDFG 1600 permit requirements. Specifically: a. All construction will be done in dry conditions; b. Construction equipment will access the river bed via an area without native riparian vegetation; c. Construction equipment fueling and maintenance will be performed outside of the riverbed or if necessary these activities will be performed using containment vessels; d. Spills of fuel or other materials used during construction will be immediately reported and cleaned up in accordance with rules of the Regional Water Quality Control Board.	RC	NA	AR	AR
	To the extent feasible, along Mainstem and South Fork of Santa Clara river, use landward right-of way for side casting of spoil and for construction laydown and vehicle fueling and maintenance to isolate these activities from the river.	RC	NA	AR	AR
Cultural Resources	Where there is potential to encounter buried cultural resources (roads and trails along the South Fork of the Santa Clara River): a. Prior to construction, train construction personnel regarding recognition of buried cultural remains and establish procedures to halt construction immediately and notify qualified archeologist. b. In areas near a known cultural resource site, a qualified archeologist shall monitor construction. If resources are found, initiate consultation with the State Historic Preservation Office. c. Comply with Department of Health Services requirements for treatment of buried human remains.	RC	NA	AR	AR
Geology and Soils	Install automatic shut off valves in perchlorate pipeline to ensure pipeline shut down if pipeline is damaged during operation	RIM	A	AR	NA
	On-going monitoring of Treatment Plant operation	A	NA	NA	NA
	Provide secondary containment vessels for hazardous treatment plant chemicals	AIM	A	AR	NA
Hazards and	Design, construct, and operate to provide for best management	AIM	A	AR	NA

Hazardous Materials	practices for handling of chemicals at chloramination facilities				
	Provide secondary containment vessels for hazardous treatment plant chemicals	AIM	A	AR	NA
	During construction, comply with City of Santa Clarita policies related to emergency response plans or evacuation plans	RC	NA	A	NA
	Comply with City of Santa Clarita Encroachment Policy and County of Los Angeles Code, Division 1, Title 16 (where appropriate) regarding trench backfill and covering	RC	NA	AR	NA
Hydrology and Groundwater Quality	Contain construction-site drainage and sediments: a. Daily pre-construction equipment inspections to detect and repair leaks b. Use of secondary containment for fueling and chemical storage areas c. Use of secondary containment for equipment wash water d. Use of silt traps or basins to control runoff e. Cover stockpiles to prevent runoff f. Protect loose soils areas from potentially erosive runoff g. For construction in the river channel, equipment shall be fitted with secondary containment materials at potential oil/fuel leakage sites.	RCI	NA	AR	NA
	Prepare a *Storm Water Pollution Prevention Plan* if required	RC	NA	AR	NA
Noise	For construction adjacent to housing, comply with City of Santa Clarita Noise ordinances: a. Permanent above-ground facilities (wells and treatment plant) will be contained in structures to ensure adjacent noise levels are below levels established for facilities in commercial and manufacturing areas; b. Limit construction to the period 7 am to 7 pm; c. Monitor noise levels adjacent to housing and if levels at adjacent housing exceed City Noise Ordinance permitted levels (65 dBA), install temporary noise attenuation barriers	RC	A	AR	NA
Recreation	No more than one segment of bike trail will be affected at any time	RC	NA	AR	NA
	Detours around the construction zone will be as short as possible and temporary. As part of this action, post and maintain	RC	NA	AR	NA

	signage related to trail closures and detours.				
Transportation and Traffic	Comply with City of Santa Clarita Encroachment Permit Policy and/or County of Los Angeles Public Works Encroachment Permit requirements, County Code Division 1, Title 16 As feasible, limit construction related truck trips on state highways to off-peak commute periods. Obtain Caltrans Transportation Permit for transport of oversized or over-weight vehicles on State highways. Avoid excessive or poorly timed truck platooning.	RC	NA	AR	NA

Table MMP-2. Mitigation and Monitoring Responsibilities

1. CLWA Responsibilities (CLWA Compliance Manager amd/or Project Manager)			
Action	**Schedule**	**Required Reports**	**Report provided to:**
Assign a staff person (compliance manager) to oversee compliance with the commitments of the Initial Study and Mitigated Negative Declaration.	Prior to issuing construction contracts	None	None
Incorporate monitoring requirements in construction contracts and scopes of work	Prior to issuing contracting documents	Memo Record of Review	PM
Review Designs and Specifications to ensure that mitigation commitments related to design and construction are met	Prior to approving designs and specifications	Memo Record of Review	PM
Review project schedule to ensure that mitigation commitments related to scheduling are met	Prior to approving schedule	Memo Record of Review	PM
Periodic inspection of contractor compliance records	On-going	Memo Record of Review	PM
Contracting for independent mitigation and monitoring services for biological monitoring and management for construction along the south bank of the Santa Clara River and at bridge crossings along Bouquet Canyon Road	Schedule to ensure that services will be available at least 30 days prior to initiation of construction in these alignments	Memo Record of Review Approved contract	PM
Contracting for independent mitigation and monitoring services for cultural resources monitoring and management for construction activities involving work where excavations may extend to previously undisturbed soils and to coordinate with permitting agencies and the State Historic Preservation office during pre-construction planning	Initiated upon CLWA Board adoption of MND or approval of the proposed project	Memo Record of Review Approved contract	PM
Periodic inspection of construction sites during construction to confirm contractor compliance with construction monitoring and mitigation requirements	During construction mobilization, activity, and demobilization	Inspection Report/Checklist	PM
On-going coordination with permitting agencies prior to, during, and following construction; resolution of construction-related issues	During construction mobilization, activity, and demobilization	Inspection Report/Checklist	PM
Resolution of issues raised by permitting agencies and/or the public related to contractor mitigation and monitoring activities	On-going following CLWA Board adoption of the mitigated negative declaration and approval of the project	Memo Report of issues and their resolution	PM
Maintain a file of mitigation and monitoring compliance documents	During design, construction, mobilization, demobilization, and	NA	PM

	initial start-up and inspection of facilities		
Apply for CDFG Section 1600 Permit for work in the Santa Clara River (installation of pipelines under bridge decks). Incorporate required monitoring and mitigation requirements into construction contracts.	Prior to issuance of construction contracts	Memo Report certifying that construction contracts include 1600 permit requirements	PM
Inspect, operate and maintain all facilities to minimize the potential for facility damage and associated release of water from pipelines and chemicals used in facility operations.	On-going	NA	NA
2. Design Engineers			
Action	**Schedule**	**Required Reports**	**Report provided to:**
Review Department of Health Services permit requirements for the treatment plant and ensure compliance with these requirements	During Design	Memo certifying compliance with approved plans and specifications	Compliance Manager and PM
Design facilities in accordance with (as appropriate) a. DHS requirements b. Standard Specifications for Public works Construction	During Design	Memo certifying compliance with approved plans and specifications	Compliance Manager and PM
Design above-ground facilities to be consistent with surrounding buildings per aesthetics commitments	During design	Memo certifying compliance with approved plans and specifications	Compliance Manager and PM
Design pipelines and treatment facilities to provide for pipeline automatic shutoff valves and hazardous materials containment	During design	Memo certifying compliance with approved plans and specifications	Compliance Manager and PM
3. Construction Contractors and Independent Monitoring Contractors (Biological and Cultural)			
Action	**Schedule**	**Required Reports**	**Report provided to:**
As needed, obtain permit applications and file permit requests with City of Santa Clarita for Encroachment Permit and/or County of Los Angeles Public works Encroachment Permit (including, as needed, development and processing of a State *Storm Water Pollution Prevention Plan*)	30 days prior to construction in the public right of way	Copy of Encroachment Permit Application	CLWA PM
Develop appropriate compliance and reporting procedures for all work for which action is specified on Table MMP-1.	Prior to initiation of construction	Copy of compliance and reporting procedures, with City/County approval as needed	CLWA PM
Comply with encroachment permits, including but not limited to:	On-going during mobilization,	Copies of insurance certificates,	CLWA PM

a. Notification of start of work b. Contact of Underground Service Alert c. 24-hour prior notification of persons within 300 feet of work d. Utility repair e. Caltrans MUTCD California Supplement f. Lane closure hours g. Reports of damage to traffic control equipment h. Trench/hole closure when work is not in progress i. Testing and certification of trench compaction j. Testing and certification of paving k. Removal of Underground Service Alert markings l. Compliance with utility cover requirements m. Use of non-skid steel plates to cover open trenches n. Use of recessed steel plating if required o. Night work plan approved by City as needed p. Backfill requirements met q. Concrete/asphalt removal requirements met r. Sidewalk removal and replacement requirements met s. Heavy equipment transportation requirements met	construction, and demobilization (Daily, weekly, monthly as specified in encroachment permits)	compliance reports, checklists, City/County inspection reports, correspondence with City and County, and other required reports or documentation	
Comply with SCAQMD Rule 403, including but not limited to: a. Designation of a dust control supervisor per Rule 403 b. Table 1: Best Available Control Measures	On-going during mobilization, construction, and demobilization (Daily, weekly, monthly as specified in encroachment permits)	Copies of insurance certificates, compliance reports, checklists, City/County inspection reports, correspondence with City and County, and other required reports or documentation	CLWA PM
Comply with biological resources mitigation measures per Table MMP-1. For work along the south bank of the Santa Clara River and Bouquet Canyon Road, the biological monitor shall periodically inspect construction and shall have the authority to stop construction if necessary to ensure compliance with biological resources mitigation measures.	On-going during mobilization, construction, and demobilization (Daily, weekly, monthly as specified in encroachment permits)	Copies of, compliance reports, checklists, results of field surveys prior to and during nesting season, correspondence with CDFG and USFWS, copies of construction training materials, and other required reports or documentation	CLWA PM
Comply with cultural resources mitigation measures per Table MMP-1.	On-going during mobilization, construction, and demobilization (Daily, weekly, monthly as specified in encroachment permits)	Copies of, compliance reports, checklists; correspondence with SHPO, DHS, and the Native American Heritage Commission,	CLWA PM

		as needed; copies of construction training materials; and other required reports or documentation	
Comply with plans and specifications with regard to all features related to leak prevention, and containment of hazards and hazardous materials.	On-going during mobilization, construction, and demobilization (Daily, weekly, monthly as specified in the noise ordinance)	Copies of insurance certificates, compliance reports, checklists, inspections, City inspection reports, correspondence with City, and other required reports or documentation	CLWA PM
Implementation of Best Management Practices for stormwater runoff control to contain runoff and sediment from construction. Preparation of a State *Storm Water Pollution Prevention Plan* if required. Specifically: a. Daily pre-construction equipment inspections to detect and repair leaks b. Use of secondary containment for fueling and chemical storage areas c. Use of secondary containment for equipment wash water d. Use of silt traps or basins to control runoff e. Cover stockpiles to prevent runoff f. Protect loose soils areas from potentially erosive runoff g. For construction in the river channel, equipment shall be fitted with secondary containment materials at potential oil/fuel leakage sites.	On-going during mobilization, construction, and demobilization (Daily, weekly, monthly as specified in the noise ordinance)	Copies of construction runoff control plan (a formal State *Storm Water Pollution Prevention Plan* as required), compliance reports, checklists, inspections, City inspection reports, correspondence with City, and other required reports or documentation	CLWA PM
Compliance with City of Santa Clarita Noise ordinances	On-going during mobilization, construction, and demobilization (Daily, weekly, monthly as specified in the noise ordinance)	Copies of insurance certificates, compliance reports, checklists, City inspection reports, correspondence with City, and other required reports or documentation	CLWA PM
Comply with MMP requirements for minimizing impacts to trails, including: a. Completion of construction and restoration of each segment of bike trail prior to initiation of construction of other segments b. Provide the shortest feasible detours around construction	On-going during mobilization, construction, and demobilization (Daily, weekly, monthly as specified in the noise ordinance)	Maps showing trail segments and proposed detours, schedule for construction,	CLWA PM

c. Post and maintain signs for trail closures and bike traffic detours d. Coordinate with City of Santa Clarita on bike trail closings and detours

CONNY B. McCORMACK, COUNTY CLERK
H. HARPER DEPUTY

Draft
MITIGATED NEGATIVE DECLARATION

Project Name: Castaic Lake Water Agency, Groundwater Containment, Treatment, and Restoration Project

Project File Number: NA

Project Location: The project is located in the City of Santa Clarita and on lands west of the City of Santa Clarita and southwest of Magic Mountain Amusement Park.

County Supervisorial Districts: Fifth District (Michael Antonovich)

Mailing Address and Phone Number of Applicant Contact Person for this Project:

Mr. Ken Petersen,
Castaic Lake Water Agency
27234 Bouquet Canyon Road
Santa Clarita, CA 91350-2173
Phone 661-513-1260

Project Description:

The purpose of the proposed Castaic Lake Water Agency Groundwater Containment, Treatment, and Restoration Project (Proposed Project) is to prevent further perchlorate contamination of groundwater basins in the Santa Clarita Valley originating at an historic weapons manufacturing site located east of the South Fork of the Santa Clara River near the confluence of the South Fork and the Mainstem Santa Clara River. The Proposed Project will intercept the existing plume of perchlorate in the Saugus Formation groundwater and pump the contaminated water from intercepting wells to a new treatment plant, where perchlorate will be removed and the treated water utilized as part of Castaic Lake Water Agency's (CLWA) drinking water supply.

The Proposed Project would involve (a) modification of existing production wells, (b) construction and operation of new monitoring and production wells, (c) modification of existing pipelines and construction of new pipelines, (d) construction of a new, modular perchlorate water treatment plant, and (e) closing of existing production wells.

The Propose Project has two interrelated elements. First, there are facilities for the containment and treatment of perchlorate-contaminated groundwater. Second, there are service restoration facilities to replace and relocate existing facilities which must be closed or modified to accomplish the containment program objectives. With the exception of two pipeline segments under bridge decks, pipelines will be buried. The Proposed Project incorporates a number of conservation/impact minimization measures into its project description, including measures related to:

- Facility Siting
- Construction Schedule
- River Crossings

THIS NOTICE WAS POSTED
ON SEP 2 0 2005
UNTIL OCT 2 0 2005
REGISTRAR-RECORDER/COUNTY CLERK

05-0016920

- Best Management Practices, Construction in Roads
- Best Management Practices, Construction in Bike Trails
- Aesthetic Treatment of the Treatment Facility
- Air quality
- Noise
- Biological Resources
- Water Quality
- Cultural Resources

As appropriate, these conservation/impact minimization procedures will be incorporated into construction contracts and performance will be independently verified by CLWA and/or qualified monitors. These elements of the project, described in full in the attached Initial Study, result in reduction of potential environmental impacts to a level of less-than-significant. In addition, CLWA proposes an additional site-specific monitoring and mitigation measure related to noise that may be implemented if on-site monitoring determines that minimization measures have not reduced noise levels to the desired levels.

The Proposed Project is described in greater detail in the attached Initial Study.

Measures Included in the Project to Reduce Potentially Significant Effects to a Level of Less-Than-Significant (See Initial Study for more detail on the measures outlined below.)

Aesthetics: Facilities have been sited to avoid impact to scenic resources. Above ground facilities will be designed to be consistent with existing visual character of adjacent development.

Agricultural Resources: None. The Proposed Project will not affect agricultural resources.

Air Quality: The Proposed Project incorporates best management practices per Rule 403 of the South Coast Air Quality Management District, Table 1.

Biological Resources: The project has been sited to avoid direct impact to wildlife and wildlife habitat. Indirect effects associated with noise and visual disturbance are avoided/minimized by construction scheduling outside of nesting/breeding season for special-status birds in the adjacent Santa Clara River. The project includes construction crew training, on-site biological monitoring, and isolation of the construction area from any adjacent habitats during construction to prevent adverse impacts associated with wildlife incidental use of the construction area.

Cultural Resources: Project siting focuses on already heavily disturbed areas, reducing the potential for effects on cultural resources. Where buried cultural resources may occur, construction personnel training, construction monitoring and resource recovery, and compliance with California Department of Health Services requirements of treatment of buried human remains will reduce cultural resource impacts to a level of less-than-significant.

Geology and Soils: Mitigation measures to reduce erosion and drainage from construction sites are included, consistent with the requirements of the City of Santa Clarita Encroachment Permit Policy.

Hazards and Hazardous Materials: Materials associated with operation of the perchlorate treatment facility are stable and not considered hazardous. All water treatment materials will be transported, handled, and stored in accordance with current regulations, including use of secondary containment vessels.

Hydrology and Water Quality: The project includes best management practices for construction to avoid and minimize potential construction-related effects on drainage and water quality.

Land Use and Planning: None. The Proposed Project would have no effects on land use.

Mineral Resources: None. The Proposed Project would have no effects on mineral resources.

Noise: Project siting reduces potential construction and operation related noise impacts. The Proposed Project incorporates measures that will reduce potential noise from above ground facilities. The Proposed Project includes noise monitoring and mitigation measures to reduce noise effects on residential housing adjacent to pipeline construction areas.

Population and Housing: None. The Proposed Project would have no effects on population and housing.

Public Services: None. The Proposed project has no effects on public service requirements or facilities.

Recreation: None. The Proposed Project will have only temporary and less-than-significant impacts on recreation facilities.

Transportation and Traffic: Construction best management practices defined in the City of Santa Clarita Encroachment Permit will be implemented to minimize traffic effects associated with construction in and adjacent to roads.

Utilities and Service Systems: Pre-construction coordination will identify potential utilities which may be affected by the project and coordination with owners and construction best management practices will avoid impacts to utilities.

Cumulative Impacts: None. The Proposed Project has no significant cumulative impacts.

Mandatory Findings of Significance: None. The Proposed Project does not cause impacts that require a mandatory finding of significance

FINDINGS

With the implementation of the mitigation measures outlined above and detailed in the attached Initial Study, the Proposed Groundwater Containment, Treatment, and Restoration Project will have less-than-significant impacts on the environment.

PUBLIC REVIEW PERIOD

Before 5:00 PM on September 8, 2005, any person may:

(1) Review the Draft Mitigated Negative Declaration (MND)

05 0016920

(2) Submit written comments regarding the information, analysis, and mitigation measures in the Draft MND. Before the MND is adopted, CLWA staff will prepare written responses to any comments, and revise the Draft MND, if necessary, to reflect any concerns raised during the public review period. All written comments will be included as part of the Final MND, and/or

(3) File a formal written protest of the determination that the project would not have a significant effect on the environment. This formal protest must be filed at the Castaic Lake Water Agency, 27234 Bouquet Canyon Road, Santa Clarita, CA 91350-2173, Attention: Mr. Ken Peterson. The written protest should make "fair argument" based on substantial evidence that the project will have one or more significant effects on the environment. If a valid written protest is filed with the Board of Directors of the Castaic Lake Water Agency within the noticed review period, the Board of Directors may (1) adopt the MND and set a noticed public hearing on the protest before the Board of Directors, (2) require the preparation of an environmental impact report and refund the filing fee to the person who filed the protest, or (3) require the draft MND to be revised and undergo additional noticed public review, and refund the filing fee to the person who filed the protest.

PUBLIC NOTICE
INTENT TO ADOPT A MITIGATED NEGATIVE DECLARATION
Castaic Lake Water Agency, Santa Clarita, CA

Project Title, Description, and Location: Groundwater Containment, Treatment, and Restoration Project

Castaic Lake Water Agency proposes a two-component Groundwater Containment, Treatment, and Restoration Project. The first component will involve construction and use of existing facilities to intercept perchlorate contaminated groundwater, convey this water to a new treatment plant for treatment, and put the resulting clean water to beneficial use. The second component will involve construction and use of existing facilities to restore historic production from several wells that will be permanently closed due to contamination by perchlorate. Facilities will involve a new treatment plant, pipelines constructed in road and bike-trail rights-of-way, modifications to existing wells and pipelines, and new wells. If the Proposed Project is implemented, construction of underground pipelines and other facilities will occur in the following locations:

1. On the west side of San Fernando Road south of Magic Mountain Parkway
2. Parallel to Magic Mountain Parkway from San Fernando Road to Valencia Boulevard
3. Parallel to Valencia Boulevard/Soledad Canyon Road from Magic Mountain Parkway to the bridge at Bouquet Canyon Road
4. Across the Santa Clara River along Bouquet Canyon Bridge
5. Within the levee/bike trail west of Bouquet Canyon Bridge to The Rio Vista Intake Pump Station
6. Within the trail corridor west of the South Fork of the Santa Clara River
7. Within the bike trail along the south levee of the Santa Clara River from the Valencia Boulevard bridge to McBean Parkway
8. At Castaic Lake Water District's existing facilities at Furnivall Avenue
9. Parallel to Magic Mountain Parkway from Interstate 5 west to an unpaved road west of Magic Mountain Amusement Park
10. Along the unpaved road west of Magic Mountain Amusement Park

California State Law requires Castaic Lake Water Agency to conduct environmental review to determine if a project may have a potentially significant effect on the environment. Environmental review examines the nature and extent of any potentially significant adverse impacts on the environment that could occur if a project is approved and implemented. The Board of Directors of the Castaic Lake Water Agency would require the preparation of an Environmental Impact Report if the review concluded that the proposed project could have significant unavoidable effects on the environment. The California Environmental Quality Act (CEQA) requires this notice to disclose whether any listed toxic sites are present; there are no listed toxic sites within the proposed construction areas.

Based on initial study, the General Manager has concluded that the project, which incorporates a number of impact avoidance, minimization, and mitigation measures, will not have significant adverse effects on the environment. The project has been formulated to avoid such impacts where there was a potential for them to occur. Castaic Lake Water Agency has sent this intent to adopt a Mitigated Negative Declaration for the proposed project to the State Clearinghouse, responsible agencies, trustee agencies, and the County Clerks of Los Angeles and Ventura to inform them of a public hearing on the project that will be on September 14, 2005 at the administration building of Castaic Lake Water Agency, 27234 Bouquet Canyon Road, Santa Clarita, CA 91350 at 5:00 PM. The draft Mitigated Negative Declaration, initial study, and the referenced technical documents are available for review under the above file number from 9:00 a.m. to 4:30 p.m., Monday through Friday at Castaic Lake Water Agency, 27234 Bouquet Canyon Road, Santa Clarita, CA 91350. The public review period for the Mitigated Negative Declaration is from August 9, 2005 through September 8, 2005. Written comments on the Proposed Project must be received by Castaic Lake Water Agency, 27234 Bouquet Canyon Road, Santa Clarita, CA 91350, ATTN: Mr. Ken Petersen, Project Manager on or before 5:00 PM, September 8, 2005.

05 0016920

Adoption of a Mitigated Negative Declaration does not constitute approval of the proposed project. The decision to approve or deny the project described will be made separately. For additional information or to obtain a copy of the draft Mitigated Negative Declaration, please call Ken Petersen, Project Manager, at 661-513-1260.

PUBLIC MEETING)
INTERIM REMEDIAL ACTION PLAN)
SEPTEMBER 7, 2005)

Public Meeting of Interim Remedial Action Plan taken at Santa Clarita City Hall, 23920 Valencia Boulevard, Santa Clarita, California, commencing at 6:38 p.m., Wednesday, September 7, 2005, before Laurie A. Schmidt, Certified Shorthand Reporter No. 12719.

SANTA CLARITA, CALIFORNIA

WEDNESDAY, SEPTEMBER 7, 2005

6:38 P.M.

YVETTE LADUKE: Good evening. Let's go ahead and get started. We want to thank all of you for coming out tonight to the meeting. Just in case any of you did not get a chance to sign in, our sign-in sheet is here as well as some copies of our presentation. So if you didn't get a chance to pick one of those up and would like one, please grab one.

And also up here we have speaker cards. They look like this here. And we ask that if you would like to ask any questions, please fill out one of these speaker cards.

And also we would like to ask that you please hold your questions until the end of the presentation. After we have completed the full presentation we will have a question and answer session then.

Also we would like to let everyone know up front that there is a court reporter present tonight so when we do get to the question and answer session if we could please have you -- we have a portable mike here that we will pass around. If you could each speak one at a time and into the microphone so that she can hear any of your questions.

I would like to introduce our panel to you tonight.

The first is Sara Amir. She's the Chief of Southern California Cleanup Operations, the Site Mitigation and Brownfields Reuse Program for the Department of Toxic Substances Control. And we have Ken Petersen who is the Project Manager for the Castaic Lake Water Agency. And over there at the computer is Jose Diaz. He's the Project Manager for Toxic Substances Control. And we have Mr. John McGinnis (phonetic) here who is a geologist with our department. And Rita Kumats (phonetic) who is the Unit Chief. And then I'm Yvette LaDuke, and I'm the Public Participation Specialist for DTSC.

And so tonight we are going to give you a presentation. First Sara Amir will start out and give you some background on our department.

SARA AMIR: Good evening everyone. Thank you for being here.

What I want to do tonight is just go over very briefly about who we are, and why we are here, and what is the role of our department. And then after that, Ken Petersen will talk about this project and explain what this project is all about. And then later on Yvette LaDuke will talk about the public participations process. And at the end we will open it up to questions and answers.

If we cannot answer your questions, we will get it in writing. Make sure that we have it. That's why we have the court reporter here. And we will respond in writing.

With that, DTSC, Department of Toxic Substances Control is a department within the California EPA, like Water Board, Waste Board, Air Resources Board, and OHHA of Office of Health Hazard Assessment Department. The DTSC is charged with protecting public health and the environment from harmful chemicals and hazardous substances or waste.

We are responsible for regulating hazardous waste generation, transportation, treatment, storage, and disposal in California.

We have many different staff, multi-disciplinary staff that helps in like a team, and work on a project. For example, on the Whittaker-Bermite project or this project there has been a specific project, we have geologists, scientists, engineers, toxicologists, public participation, and other staff who work as a team together to make sure that we answer all the questions. Whatever decisions we make, it's sound engineering and scientist decision. And it's protective of public health and the environment.

DTSC Site Mitigation Program is responsible for overseeing cleanup activities at a site to address the public health and environmental protection. We identify, assess, and carry over. And we oversee the clean up of sites. And also sometimes there are sites that we actually conduct a clean up.

On this particular site we have a responsible party who is doing the investigation and also remedial activities. And we oversee those remedial activities.

We have several programs within the Site Mitigation Program that facilitate the assessment and clean up of these contaminated properties.

Under California Health and Safety Code, Section 25355.5(a)(1)(C), we created a voluntary cleanup program. And on this site we entered into a voluntary cleanup agreement with Castaic Lake Water Agency in order to conduct an investigation and cleanup activities.

And as I said, we will oversee the implementation of the water suppliers groundwater containment project.

This is the overview of the site mitigation process. When a site comes under DTSC's oversight, we first do a Preliminary Endangerment Assessment or (PEA). Under a (PEA) we determine if there has been a release of hazardous substances. If there is no release then we issue a no further action, but if there are releases, then we go to the next step which is Remedial Investigation Health Risk Assessment and Feasibility Study.

After we complete this portion of the process then we go through the Remedial Action Plan. And tonight that's why we are here. We have a Remedial Action Plan which is up for public comments and review. And we have a 30-day public comment period. And tonight's meeting is in order to get your comments and respond to your questions.

The next step would be the remedial design and then implementation. After that, certification then operation and maintenance. On some sites the remedial action has to go on for years. For example, when we have water treatment, the remedial action has to go on for a long time. And that's why we have operation and maintenance, making sure that everything is in place and when yearly, or quarterly, or semi-annual we do the monitoring and make sure that what we have done for the treatment is actually doing its work and operating properly. And we make sure that the contamination is being reduced and is being cleaned up. And the plume, for example, for groundwater is being reduced.

Under the Voluntary Cleanup Program we have an agreement with the Castaic Lake Water Agency. And under the Scope of Work with that Voluntary Cleanup Agreement we have done Remedial Investigation and Feasibility Studies, and Remedial Action Plan. And as I said, tonight we are here to review that. And again, under that VCA there will be a remedial design and implementation. The implementation will include construction of a perchlorate treatment system and also construction of a dedicated underground piping. And we oversee all those.

With that, Ken Petersen from Castaic Lake Water Agency. Ken Petersen, who is the Project Manager, will talk about the project in depth.
Thank you very much.

KEN PETERSEN: Thank you, Sara.

My presentation tonight is to give you a little bit of a review of the project history, the development of alternatives, and of course the proposed projects. And the questions and answers I'm sure will clarify everything that I will say tonight.

Useful Terminology: Of course, Sara kind of gave you an overview of that already, what DTSC is, and what CERCLA is. And CERCLA is what we are trying to comply with, the Comprehensive Environmental Response, Compensation, and Liability Act. CERCLA provides an opportunity for us to recover costs as agencies from the cause of the contamination, et cetera. And, of course, we have talked about the Health and Safety Code. And the (RI), (FS) and (IRAP) is explained again there.

And of course, we are working today on an Interim Remedial Action Plan, therefore (IRAP) for those who like -- now this is a site plan of the area of concern. The Whittaker site is down here. The pump stations, the well pumps that have been affected by the perchlorate are shut down as Saugus-1 and Saugus-2 right here, Valencia V-157 is here, NC-11 down here, and a few years back Stadium Well here, and then of course Well Q-2 just recently.

This is the Rio Vista Intake Pump Station located in the Lowe's parking lot. It looks like a church. If you have seen it in the parking lot, you know what that is. And of course, the Rio Vista Treatment Plant which I will be talking about is located in the Central Park area. It's actually on top of the hill where the agency's offices are.

A little bit about the project history: In 1997 Perchlorate was detected in the Saugus wells and removed. And of course, they were removed from service immediately. DHS was involved with those findings, making this -- it was a contaminant concern, and we started testing for it at that time. In 2002 Stadium Well was removed from service when it was discovered. And then in 2003 we entered the Voluntary Agreement with DTSC.

Even though the Voluntary Agreement with Castaic Lake Water Agency and DTSC, the purveyors that have been affected by this was very much part of that. Just as Castaic Lake Water Agency became the overall agency that coordinated with DTSC to deal with this clean up.

Well Q2, too, was removed from service earlier this year from the heavy rains and also alluvium by the way. As far as from 2002 to 2005 recently and still working on some of the monies left over, purveyors obtained assistance from the United States Corps of Engineers for studies of the site which have been going on continually since then.

In 2005 the United States Corps of Engineers produced a Technical Memorandum which provided really the basis of our Feasibility Analysis that DTSC requires for the Interim Remedial Action Plan. Of course now tonight we have the drafts of the -- final drafts of the Feasibility Study and Interim Remedial Action Plan for review of the public.

Of course, most of us who have been in the valley for some time now know that there was a known source for perchlorate; that is the manufacturing and storage of testing explosives on the Whittaker property site. Which it's very vague here on this thing, but it's right here.

The water production wells are down gradient, the Saugus water from that site. And then of course we received -- those wells received elevated perchlorate and a little bit of VOC concentrations from that site. So we have started the ongoing remedial investigation, and that goes on today as we talk.

Impacted Wells: Impacted wells; where they are at -- this is very fuzzy thing, this slide. It's not high definition like the Discovery Channel. But anyway, the wells are shown. They are located on the Santa Clara River. The triangles are the alluvium wells, and the circles are Saugus wells, to clarify that. The red dots are the ones that have been impacted perchlorate as I've mentioned earlier. And if you read your handout and look at it very close if you have magnifying glasses you can see the levels that we have witnessed in the testing that we have done over the years of these wells. And basically we will have that -- we don't have that slide Post-it, but if you need any clarification on that, I will be glad to read that later.

Potential Pathways: The studies that the Army Corps of Engineers did in their analysis and Technical Memorandum really kind of signified to us where the pathways are of the perchlorate emanating from the Whittaker site. You see it in the green arrows, and the potential gradient of that contamination you can see as it flows down naturally, down the Santa Clara River flow.

Okay. So who has been involved in all this? We have had the water purveyors, of course, Castaic Lake Water Agency, Newhall County Water District, Santa Clarita Water Company, and Valencia Water Company. We have DTSC, and also the Department of Health Services have been involved with this process that we've embarked on this action plan. We've also had the Army Corps of Engineers. And partly we have been involved with the Whittaker Corporation for the last two years, and Remediation Financial, an interim settlement type arrangement which has now passed. But most of the work that you see here tonight has been discussed with those parties. And the solutions and decisions that we have made as a group involved them at the time. And I will say no more to that.

Now as far as the project constraints, this slide is actually maybe a little confusing, but let me see if I can explain it again appropriately. The project constraints; we have basically two things that we are constrained by in this project. And that's that the perchlorate impact is deep. And that is, we can't really take it out by soil remediation or anything like that. We have to do some pumping. And plus our groundwater production wells are impacted. We want water supply from those wells, therefore we are kind of wanting to use that water beneficially for supply. And therefore, we are kind of limited with that. We have that constraint. So therefore, our need alternatives focused on containment and aboveground treatment. We wanted to contain the contamination, and we wanted to treat it in aboveground facilities.

So the containment criteria that was kind of decided through all the experts the last couple of years is that it was modeled by CH2M HILL in a full-fledge water modeling effort that is part of the record document that we have here in front of us tonight that showed that we can do containment in the Saugus Aquifer by pumping 2,200 gallons per minute, to 2,400 gallons per minute. And then that pumping would be accomplished by Saugus-1 and Saugus-2 wells at an initial rate of 1,100 gallons per well. And the other part is that we can use an existing pipeline to remove that water into a treatment facility.

General Concept: Basically this little graphic shows you pumping Saugus 1 and Saugus 2. Untreated water would go through a treatment system, filtration, perchlorate removal, disinfection, and back into the agency's distribution system as treated water. That's the process, the general concept. Now we get into the alternatives.

So we looked at. In the last couple of years we looked at treatment alternatives of Ion Exchange, the Bioreactor System, and a Membrane Filtration System to remove the perchlorate out of the water.

The Ion Exchange System; basically it's water that's -- first it's kind of roughly filtered. This is so it keeps any sand particles or any other particles that may be in the well that has come through the well screen out of the ion exchange basin. That's what that filtration is about, which they call back filters. And then we go through an ion exchange resin bed, a vessel. And that vessel provides the removal of the perchlorate ion from the water. And then of course that perchlorate ion and its constituents are left on the resin. And the resin is disposed of appropriately as waste. The next part of this is of course we go back through disinfection again, that disinfection today of course would be a chlorination. And then it's raised to the water distribution pipeline system as treated water. It's very simple.

The Bioreactor System is a little bit more complicated. It takes the water from the production wells and then puts it into a sealed vessel. And what you do is you put in a carbon type of straight into this vessel. Bacteria is grown. The bacteria uses up the oxygen from the perchlorate. And then it actually removes the perchlorate ion. And what's left is a chloride solution. And then, of course, you filter the bio solids that are left over and spent out and then you have waste solids to dispose of. And then you of course have to go through disinfection again. And then it has to go through the Rio Vista Treatment Plant. It has to be retreated again as drinking water after this process, using the capacity in the Rio Vista Treatment Plant, of course. The treated water is then distributed and it goes through its process at the Rio Vista Plant, and it's distributed.

Another system to look at, it's been actually a pilot tested, actually bench tested, was from production wells from another filtration process. The water is then put through membranes somewhere, you've heard about it in the reverse osmoses type things. But these membranes have specifically been allocated to the perchlorate ion. And then what happens is that after that's removed that perchlorate is then substituted and then it's a waste product which then has to be disposed of. And then that water is then disinfected again, and it can be treated water.

We are not very much aware of too many of these plants yet operating or that have been approved by DHS yet. But as far as the use of water, it could be very expensive because of the power that we have to generate to take that water through those membrane units and remove those perchlorate ions.

So the proposed system, the group that kind of came to a conclusion on in the last year, is that we will pump the two Saugus wells through the treated system into an ion exchange treatment system. And then, of course, we will filter it and we will disinfect it, and then re-institute it into the drinking water.

We showed the Well Q2. And some of you probably have driven by the Lowe's, and you will see the ion exchange units that DHS is in the process of working with Valencia on improving. It's the same kind of system that we are talking about for Saugus-1 and Saugus-2. It also goes through the same process and can be used as, if Q2 cleans up as some project, that this system could also be used to treat perchlorated water from the Saugus aquifers.

The project: I have very clear poster boards in the back, of the projects. The proposed containment project again, here is the former Whittaker-Bermite facility. This is Saugus-1 and Saugus-2. This is V-157 that is abandoned now. This is the NC-11 down here. There has been some discussions about abandoning NC-11, but that's still not decided yet. And, of course, this is an interim plant. As more information is available we will consider -- those things would be considered in the plan. But right now what the project is, is Saugus-1 and Saugus-2 is located here. And will construct a pipeline between the two wells, then use an existing pipeline, the dotted line that crosses the river, it comes down Magic Mountain Parkway, and a little bit into the bike trail there that's along the

Santa Clara River, down Magic Mountain, down Valencia. Then we switch over and build a new pipeline following this route right here, over into the new well or into the treatment facility at the Rio Vista Pump Station. So this is a new pipeline, and this is a new pipeline here.

So what we anticipate, the capture zone, and this is kind of shown very clearly. This green area is the, if you want to call it the plume, but it's really just taking the number of aquifer levels where the perchlorate is, and then sucking it into Saugus-1 and Saugus-2. But basically pumping it out right there at Saugus-1 and Saugus-2. And the modeling efforts that have been accomplished show that that physically contains the perchlorate contamination.

Before I go to this slide for a minute, of course this assumes actions on the site, also that DTSC is working with the Whittaker group and will continue to do that. And there will be cleanups there, of course. And we are hoping that as time goes on, that that Plume will diminish of course with the pumping.

The Proposed Treatment System: This is the Rio Vista plant as I said, that's right by Lowe's. You're sitting in the Lowe's parking lot looking across at it right now. This would be, looking at the other end, it would be the west end. The east end is right here where Bouquet is. And you can see the units that Valencia has just recently installed. And the pad area is right here in front of the fence, and the facilities will be placed here. The type of facility is like the one that's in Valencia. It's the same size. It's this unit right here. And there's two units by the way. You don't see the other one sitting here.

Operation: What we are going to do is they are always configured in the pump, a lead lag situation. That means that one vessel is always working while the other is a backup, while the flow is going through the first one. And if there was any breakthrough the last lag vessel will catch that and we will not have perchlorate in the water. Then we change out the resin. And the lead unit, make the lag unit go, and then it goes back and forth that way. That's a little bit of treatment. And all this will be operated from the Pump Control Room at CLWA's Rio Vista Treatment Plant. And then we do all our system monitoring, and chemical replacement, and Ion Exchange Media Replacement, which we project to be about a 12-month period.

And then the other part of the operation would be to install new monitoring wells, sort of like the wells that help to see how if the levels of perchlorate is increasing or decreasing as it comes to the wells. And then, of course, we do all reporting necessary to the DTSC, the Department of Health Services, and Community Members.

Operation-Monitoring: We want to make sure that we monitor it, and have an effect in capturing the perchlorate. We will continue to do that, of course, very diligently, working with all the parties concerned. And then the treatment system will of course, we have to evaluate the effectiveness of the perchlorate removal. And I have to say that these units have been -- the ion exchange units have been used -- are in use and permitted by DHS in a number of locations in Southern California. And DHS will be very much involved in this process.

YVETTE LADUKE: Thanks Ken.

Okay. Again my is Yvette LaDuke. I'm the Public Participation Specialist with Toxic Substances Control. And as Sara said earlier we are in the middle of a 30-day public comment period for the interim Removal Action Plan for this project. The comment period ends September 23rd, so we ask that if any of you want to submit any comments, that you do so by the 23rd of September. At the end of the comment period what we will do is we will collect all the comments and we review them. After our review we determine if there needs to be any changes to the plan based on the comments that we received. Once that's done we will prepare a written response for all of the comments that we receive, and we will send those written comments out to everybody who commented. So if you do send in a comment, please make sure that your name and address is legible on the comment so we can get those sent back to you.

Once that process is completed we will finalize the Interim Removal Action Plan, and then we will go ahead and approve it. Throughout this process there will be continued public involvement. As I said, we will then give a written response to comments. And also you can feel free at any time to give either myself or Jose Diaz a call. If you have any questions or concerns about what is going on, you can E-mail me, call me.

Right here, the information Repositories, these are the locations where the Interim Removal Action Plan is located. If you wish to review it before you submit a comment to us, you can go to any of these locations and take a look at it. And again if you have any questions about what you are reading, concerns, or don't understand anything, please don't hesitate to contact us, and we will get an answer to your question.

Right here, "For More Information" that is my contact, and also Jose Diaz, our DTSC Project Manager, his contact information. We are available in the office basically Monday through Friday. So you can feel free to contact us. We will get back to you.

And at this time we would like to open it up for questions. Again if you walked in late please come up to the front and sign in. We have comment cards available. We would like you to fill one of these out if you do have any questions and submit it to us just so we make sure that we have all of your concerns, and we can make sure that you all receive a response.

Also what we are going to do is I have a little portable mike here. What I'm going to do is come around to each of you so that you can ask your question in the microphone, because again, we do have a court reporter here, and we want to make sure that everybody is able to hear your question. And then we will have our panel respond to your question. And if there are any questions that we do not have an answer for right away, we will take your written comment back with us, and we will get you a response.

SARA AMIR: One brief announcement. As we discussed, this is a public meeting for the specific project that we discussed. If you have other concerns about Whittaker-Bermite, or schools, or other concerns, please make sure that you come to us after the meeting and we will discuss those with you. But please make sure that you only ask questions about the specific project that we discussed. We really appreciate that. Thank you.

YVETTE LADUKE: And just to let you know, too, if you do have questions about the Whittaker project there is a meeting coming up on September 14th. It will be in this room at 4:00 p.m. if you would like to attend that.

And now we will open it up for questions. Is there anybody that wanted to submit a speaker card to me?

CONNIE WORDEN-ROBERTS: We've raised the question that I asked Ken Petersen earlier. But I wanted to begin by thanking you for the definitive studies that you've done relative to the water. And there will be other questions that I will have on other subjects later, understanding what you've just said.

What I read in the report had to do with -- and I want to rephrase this so that everyone on the

C-A-C, the Citizens Advisory Committee, can hear the question that I ask. And I was interested in the fact that you were going to close two wells, which are west of Interstate 5. And that's, what the closing meant? That that just meant stop taking water? And what does it mean if there is perchlorate in that as to how that perchlorate will flow? Will it go back? Will it go downgraded? Will it be picked up in another well? Those were the questions that I have.

It seems based on the materials that you've presented and the concepts that were presented this evening are very good ones that will cleanse the water so we needn't worry about that. And I believe that you have already identified the fact that there would be sufficiency of water for the area. And so the question goes back to, when you get an opportunity to do so, talk to the group about what happens to the closed wells, as to downgrading with respect to the perchlorate.

KEN PETERSON: Thank you for the free --

CONNIE WORDEN ROBERTS: Free advice.

KEN PETERSEN: Yeah, free advice. If I could get to a slide, I could probably talk about this a little bit better. If you want to get to that slide.

The wells that we were discussing, that were on previous slides was 157 which is located right here, and NC-11. NC-11; it's still to be determined if we are going to close that off. But as far as 157, that has been already been closed off. And when we say closed off, to explain that, is that the Department of Health and the local health officials have rules about how you close off wells, especially deep wells like this. And then you fill them up with concrete basically. And then you say that they are abandoned. Then you have to make sure that the casing is destroyed at a certain level, too, at the same time.

So when that happens it was decided that this well is not important, as we have done some modeling efforts as we have talked about previously. Looking at pathways for how the contaminate moves off of the Whittaker site, which is in this green area.

What the modeling has shown is if we pumped at those rates, that would take care of sucking in, as I called it earlier, sucking in the perchlorate into these wells. And then that moves the perchlorate away from down gradient, stopping the down gradient migration.

There is another part of the project which we are considering and working on as an enhancement of our water supply. Replacing the water supply that was taken out by pumping these wells, two wells, when they were pumping in the system, was actually pumping at twice the rate that we were going to pump for containment. So we needed to substitute -- to find a way to substitute that lost capacity. And so we are discussing. And part of the project that's in front of the agency right now is a restoration -- groundwater restoration project west of the I-5, the Magic Mountain area, drilling two wells there, et cetera.

We feel that this area without monitoring, et cetera, that this will take care of any migration of this contaminant to this area where those new wells are going.

The idea here again is that when we put these wells in operation again, we can see exactly how we are containing the contaminant. And then from that point we can do other adjustments to the project.

YVETTE LADUKE: Okay. Next is Ed Dunn.

ED DUNN: Yes, Ed Dunn, Canyon Country. And for those that might not know me, I'm a former Director of the Newhall County Water District NC-11 Well, and a former Director of Castaic Lake Water Agency.

The NC-11 Well has completely been left out, and I am still a customer of the Newhall County Water District, completely left out of the program. And I was on the Newhall County Board at the time that we discovered perchlorate, and we closed the well. And that was 1997. We are starting to approach ten years of no use of that well.

Even though this project is supposed to be jointly by the purveyors, which is Newhall County Water District, and the Valencia Water Company, and the CLWA, and they are all paying in the lawsuits to Whittaker, they are all paying to have this cleanup done, CLWA has taken upon themselves to choose who it wants to treat and who it doesn't. And it's avoiding, even though Newhall County Water District is paying the prices to get their well back, and is talking about destruction of the well, and trading, and possibly building a new well. That well should be treated just exactly like they showed the Lincoln Avenue well on one of the slides. They showed you that Valencia is putting a well treatment on a well. They just discovered this in April, that Q2 Valencia had perchlorate, and by September it's going to have clean water coming out of its well. Newhall County Water District should have had this years ago. The treatment, using the ionization process has been going on throughout the State in numerous places. It's very effective. I'm sure the DTSC knows about it. The Environmental Health

Services approved it. Castaic Lake Water Agency wasted a lot of public funds, and a lot of time investigating the microbial and the biological system, investigating other systems before they would make a decision to use the ionization, which was already proven and accepted. That cost everyone a lot of time.

Now we hear what I call a cockamamie system of long pipes, new pipes being put into the ground to try and bring water from certain wells just to get it into CLWA's hands and into their treatment plant. And some of the pipes, you heard them say that they are going to use existing pipes. I believe that's even illegal. Any contaminated water is supposed to be in Purple Pipes, like the output from sand districts, et cetera. Anything that's not pure water is supposed to be in Purple Pipes. They are going to put it in pipes in the ground that are not Purple Pipes. Then they are going to go through all the expense of these new pipes when every one of these wells' output did go into a main. And the theory of using the individual treatment at wellheads, is because after the treatment, it can go right back into the main. That's what's happening down in La Puente, that's what's happening up in Sacramento, and that's what's happening now at Foothill. That's what should happen also in Newhall County Water

District. I am going to finally take it upon myself as an individual and a customer of Newhall County to contact Whittaker-Bermite. Because if they have me paying for something, for these pipelines that take it from wells all the way over to CLWA, that's senseless. It's senseless delay. And it's an interruption to the community, to the bike trails to able to put new pipes in the ground. It's only an intent in my opinion for Newhall County Water District to get their hands, and control of this water. Not Newhall, but CLWA to get control and their hands on this water. And they are ignoring the Newhall County Water County District Well. I think this is wrong. I think they should take the shortest and the least expensive. Use what is proven. They sure can do it for the Valencia Well in just six months. But they can't do it on the Newhall Well ever since 1997.

The water that's in the -- the contaminated water that is in the ground in the Saugus to the Newhall Well or to any of those well like they show the green there, but don't show it going to the Newhall well, the only way that water can come out is to pump it out. There is no new source of perchlorate or Bermite. They are not there making fireworks, or rockets, or ammunitions. So as we pump it out, like it was explained by Mr. Petersen, eventually that is going to diminish. If it is too deep in the soil, that Bermite, then we are going to wait and just pump it out at the wells. So we need the wellhead treatment. We need it now. Newhall's waited since 1997. I think DTSC and the Department of Health Services should take a look at that.

Anybody can have any consultant bottle what you want and make it look like it should go the way you want it to go. But look at the practical part of it. And the practical part of it is that well, Newhall-11, needs to have its own system now to clean it up. And I am going to see if I can do it individually.

SARA AMIR: Thank you for your comment.

One of the issues that you raised was that why they didn't do it immediately. We had to do a lot of investigation and make sure that if they pump those wells, it's not going to exacerbate the plume, and the modeling, and all the work that is being done. Now we have information that we can actually go ahead and let them know that they can pump these wells. And I just wanted to respond to that. But thank you for your comments. We are going to take a look at it.

ED DUNN: Okay. Very good.

YVETTE LADUKE: Okay. Next is Cam Noltemeyer.

CAM NOLTEMEYER: Cam Noltemeyer, Valencia. Yes, I understand from Mr. Petersen's comments that the reason that you were doing that is that the soil cannot be cleaned up. And that's my understanding from being at the (RAP) meetings for soil cleanup, is that it's so deep that it can't be cleaned up. And I believe that's what he said. And that means that the soil in certain areas is so deep, that perchlorate, the contamination, that they actually can't clean it up. And apparently that is why you are doing this interim or (IRAP). I don't understand why we have this interim (IRAP), and why the Valencia contaminated wells aren't being included in this. Because Mr. Manetta, when I brought this up at a C.A.G. meeting had said that it is going to be included, because it was kind of done very quitely. Though they've never had a public meeting about it. And that's the water that I'm supposed to be drinking. I don't drink their water. I don't think many people in this room do drink the water.

But my concern is this seems to be rushing through for some reason, and I assume it's for developers. Because that's basically what we are seeing here, is that it's for one development or another that it's being pushed through rapidly.

As far as I am concerned, as a consumer of the water that is coming from Valencia or from Castaic Lake Water Agency, it appears to me that if you can drill two new wells out there where it isn't going to be contaminated, why aren't you doing four? Because I don't want that dumped in my water supply. Like I said, even now we don't drink it. And I don't think there is anyone in our neighborhood that drinks the water. But yeah, we have to use it for cooking, bathing our children, everything like that. But I'm very much against dumping this even treated contaminated water back into our system where we have to drink it. It seems to me, drill new wells, clean it, dump it in the river or whatever, to let nature take its course on it. But to dump it back into our drinking water is very repulsive to me.

My other concern is that of the cost. On Valencia I questioned this. $500,000.00 is what they said they got from the Whittaker-Bermite. That's like a drop in the bucket. And I know who is going to be paying for it. It's going to be us. And that appears to be what is happening here, too. There's no discussion of who is actually paying for this. I read in the paper that they said that they were going to go after them. Well, we know how that goes. So far I believe it has been the taxpayers that have paid for everything. As far as it came from the Federal Government; fine, that's the taxpayers.

So I am concerned about the fact that this seems to be rushing through before we are doing the -- I believe it's the (RAP) seven through the Whittaker-Bermite.

And again, it's just one of those things where I think it's being done for the Riverpark site. Apparently this water is needed for that. That's in a lawsuit right now. Valencia did it because they need it for a different project. And I don't think the public is really being considered in all of this. And maybe they don't care. I do. And you know, like I said I am really repulsed by the idea of just dumping this water back into our water supply when you've broken --when you are doing two wells out there, why don't you do four?

And I would like an explanation of why they are so anxious to dump something else into our water supply when we already are treating so many things that they are mixing. And when you read everything that they are mixing. I don't know, maybe somebody has confidence in them. I don't think so. I think with what we have seen happen in New Orleans we have lost a lot of confidence in our public agencies. I know that

I have.

So what I really want to know is why can't we just dump this water somewhere else, but not in our water supply? I want to know why the Valencia alluvium wells are not included in this meeting, in this EIR. Did you do a health risk assessment? These other cities that are doing this; has there been a long-range health assessment of how it's affecting those people? I think we go into these things and say, yes, great. We are cleaning it. And yet when you look at the health risk assessments they are practically non-existent. So that's my concern as a consumer of this.

SARA AMIR: Cam, thank you for your comments. There were several questions that you raised, and I will try to answer them.

You mentioned, why Interim Remedial Action Plan. This is interim because the whole thing will be later on in terms of OU-7 for the groundwater at the Whittaker site. So this is part of that. So that is why we are calling it interim. And that (RAP) should be done by the end of this year for the Whittaker groundwater OU-7.

You also mentioned the deep soil contamination. It is correct that there is deep soil contamination on the Whittaker site. But you mentioned that it's not going to be cleaned up, and that's not true. It is going to be cleaned up. But it wasn't under OU-1 (RAP), it wasn't included. It was only shallow soil. So the deep soil will be cleaned up later on. It has to be with some, in C2 remediation because we can't really dig up the old (inaudible) in the Santa Clarita Valley and take them away. So there is a lot of deep contamination, and it will be dealt with.

And you also mentioned, rushing through. We started working on the Whittaker site in 1994. Right now it's 200t and we are doing Interim Remedial Action Plan. I don't think that we are rushing through this project. And so we have done a lot of -- in '97 you mentioned that they found perchlorate in the wells from '97 to 2005. It's been a long time. So it hasn't been rushed through. And the gentleman who spoke before you was criticizing the Castaic Lake Water Agency or the water purveyors, why they didn't do anything right away. And we understand that. We have to make sure that whatever we do is really protective of public health and the environment. And that is why it took a long time to get here.

I hope I've answered most of your questions.

Some of the questions about the cost, maybe Ken Petersen can answer. And about the public agencies and your confidence, I hope that with all the work that we have done in this community we have earned your confidence in our work. Thank you.

KEN PETERSEN: As I discussed earlier in my presentation, the project included a time when you we had an interim settlement with the Whittaker and Remedial Financial.

A lot of the work that you see tonight was accomplished under that remedial action, on the Remedial Action Plan and also on the studies that were accomplished. And those were funded actually by the insurance people for Whittaker. So that was not on the backs of our payers.

Presently, I'm just going to throw out some numbers here. We probably spent about $10,000,000.00 totally on this project so far in studies and analysis. And of that $10,000,000.00 we probably have only -- we've had reimbursements either through from the Whittaker group, and et cetera, almost two-thirds of that presently. We are still proceeding in final settlement with the parties that are concerned. And it's our hope that since we are doing this interim (IRAP) tonight and the feasibility studies that we have been discussing, that the insurance people for the Whittaker people would be glad to pay for the remaining part of the project. So that's how the costs are working out.

YVETTE LADUKE: Okay. And just to let you guys know, too, it might be a little bit easier for us to respond to your questions, I know some of you have a lot of questions, if you ask one question at a time and let the panel member respond, that way you will get a full response to each of your questions. It's kind of hard to remember them all when you have a list. So I will give you an opportunity to ask more than one question. It might be a little easier that way.

Marsha McLean.

MARSHA MCLEAN: Hi, I'm Marsha McLean and I'm Councilwoman for the City of Santa Clarita, however, I'm asking a question for myself, I'm not really representing the entire City Council.

First of all, I just want to say that this land has been contaminated far too long. I'm happy to see that this process -- that these steps are being taken and this process is being implemented. The faster we can implement this and get it finally cleaned up, the better. The citizens of Santa Clarita deserve to have this area cleaned up. So anything you all can do to help expedite this, and what we can do I'm sure is a good idea.

My question is, is when you take this water and it goes through the process, and you are saying that the water, the treated water is going to be put back into use. I'm just wonder, do you have documents at this point, how do you give the citizen's a level of comfort that the water actually is safe to drink? And do you have documentation that shows that previously treated water is safe to drink? I think that's one of the things that we are going to have to do as a public agency, as a city, to assure that this water is safe. And that's, you know, the first part.

The second part is, is how much water are we talking about? And would it be wise to use this water for say watering golf courses and those types of uses rather than to be put back into drinking water?

KEN PETERSEN: The project also includes another public process where we have to get a permit to supply this water as a drinking water source. And DHS is involved in that process. It's called -- they call it after a policy that was passed in 1997. That 97-005. It includes a 12-step process where that we go through analysis, somewhere what DTSC does on public health concerns. And when we do it on the water, we do risk analysis as one of the items on that list that we look at.

That process happens after the project is actually designed so that the agency, the Department of Health Services can review the plans, and make findings about the safety to our health as far as a drinking water source.

The other part of the process is that there is a public hearing involved. The water is actually -- what we are taking away from the water is just the perchlorate ion through a process. And everything else is the same, minerally, constituents of the water. That water is then tested as I said earlier, and monitored, and meets the Federal drinking water requirements as enforced by the Department of Health Services. And so they are our oversight. And we do the testing. As we do today in all waters that we supply to our customers through our treatment plants and the wells that are purveyors ground. So there is another process that will occur before the water is even actually turned into the system.

As far as the recycled water discussion, using the water, the recycled water causes -- needs a lot of infrastructure. And also we need to pump this water all the time. To be effective as a containment we would have to pump the water on a 24-hour basis, 365 days a year to achieve the containment scenario that we want.

Recycled water is, of course, oriented around landscaping usually, golf courses. And you know, as of this last winter you don't turn on your sprinklers a whole lot and use any water when you got nature helping you. So that's why the feasibility of using recycled water was kind of put aside. In this event, we needed to pump the water all the time, is how this goes, to be effective containment.

YVETTE LADUKE: Those are all of the speaker cards that I have. Are there any other questions out here?

And before you ask your question if you would please state your name, and then one question at a time please. And we will let you ask more than one.

JOAN DUNN: Okay. Well, these are basically statements. I'm Joan Dunn, and I am a Water Director on the Newhall County Water District, and I'm speaking for myself.

And in hearing some of these answers, the item that I thought was interesting is I think that Cam Noltemeyer was right about the Q2, the Valencia well, how quickly that seemed to go through, and the others are kind of on hold, and this one is going through. Well, they said that it's because it's an alluvial well. Well, whether it is or isn't, it's being done right now.

Now the other item, and that's just a statement, but VOC, you folks are very free with these things, and I don't go to all those meetings, but I don't know what VOC stands for.

SARA AMIR: Volatile organic compounds.

JOAN DUNN: Thank you. They probably should have in their diagram here, you know, qualify that.

SARA AMIR: Yes.

JOAN DUNN: And then the other thing that I wanted to make mention of is CLWA, and ask Mr. Masnada, I have heard him talking about that we are just going to go ahead and do the pipe system. And that sounds like they have already made up their mind. That's what they are going to do, no matter who does what. And I thought that's pretty interesting because -- they're kind of arrogant anyhow, so it wasn't surprising. But anyway, I have that on tape if you don't believe me. Anyway that was my last comment.

SARA AMIR: I know that you didn't ask questions, but regarding your last comment, we are going through a public process. And there is CEQA also with this process. So everyone gets to comment. And this is not a done deal.

YVETTE LADUKE: Okay. Cam.

CAM NOLTEMEYER: I don't believe I received an answer. And I did receive this in the mail, you know, as far as giving comments. And in here it says actions to respond to perchlorate contamination into alluvia water supply wells are being considered separately. Those are the Valencia water wells. And they are not being considered under this environmental mitigated negative deck. When are they? When will we have a right to say something about what is going on with the Valencia Water Company?

When I asked about that, you know, you all acted -- you being Jose and everyone at the last meeting I was at, that you didn't know anything about it. Then they did finally admit that there was an agreement between the DTSC, and Whittaker-Bermite, and Valencia Water Company. But where was the public involved in this? And since you state right in here, actions are being considered separately, when are they going to be considered, and when will the environmental impact report be presented to the public on the Valencia water wells? Because I have to drink that water. Well, I don't drink it, but --

SARA AMIR: This is a public meeting for the project that we talked about. I'm more than happy to talk to you after the meeting about the Q2 well and other wells.

But we want to really restrict our comments, and questions, and answers to this specific project. There is a court reporter here recording everything that is being said regarding this specific project. And next week on the 14th we can talk about it, or after the meeting. But I would really appreciate it if you would keep your comments to this specific project.

CAM NOLTEMEYER: Then I guess my comment is, why is the cleanup of the contaminated water being piecemealed in this way? It seems to me that it should be that all of it should be considered, not piecemealing it in the manner that they are doing right now. And that concerns me a lot.

And also I am concerned about whether you are really containing the plume of what you are doing. The fact that it has spread to other wells already indicates that you haven't. And there doesn't seem to be any guarantee of what you are saying here that they're actually containing it.

I would like to hear from the Corps of Engineers, or people that we have been giving all this money to, to tell us exactly if they think this is going to contain the plume, and spread.

YVETTE LADUKE: Okay.

ED DUNN: I just wanted to further comment on what my wife said about the General Manager at CLWA. I find it interesting that this is a public hearing for input on this project. And this project from what was described here tonight is this big expense of all these pipes going to take a tablet of wells down to CLWA's property and then treat it there so it can go into CLWA's pipes.

And what the General Manager said when this was presented at the Engineering Committee Meeting, or else it was their Board meeting, but one of the two, he said, "We are going to go ahead with this no matter what." And the indication was, it didn't matter whether Bermite would pay for it or agree with it, or whether DTSC or anyone else would agree to it. They were going to go ahead with it. So I find it interesting that we are having a public hearing about this project when someone else has already made that decision of what they are going to do. And that's what goes on with this particular agency.

YVETTE LADUKE: I think we have a responds back here.

DAN MASNADA: I'm Dan Masnada, the General Manager of the Castaic Lake Water Agency.

The point that I made once or twice before, I can't remember if it was at a Board or a committee meeting, was simply that the Agency and the purveyors were committed to going ahead with the containment and the treatment regardless of whether we obtained the funding, or when we would obtain the funding from the polluters, recognizing that the containment was necessary to protect the environment and to protect the Saugus formation.

That's it in a nutshell. Thank you.

YVETTE LADUKE: Do we have any other questions?

ED DUNN: I will provide him a copy of the tape of what he said, in video.

YVETTE LADUKE: Okay. Cam.

CAM NOLTEMEYER: Can I get a reply to my question? Can we hear about whether this going to --

SARA AMIR: The questions that we cannot provide the answer tonight, will we provide them in writing to you. Not all of the questions can be answered tonight.

YVETTE LADUKE: Okay. Are there any other questions?

PUBLIC PARTICIPANT: Circle J Ranch Estates, which seems to be sitting underneath or on top of the plume. And I am wondering if the whole idea is to keep that plume from spreading further off into Saugus, off into Valencia. Right now it looks like we are getting the benefit of it all. And I wonder what the environmental studies have shown about the people who are actually -- we are just underneath the Whittaker property. And what does anybody know about the impact on us? I don't know whether those two wells, Saugus Wells 1 and 2, did you say, are our wells, or the one down in Newhall which has been waiting since 1977. Or if my geography isn't quite right, but I think that green area is Circle J Ranch, or mostly. And what are we drinking while all this cleanup is proposed? What have we been drinking?

SARA AMIR: I just want to mention that the green area that you see, this is in the groundwater, it's not in soil. So you are not being exposed to perchlorate. This is showing that when those wells are being pumped, its perchlorate contamination will go into those wells and will be cleaned up as containment, so that the perchlorate will not end up going further to the east area. So it's a containment system to contain the perchlorate contamination in groundwater in the area that has been affected, and not going further. But you had a question about what you have been drinking.

PUBLIC PARTICIPANT: Well, you are talking in the future tense; this will be when it's contained. I'm sort of interested in the past.

SARA AMIR: It has affected those wells. We know that.

PUBLIC PARTICIPANT: And those are our wells? Serving our area?

SARA AMIR: But you haven't been drinking the water. Those wells have been shut down.

PUBLIC PARTICIPANT: When were they shut down?

SARA AMIR: In '97, '98. 97.

PUBLIC PARTICIPANT: Okay. We've been here since '88 I think our development; '87, '88. So that's ten years earlier.

SARA AMIR: That was the first time that perchlorate was detected in the well, and that was the time that it was shut down. So the previous monitoring did not show any perchlorate.

PUBLIC PARTICIPANT: So it's not in our drinking water, it's just in the soil?

SARA AMIR: It's in the groundwater, and it's deep soil, but you are not drinking that water;

PUBLIC PARTICIPANT: Okay. Thanks.

YVETTE LADUKE: Does anybody else have any questions? Okay. With that I want to thank everybody for coming out tonight. Again, if you didn't get a chance to sign in, we ask that you please sign in. And that we have your current address so we can make sure all of you are on our mailing list and we have your current address so that we can make that our information gets out to you. And again, the comment period ends September 23rd, so if you have any comments that you would like a response, please make sure that you get that into us.

Thank you.

______________________________)

Public hearing of Castaic Lake Water Agency at 27234 Bouquet Canyon Road, Santa Clarita, California, commencing at 7:05 P.M., Wednesday, September 14, 2005, before Laurie A. Schmidt, Certified Shorthand Reporter No. 12719.

SANTA CLARITA, CALIFORNIA

WEDNESDAY, SEPTEMBER 14, 2005

7:05 P.M.

PRESIDENT PECSI: The next item, 4.1 is a public hearing on the Groundwater Containment, Treatment and Restoration Project Mitigated Negative Declaration. General Counsel, Russ Behrens and Operations Manager, Ken Petersen are here to assist. Mr. Behrens.

MR. BEHRENS: Yes, Mr. Chairman, members of the Board. Tonight's public hearing is on the Groundwater Containment, Treatment and Restoration Project. And this is the next step toward completion of the CEQA process. We are having a public hearing tonight, and the staff requests that the Board consider whether or not to certify the Mitigated Negative Declaration, and adopt findings and related documents to complete the CEQA process after the completion of the public hearing. If the Board certifies the Mitigated Negative Declaration, then it may consider whether to authorize the Project to proceed to construction.

After the staff completes their presentation to the Board, then the Board can address its questions to the staff.

And then after the Board's questions are answered, then we will proceed into the hearing.

After the public completes their comments, the Chairman should then close the public comment portion of the hearing. And then the staff would recommend whether to consider the certification of the Mitigated Negative Declaration. Comments made tonight by the public at the hearing should be considered by the Board as part of their deliberations on whether or not to adopt the Negative Declaration, Mitigated Negative Declaration.

Are there any questions about the procedure?

PRESIDENT PECSI: Any questions for Mr. Behrens?

All right. Thank you. You may proceed with the presentation, Mr. Behrens.

MR. BEHRENS: Thank you. Ken Petersen is here tonight. He is going to describe the project and the CEQA process that we went through to develop the Mitigated Negative Declaration. And I just want to point out to you, we received some compliments on the Mitigated Negative Declaration. This is just the initial study that was prepared by Ken and his staff. And it's very, very complete. It's very detailed. And the compliment was that it was a very sincere effort.

It's very transparent as to what we are doing, and what we are trying to do, and the purposes of it. So I just wanted to share that with you before Ken took the mike, because he won't tell you.

PRESIDENT PECSI: Good job. Thank you.

KEN PETERSEN: Well, tonight I will provide the project, an overview of the project, the purpose of the project, what the components of the project are, and then a little bit of background on what we have gone through with the Negative -- the posting of the Negative Declaration, and the pending adoption here.

First off, the purpose of this project is that groundwater supplies and production of the Saugus Formation and the alluvial aquifer in the valley, downstream of the Santa Clara River are currently threatened by the Whittaker Corporation Bermite facility perchlorate contamination caused by their previous business activities at that site for up to 80 years now.

Today we have five production wells that have been taken out of service with the total capacity of 8,700 gallons per minute, and an historic annual production -- with an historic annual production of 5,300 acre feet per year. Without a program to contain the thread of the contaminated water going into the vicinity or from the vicinity of the Whittaker-Bermite property, perchlorate is expected to migrate further downstream and contaminate other wells and portions of the Saugus Aquifer.

So to address this perchlorate contamination, it's necessary to prevent two things -- three things that we have to do is contain this migration, and prevent it further from going downstream, treat any water that's extracted as part of the containment process, and recover lost groundwater production. That's what we call production restoration.

To accomplish these objectives the proposed project has two functional elements. Containment, treatment facilities; that's one element. The other element is service restoration facilities.

Let me explain the containment facilities. In front of you we have a figure from the Initial Study, Figure No. Five.

MARY LOU COTTON: Yeah, it's Five.

KEN PETERSEN: Thank you. So the facilities that we contemplate is two Saugus wells which are located at this location, and this location here. You know, you would think I --

JERRY GLADBACH: It's hard to see that point.

KEN PETERSEN: Yeah, I know. Let me do this.

I'll do it a little bit differently.

JERRY GLADBACH: Yeah, there we go.

KEN PETERSEN: Okay. The figure that I really want to get to is this one. That's what confused me a little bit.

Okay. The project, this is the containment facilities that I am going to talk about first. It includes the two wells; Saugus-1 and Saugus-2. That's to add new pumps, variable speed to pump 1,200 gallons per minute. Each flow into pipelines, et cetera. And I will go through that. We are going to put -- this project also contemplates a network of monitoring wells north of the system, meaning in this area. Some wells have already been drilled but we need to do more for the monitoring of contaminants as it comes off the Whittaker site. This is the Whittaker site.

The groundwater gradient flows this way down the river, and that's what I expect the contamination flow is, from this direction. These wells are located in the prime spots for pumping hydraulically the contaminates away from downstream migration of the perchlorate in this area.

The other project as -- part of the project is for the containment facilities, is to built pipelines to transfer the water that's been pumped out of

Saugus-1 and Saugus-2 in this new green -- existing green pipe sitting here, into a new or existing pipe, Agency pipe right here, up to this point, and then the brand new pipeline in the solid line, to the Rio Vista Pump Station which is located here where the line is, right by Lowe's and In-N-Out.

This line is contemplated to be in bike trails, paved areas. It's contemplated presently to be in the bridge of Bouquet, the new section of the bridge which we are working with the City, of course, if that's capable. But this project provides that opportunity to do that.

The other pipelines that are shown here are existing Agency pipelines in red. And that's just for reference purposes on this part of the presentation.

The treatment plant is, of course, going to be a one-train, two-vessel ion exchange system using a PWA two strong based Ion exchange resin followed by chlorination, disinfection for the capacity of 2,400 gallons per minute. And it has the capabilities of adding more units on it in the future.

The last part of this process is, of course, the conveyance from the treatment plant itself, and it has what would be provided in the treated water lines of the Agency at this point, or we are looking at other alternatives, too, for distribution of that treated water in the Agency's system downstream. We don't show that here on this.

The second part of the project is the facilities for the restoration of service. As I said earlier we are only going to pump 1,200 gallons a minute each, that's 2,400 gallons. But we need a capacity of, as I said earlier, of 8,700 gallons per minute. So we are going to make up that capacity lost in wells on what we call the west side of the valley; Saugus wells.

And let me go to the next slide and I will show you that. This is the actual pipeline system. Let me go to the wells itself, and then we will work east. The wells are located near Magic Mountain Parkway. It contemplates two wells presently with a combined capacity of 4,000 gallons per minute. The construction would be in an unpaved area, in this area right here. And this is the park, of course, the Magic Mountain Park, Amusement Park. These are basically in an area that there is an existing well here that was recently drilled by Valencia Water B-206, which is in the Saugus Aquifer, and these two wells will also be in the Saugus Aquifer to provide that capacity.

That contemplates new pipeline to here, down this area, and paved roads. One eventually will be developed in this area. The pipeline would be extended from the Agency's system presently. It's being extended right here by another project that we are working on called, Magic Mountain Pipelines. And eventually it will be extended all the way up here. And when that happens we will be able to convey that water, that supplied water into this pipeline and bring it up back to where the points of Saugus-1 and Saugus-2 are. And I will get to that.

JACQUE MCMILLAN: Is that the 126, or what is that?

KEN PETERSEN: This is Magic Mountain Parkway right here.

JACQUE MCMILLAN: Right there; okay.

KEN PETERSEN: And there is the realigning of the Old Road right here. I kind of drew that in there. This is the development that's being planned presently above Magic Mountain. And eventually there will be a -- we are also -- this is not part of this project, but there will be a reservoir over here eventually. We haven't decided it exactly yet. That would be Castaic's. And that is another environmental work.

All right. Back towards the east. Now there is Saugus-1, and there is Saugus-2. And Saugus-1 is a little bit out of the picture right now. But it's contemplated to, as we have taken out pipelines to use for the perchlorate water, we are going to replace them with larger pipelines that will provide the capacity that has been lost by these two wells and bring it back to locations for turnout to Santa Clarita Water to replace their system, and also to bring -- the project contemplates new pipeline down the bike trail from McBean Parkway. That will bring in more capacity, that capacity that we were just discussing earlier from the wells. And that capacity would then be put in two new pipelines going to this point, and also to replace capacity for NC-11 down south here along the bike trail. You can see here, this is the new pipeline that would contemplate.

This pipeline in the red will still exist, and that's why we received further capacity augmentation in this part of the system for replacing NC-11. The project also contemplates, which is not on the map here, a replacement well for the Stadium Well, a new 800-gallon-per-minute well, and it would be probably up to 100 feet along the pipeline for connection in the Furnivall area of Canyon Country, or I guess it's called the Honby area. Yes, the Honby area.

So what I have done is gone through the

description as described in the CEQA Initial Study document.

Now I can get into, if there is anymore questions I would be glad to answer on this part of project.

PRESIDENT PECSI: Mr. Gladbach.

JERRY GLADBACH: Two questions. Where is the treatment plant going to be located?

KEN PETERSEN: At the In-take Pump Station, on Rio Vista right by Lowe's.

JERRY GLADBACH: Okay.

KEN PETERSEN: And I have quite a slide for that, but I didn't bring it. I didn't make it part of the presentation.

JERRY GLADBACH: Okay. And then the other question. Are we not going to, or is Newhall County Water District not going to pump from their well that's been --

KEN PETERSEN: Well, that's still out right now.

JERRY GLADBACH: Okay.

KEN PETERSEN: It's still being studied. But this solution, this project contemplates replacement water through pipelines for replacement of that well if it's not being used.

PRESIDENT PECSI: Director Cooper.

BILL COOPER: Mr. Petersen, the migration of the perchlorate going towards the west, what about migration of the perchlorate off of the site coming off of the Stadium area, the train station, towards the river in that direction? No cutoff wells going in there?

KEN PETERSEN: As far as this project, no. This project contemplates our containment of the Saugus Aquifer pollution. The situation on the north side of what I would call the north side of the -- let me get to PDF-4 here.

Director Cooper was asking about what is going to happen with the perchlorate that's been found in alluvium wells in the -- Well, actually in the alluvium wells in the Santa Clara River where I am pointing right now. Coming off the site this way basically. The situation is that that is under a different -- it's under OU-7 of the DTSC, and they are contemplating various solutions to that situation for that. There is some thought that pumping Saugus-1 and Saugus-2 will draw some of that perchlorate into, and get it out basically, and provide a hydraulic system to stop the plume from raising. But alluvium is such a porus media, and the perchlorate in the water just goes right through it basically. So the idea is that we are, DTSC is studying that and working with the property owner or representatives, and working towards solutions for that. But this project does not contemplate that solution.

BILL COOPER: Thank you.

BOB DIPRIMIO: If it's okay, I just wanted to add to Mr. Petersen's response. It's not about this project, it's about the Northern Alluvium Containment.

DTSC has reviewed an Internum Action Plan prepared by Whittaker to install some extraction wells in the hot spots up in the Metrolink Station area. Those wells have been constructed and installed, and they have an on-site treatment plant that will be operated, and will pump those wells in small volumes but remove a lot of perchlorate because there is a highly concentrated area there. And so that will provide some containment in the source area that they've found thus far. And that treatment should be online probably by October, November of this year, so we will begin to see some containment and control in the Northern Alluvium. It's an interim measure, but it's something that Whitaker and DTSC have responded to primarily because of the Water Company's insistence that something happen there sooner than later.

JACQUE MCMILLAN: What happens to the treated water, is it reinjected?

BOB DIPRIMIO: No, the treated water I believe they are going to use the same technology that we are using. And it will be discharged to the Santa Clara River. So we will remove the perchlorate and discharge it to the river.

PRESIDENT PECSI: Mr. Manetta has a comment.

WILLIAM MANETTA: Yes, there is also another process that they are working on up in that area. It's called in situ Bioremediation. Shaw (phonetic) Environmental is doing the pilot study now, or preparing for one, which will basically put bugs in the ground that will be eating the perchlorate before it leaves the site. So that's part of the process to keep the site from oozing this perchlorate into the river. Once it hits the river it dilutes and moves rapidly west. So the best way to get it is at the source.

BILL COOPER: Any thoughts of a cutoff wall?

MR. MANETTA: Well, I brought that up to one of their experts. They did punch tests on the Manelli's (phonetic) property just south of the -- excuse me, just west of their parking lot here on the screen, about six or seven punch tests across their property. And they say the ribbon of the plume is very narrow. And that three or four of the punch holes showed perchlorate, but as you move further north there was nothing there. And they thought that there was the possibility that they may put one or two wells at that point if they can't get it all with the method that Bob was talking about.

KEN PETERSEN: And I'm outlining where the perchlorate is actually. And of course, this is where Q2 is right here. And it still is an anomaly as far as all that came here. So Basically that's where the ribbon of perchlorate is as it comes out. And the idea is that these wells will have some contact with alluvium, but we still have to do more. That's almost pretty consistent with the technical --

PRESIDENT PECSI: So that concludes the project description portion?

KEN PETERSEN: That's correct.

PRESIDENT PECSI: Thank you.

KEN PETERSEN: Now as far as what's in the document that you find in front of you tonight, the mitigation measures that's been incorporated in the project, let me just kind of review that very quickly.

We have, the first item is the facility site selection. We are extent feasible. We have sited the projects on existing sites, Saugus-1 and 2, for instance, using roads for construction or existing bike paths where most of the pipelines and wells for service are combined to existing roads, or will be in the future constructed in new roads.

As far as the areas that -- all the areas that had previous activity and has removed all wildlife habitat roads due to that, I guess. About 40 percent of the pipeline to be constructed for service restoration would be within the alignments of the regional bike trails, and thus minimize -- thus take away the -- or reduce some of the traffic impacts. The construction schedule will coincide with what is typical of this area. We will try to stay out of the river when there is habitat or nesting periods going on. We have done some studies of that presently, or research. We have done -- we have looked at river crossings. And that we will do these things in relationship to the existing CLWA pipeline,, thus minimizing any impacts that we could have in the river bottom.

As far as the South Fork of the Santa Clara River, we are using existing piping, and we also will be jacking in pipe under the river. And that's in this area right here.

We will use Best Management Practices when constructing public Right-of-Way, working with the City of Santa Clarita Transportation and Engineering Services getting encroachment permits, and coincide with their policies. We have also, if there are any County of Los Angeles roads that we would be building in, such as on the west side of the I-5, we will do the same.

As far as Best Management Practices for construction of bike trails, we will construct no more than one section, or take one section of the bike trail out of service at any time, and work with the local bike enthusiasts and the City and make sure that detours are clearly marked.

The aesthetic treatment of the water treatment plant at the Rio Vista In-take Pump Station presently will match the decor that we have there, which is the Spanish-American architecture. And we will try to make that blend into the -- or we will make it blend into the aesthetic visual character.

Air Quality: We will adopt best management practices to control due to the dust from construction, and comply with the South Coast Air Quality Management, Table 1, as it's stated in the report.

The noise of the project will contribute to the siting of the project, it will contribute to avoidance. We will avoid noise impacts to adjacent businesses and residences. Containment facilities will be constructed to residential development. And the majority of containment facility pipelines will be separate from the nearby commercial development by major arterial roads. As far as construction is concerned, we will have construction crew training, on-site biological monitoring, and isolation of the construction area away from habitat areas.

We will comply with all water quality best management practices for avoidance of construction runoff, construction activities. We also will ensure that the construction scheduling and potential construction will not impact cultural resources, and will manage all potential cultural resources through excavations, and not to extent to undisturbed soils. And of course, we will comply with all DHS requirements.

The mitigation, the Notice of Intent to Adopt the Mitigated Negative Declaration for the project was put out in the street. It was sent to the State Clearinghouse on August 23rd. The review period ended September 23rd. The project notices were provided here at this site. Library copies of the project documents were provided at the Darcy Library and the Valencia

Library. And also I personally had posted notices four or five different places along the route of the pipeline at the two wells here at this site for notice. With that, I will be glad to answer any questions.

PRESIDENT PECSI: Thank you. Are there any questions concerning the staff's presentation? Director Diprimio.

BOB DIPRIMIO: Ken, is there another environmental process related to this project just on the treatment system? Or maybe to say it another way, for 9705? Or is this the environmental process for the whole project, and there won't be any other?

KEN PETERSEN: That's correct. This is the complete project that contemplates the 9705 permit. This is the CEQA for that, and also for the (IRAP), Interim Remedial Action Plan for DTSC. This is the environmental work for that.

BOB DIPRIMIO: Thank you.

PRESIDENT PECSI: Director Campbell.

DIRECTOR CAMPBELL: I just wanted to point out that DHS will require public hearings as part of their 97005. It's not CEQA related, but they will require public hearings under that process.

BOB DIPRIMIO: Okay. Then I've got a question for either Tom or Ken. If that's the case, then based upon public input, could the project change as a result of DHS's own process?

KEN PETERSEN: We are pretty far along with the DHS process. And I would say always it can be changed by DHS. But DHS will not approve the project until they have the public clearing, and the design is complete.

BOB DIPRIMIO: And maybe it's also true to say that their focus will be on the treatment plant only, and not the pipelines and the replacements.

KEN PETERSEN: That's correct.

BOB DIPRIMIO: Okay. Thank you.

KEN PETERSEN: And the groundwater restoration part of the project is more oriented to bring back the capacity that's been lost on the system with the reduction of Saugus-1 and 2, NC-11 and 157.

PRESIDENT PECSI: Director Gladbach.

JERRY GLADBACH? Ken, at what point will DHS -- I assume that they will have their own public hearings then on the treatment process?

KEN PETERSEN: Yes.

JERRY GLADBACH: And when will that be? I mean --

KEN PETERSEN: Well, it happens pretty close to almost as the project is constructed actually.

JERRY GLADBACH: Really?

KEN PETERSON: We are ready to turn the switch. And then they will have the public hearing and consider all the -- they will give us an interim design approval and construction approval, but the process ends when they have the public hearing, and they give you the water permit.

PRESIDENT PECSI: Any other questions, comments by the Board for staff? Good. Thank you. Thank you for a comprehensive presentation on the project.

Okay. We will now open the public hearing portion of this for the Groundwater Containment, Treatment Restoration Project Mitigated Negative Declaration.

Are there any members of the public who wish to comment on the Project Mitigated Negative Declaration?

Thank you. Hearing none we will now close the public hearing portion of the meeting.

Are there any comments from the Board based upon the comments we heard?

Thank you.

The next step is to consider certification -- Oh, I'm sorry.

Resources Code, and that the Board has carefully and thoroughly reviewed the proposed Final Mitigated Negative Declaration and Initial Study which you've previously received. We didn't hand those out again to you tonight because of the volume and the waste of good taxpayers' money for making extra copies, but you've receive this previously. There is a couple of copies here for the public, and the staff has theirs which will be attached to this Negative Declaration. And that the Board has determined that the Project can be approved because there is no substantial evidence in light of the whole record that the Project may have a significant effect on the environment.

And the next recital is that. And that's because the Board has evaluated this on their own independent judgment.

So then we get into on the second page the action that you are taking. And you find that the document was prepared consistent with CEQA. And the Mitigated Negative Declaration reflects the Agency Board's independent judgment and analysis that you do hereby adopt the Final Negative Declaration, Mitigated Negative Declaration, and that you adopt the findings, which are Exhibit D, which are actually a part of the resolution and not attached, but they are part of the resolution. And we will go into that in a minute. And the Board finds that the findings are supported by substantial evidence in light of the whole record, and does certify this Final Mitigated Negative Declaration to be accurate and complete as well as legally sufficient pursuant to the provisions of CEQA. And you do direct the Agency staff to promptly file a Notice of Determination with respect to the project.

The location of the records are here at the main offices on Bouquet Canyon Road, and that you resolve further to adopt the Mitigation Monitoring Program which is attached as an exhibit, Exhibit C, and is consistent with the Public Resources Code Section 21081.6. And that you adopt the Mitigation Monitoring Program, and that the General Manager has authorized to execute all documents required to carry out this Mitigated Negative Declaration.

Then the Exhibit D Findings are set forth here, one through eight, which repeats the information that we have just gone over in the Resolution.

You have met all the requirements. Finding No. One is that you've complied with CEQA. Finding No. Two is that you have met all the requirements for public review, and including this hearing tonight. And no new issues were raised.

That the Final Mitigation Declaration contains all the information required by the Public Resources Code and the CEQA guidelines.

Finding Four: The Agency met all the requirements for notice for the September 14th hearing tonight.

Finding No. Five: The Initial Study meets the requirements of the Public Resources Code and the CEQA guidelines.

Finding No. Six: The Initial Study contains no evidence that the Project, with mitigation specified, may have a significant effect on the environment.

Finding No. Seven: The Agency is the proper lead agency for preparation of the Mitigated Negative Declaration under the Code and under the Guidelines.

And then finally and last, Finding No. Eight: It is found and determined that the Project will not have a significant effect and impact upon the environment, and is consistent with the Code and the Guidelines. And for the preparation of this document and for proceeding with the project.

And that the action taken tonight is a result of the Agency Board's independent judgment.

So with that you will find then attached after the findings, the Final Mitigated Negative Declaration which is a summary of what you heard from Ken. It's in a little more detail.

After that you will find the written comments that we received.

And then after that you will see as Exhibit C, the Mitigation and Monitoring Program. And it's set out in tabular form which is easy to handle. And then as well as laying out all of the mitigation measures that are going to be implemented. It also has a tracking system for who's responsible for what attached to it, which makes it a lot easier to monitor and to assure that the progress is made, and the protections that you want are implemented.

So with that, Mr. Chairman, I have nothing further to add unless there are any comments.

PRESIDENT PECSI: Thank you. Thank you for the overview on Resolution. Do the Board members have any comments or questions regarding the Resolution?

Hearing none I will now entertain a motion to adopt Resolution 2429 to certify the Mitigated Negative Declaration for Groundwater Containment, Treatment and Restoration Project.

Is there a motion?

(This Page Intentionally Blank)

ITEM NO. 4.1

RESOLUTION NO. ____
ADOPTION OF MITIGATED NEGATIVE DECLARATION
CASTAIC LAKE WATER AGENCY
GROUNDWATER CONTAINMENT, TREATMENT
AND RESTORATION PROJECT

WHEREAS, the Castaic Lake Water Agency circulated for public comment a proposed Mitigated Negative Declaration and an Initial Study on its proposed Castaic Lake Water Agency Groundwater Containment, Treatment and Restoration Project ("Project") to prevent further downstream migration of perchlorates (containment), treat any water extracted as part of the containment process (containment), and recover lost local groundwater production (production restoration);

WHEREAS, the said Agency received written public comments during the comment period from August 9, 2005 to September 8, 2005 on the said proposed Project;

WHEREAS, the Agency scheduled a public hearing on the proposed project at its Board Room, 27234 Bouquet Canyon Road, Santa Clarita, CA 91350 for September 14, 2005 at 7:00 P.M. for purposes of considering the public comments as part of its decisional process concerning the proposed Project;

WHEREAS, pursuant to Public Resources Code section 21092.5 the public hearing did not constitute an extension of the public comment period, and no responses are required under said Public Resources Code section to comments made because the hearing was scheduled after the close of the public comment period;

WHEREAS, this Board has carefully and thoroughly reviewed the proposed Final Mitigated Negative Declaration and the Initial Study (Exhibit "A" to this Resolution), all public comment period comments pertaining thereto (Exhibit "B" to this Resolution), and the Mitigation and Monitoring Plan (Exhibit "C" to this Resolution), all of which documents are hereby attached as exhibits to this Resolution, and thereby incorporated herein by reference into this Resolution;

WHEREAS, as a result of public comment period comments and comments made at the public hearing on September 14, 2005, the Agency's Board has determined that the proposed Project can be approved because there is no substantial evidence in light of the whole record that the Project may have a significant effect on the environment; and

WHEREAS, the Agency and its Board have considered all of the information presented to it as set forth above and this Resolution and action taken hereby is a result of the Board's independent judgment and analysis.

NOW, THEREFORE, BE IT RESOLVED that this Board of Directors of the Castaic Lake Water Agency does hereby find and determine that the Final Mitigated Negative Declaration was prepared pursuant to the provisions of CEQA, that there is no substantial evidence in light of the whole record that the Project will have a significant effect or impact on the environment, that the Final Mitigated Negative Declaration reflects the Agency Board's independent judgment and analysis;

RESOLVED FURTHER that the Agency's Board does hereby adopt the Final Mitigated Negative Declaration attached as Exhibit "A" to this Resolution and does hereby approve the Project;

RESOLVED FURTHER that this Agency's Board does hereby adopt the attached findings (Exhibit "D" to this Resolution) which the Agency's Board finds are supported by substantial evidence in light of the whole record, does certify this Final Mitigated Negative Declaration to be accurate and complete, as well as legally sufficient pursuant to the provisions of CEQA, and does direct Agency staff to promptly file a Notice of Determination with respect to the Project;

RESOLVED FURTHER that the location of the Agency's record on this matter is at the Castaic Lake Water Agency, 27234 Bouquet Canyon Road, Santa Clarita, CA 91350 and the Custodian of the Agency Record is April Jacobs, Acting-Secretary to the Board of Directors;

RESOLVED FURTHER, that the Project's environmental review process identified numerous mitigation measures designed to prevent potentially significant impacts that might occur. These mitigation measures either have been incorporated into the Project or specified in the Initial Study, and will be monitored and enforced pursuant to the Mitigation and Monitoring Plan ("MMP"). The MMP includes the feasible mitigation measures for potentially significant direct Project impacts that are within CLWA's jurisdiction and authority to enforce. The MMP is required by Public Resources Code section 21081.6 and is attached to this Resolution as Exhibit "C" and is incorporated herein by this reference;

RESOLVED FURTHER, that the Agency's Board does hereby adopt the MMP; and

RESOLVED FURTHER, that the General Manager is authorized to execute all documents required to carry out and implement the Project as reviewed and approved by Agency's legal counsel, including, but not limited to, a Notice of Determination.

Appendix G

Responsiveness Summary

Department of Toxic Substances Control

ın C. Lloyd, Ph.D.
gency Secretary
Cal/EPA

1011 North Grandview Avenue
Glendale, California 91201

Arnold Schwarzenegger
Governor

November 28, 2005

RESPONSIVENESS SUMMARY

Project Title: Castaic Lake Water Agency, Groundwater Containment and Restoration Project

Project Location: The Project is located in the City of Santa Clarita, California

Contact Person: Jose Diaz (818) 551-2171

In compliance with Health and Safety Code section 25356.1(e) (1) a public comment period was held from August 22nd to September 23rd 2005, and in compliance with the California Environmental Quality Act (CEQA), a public comment period was held from August 5th to September 8th 2005. The purpose of the comment period was to provide the public with an opportunity to review and comment on the activities described in the draft Interim Remedial Action Plan (draft IRAP) proposed by the Department of Toxic Substances Control (DTSC) and Mitigated Negative Declaration proposed by the Castaic Lake Water Agency (CLWA) for the subject project. A public meeting was held on September 7, 2005.

Written and verbal comments were received on the CEQA draft Mitigated Negative Declaration and the draft IRAP, during their respective comment periods. Transcripts from the September 7, 2005 public meeting and DTSC responses to written comments are included in Appendices F and G of the final IRAP.

List of Revisions: DTSC has fully reviewed and evaluated the comments received. DTSC revised the following portions of the IRAP:

Revision 1: Section 6.1.5 of the draft IRAP has been revised to indicate that approval of modifications to the existing water supply system is not within DTSC's jurisdiction.

(This Page Intentionally Blank)

**COMMENTS ON THE DRAFT INTERIM REMEDIAL ACTION PLAN (IRAP)
PUBLIC COMMENT PERIOD: AUGUST 22ND TO SEPTEMBER 23RD, 2005
PUBLIC MEETING: SEPTEMBER 7TH, 2005**

Comment from Mr. and Mrs. Gerald Hall, 27446 Arriola Avenue, Saugus, CA 91350

Comment 1a: Total destruction of perchlorate by biological means strikes us the best method.

a. Why would this method be "more difficult to reliably operate than ion exchange systems?
b. What "further treatment prior to pumping it into the distribution system" would be required?
c. Why is this a problem?

Response: In pilot studies of the fluidized bed reactor (FBR) and fixed bed reactor (FXB) biological treatment systems, perchlorate removal to concentrations less than the laboratory detection limit was achieved in the FXB system using only organisms indigenous to the Saugus Formation. The FBR system did not achieve perchlorate removal to concentrations below the detection limit over a period greater than eight days. Although the present worth costs of ion exchange treatment systems and biological treatment systems are very similar, the ion exchange alternative ranks very high in the implementability criteria. Ion exchange systems represent a physiochemical process that can be controlled and monitored more easily than biological treatment systems. In general, biological water treatment systems are more subject to upset than are physiochemical treatment systems. Initial startup or restoring a biological treatment system following an upset event requires significant operator attention. In addition, the California Department of Health Services (DHS) has only issued conditional acceptance of biological treatment using FBR to remove perchlorate from drinking water at another site while ion exchange treatment is a DHS-approved technology for drinking water applications.

Following treatment by ion exchange, the groundwater would be disinfected. If biological treatment were selected, the groundwater would require filtration and disinfection prior to pumping into the distribution system. This filtration step could be provided at CLWA's existing Rio Vista Water Treatment Plant, but treating groundwater would displace capacity needed for treatment of imported surface water. It would also add an ongoing operational cost to the biological treatment alternative.

Comment 1b: In the ion exchange process no mention is made of what happens to the perchlorate exchanged.

a. Where would the exchanged perchlorate go?
b. What will happen to it?

Response: In the ion exchange process, perchlorate is captured by the resin within the exchange vessels. The spent resin will be managed as a solid waste and will require periodic removal, replacement, and offsite incineration. During incineration, the resin and the perchlorate ion are completely destroyed, eliminating the possibility of generating a new waste stream.

Comment 1c: What is your rationale for choosing non-destructional exchange over destruction?

We feel that money (if this is a consideration) should be no object when considering public safety – Sue Whittaker, the Defense Dept. and Federal government if necessary – But do it right the first time!!

Response: The "non-destructional" treatment (ion exchange) method can be operated and monitored more easily than the "destructional" (biological) method. As mentioned above, the present worth costs to implement and maintain are similar. Also, the perchlorate captured by the ion exchange resin will be destroyed via incineration at an offsite location. Finally, the ion exchange treatment is expected to be more readily approved by DHS and accepted by the community.

Comment from Ms. Stephanie Young, 25552 Penbrook Place, Santa Clarita, CA 91350

Comment 2a: "Having read the summary, it seems that the chosen option #2 is the best option. Please proceed".

Response: Thank you for your comment.

Comment from Mr. Tom Carver, 27845 Crookshank Drive, Saugus, CA 91350

Comment 3a: We appreciate receiving information concerning toxic substances. In the future, would you mail this information to Tom Carver at the same address, 27845 Crookshank Drive, Saugus, CA 91350. Toby Carver is our son and previous homeowner. Thanks.

Response: Thank you for your interest in the project, your name has been added to our mailing list.

Comment from Dr. Gary Ordog, (1) Santa Clarita Water Conditioning, (2) Medical Toxicology, 23206 Lyons Avenue #103, Santa Clarita, CA 91321

Comment 4a: High volume water purification may not continuously remove all the perchlorate and associated contaminants from our homes.

I recommend a whole house water purification installed by Santa Clarita Water Conditioning, Inc.

It has 5 stages including hepa, antimicrobial, hydromagnetic, granular activated carbon, quartz, and reverse osmosis.

As most toxics are absorbed from non-drinking water exposure in the house, whole house filtration is required. I believe our system is the best commercially available for this purpose.

I believe your agency should agree, and endorse such a system.

<u>Response</u>: *The mission of the Department of Toxic Substances Control (DTSC) is to protect human health and the environment by cleaning sites where releases of hazardous substances have occurred or will potentially occur. The individually installed treatment systems cannot be monitored by DTSC and therefore cannot replace the treatment method proposed in the IRAP.*

Comment from Ms. Valerie Thomas, P.O. Box 220907, Newhall, CA 91322

<u>Comment 5a</u>: It's been a long battle to get to this point. Please emphasize even more strongly how the community will be as well protected under DTSC procedures as we would be under a full EIR. Please also discuss more about the choice of alternative 2 – that it has been employed successfully in other communities and that the other alternatives would require more time to get Health Dept. approval and make Santa Clarita, in effect, a guinea pig.

Thank you for your patience and hard work on our behalf.

<u>Response</u>: *The Castaic Lake Water Agency (CLWA) prepared an Initial Study for the proposed containment and restoration plan as required by the California Environmental Quality Act (CEQA) and determined that any potential impacts associated with implementing the proposed containment and restoration can and will be readily mitigated. The proposed mitigation measures are described in the Draft Mitigated Negative Declaration. On this basis, the impact of this project is not of the magnitude that requires preparation of an Environmental Impact Report (EIR) under CEQA. In summary, the project is not expected to create any unmitigated adverse ecological or human health impacts; to the contrary, it is expected to prevent a plume of perchlorate in groundwater from contaminating other water supplies in the area and posing unacceptable risks to human and/or ecological receptors. CLWA is the lead agency for the CEQA process and its Board of Directors will be responsible for certifying the CEQA documents.*

Ion exchange treatment systems are currently being used to remove perchlorate from the water supply in several California communities, including: the West Valley Water

Company in West San Bernardino, the Lincoln Avenue Water Company in Pasadena, the City of Morgan Hill, the San Gabriel Water Company B-6 Well in Baldwin Park, the Fontana Water Company in Fontana and the City of Riverside. The DHS has issued permits to operate these ion exchange systems and the operating data indicate ion exchange is successfully removing perchlorate. In contrast, biological treatment has been used in fewer locations for removal of perchlorate from the water supply, and there is less regulatory and community acceptance of this type of water treatment system. Although evaluated as a technology, membrane filtration has not yet been tested at a full-scale perchlorate removal water treatment system. For all of these reasons, the ion exchange perchlorate removal process was considered the most likely to promptly gain regulatory approval and public acceptance, as well as the treatment method that would most reliably and cost-effectively remove perchlorate.

Comment from Ed and Joan Dunn, 15414 Rhododendron Drive, Canyon Country, CA 91387

(Letter dated September 22, 2005).

Comment 6a: We oppose the cleanup plan as proposed. In the early stages, a totally different and apparently more economical clean-up plan was proposed. That plan would utilize a central location to manifold the contaminated wells, including Newhall County Water District (NCWD) well #11, for treatment at one nearby location. The location and project would probably only require a negative declaration. The output of that treatment facility would be connected to near-by existing mains. Evidently, that plan was scrapped because it would not bring the output water to Castaic Lake Water Agency (CLWA) for their total control. That plan appears to be much more economical than alternative #2 that apparently has been amended to include piping the water a long distance to CLWA's pumping station facility. It is to be noted that alternative #2 suddenly left NCWD's well #11 out completely. We believe NCWD's well #11 can effectively be treated at the wellhead. NCWD's well #11 is located in close proximity to NCWD's wells #12 and #10. There is sufficient NCWD property available for a treatment facility at those well locations. The output of the treatment facility would discharge into NCWD's wells #12 and #10. There is sufficient NCWD property available for a treatment facility at those well locations. The output of the treatment facility would discharge into NCWD's large main pipe in the nearby San Fernando Road. All three NCWD's wells #11, #12, and #10 are already connected to NCWD's main. If the Department of Health Services desired, the output of the treatment facility could be discharged into the adjacent South Fork of the Santa Clara River. In addition, due to NCWD's location south-west of the plume's travel, we believe that the pollution level and length of time to clear the pollution will be greatly reduced.

Response: During the development of alternatives, well-head treatment for NCWD's Well NC-11 was considered. Subsequently, the groundwater modeling performed by CH2MHill indicated that continual pumping of groundwater at Saugus Wells 1 and 2 should limit the flow of groundwater containing perchlorate toward the NCWD *production wells NC-11, NC-12 and NC-13. This predicted result will be confirmed through additional groundwater monitoring and evaluation of the resulting data once Saugus Wells 1 and 2 are restored to service. The potential for future installation of well-head treatment for NCWD Well NC-11 has not been ruled out. Given that the groundwater is currently used for water supply purposes, and its continued use is an important component of the water supply plans for Santa Clarita Valley, it is unlikely that the treated groundwater would be discharged to the river system.*

Comment 6b: We suggest that an unbiased, independent engineering firm study all honest options for this cleanup project. We do not have confidence in engineering data or reports that come from Kennedy/Jenks Engineering Company. In our opinion, Kennedy/Jenks tailors their reports to meet the desires of CLWA. CLWA by their actions and statements indicate they wish to control all water resources in the Santa Clarita Valley. We believe that this is what is driving the design of this cleanup.

Response: DTSC does not participate in consultant selection for parties who have entered into a Voluntary Cleanup Agreement. Kennedy/Jenks is CLWA's engineering consultant and the IRAP meets DTSC's requirements.

Comment 6c: It is interesting to note that CLWA indicates that multiple new wells will be drilled far west of the Saugus wells # 1 and # 2. The new location is in the Valencia Water Company's (VWC) service territory adjacent to or at the large, new "Newhall Ranch Project". It is our understanding that VWC had already received approval from the Public Utilities Commission (PUC) to install these wells for the Newhall Ranch Project. It is also our understanding that the location and the expense of these wells is for the purpose of serving the Newhall Ranch Project and was to be paid for by VWC. We question how the drilling of these new wells becomes part of the perchlorate cleanup. We suggest any new wells that are to replace poisoned wells be in the proximity of the area that the poisoned wells were serving.

Response: Installation of replacement water supply wells is not within the scope of the IRAP for this project. Under the proposed containment plan, Saugus Wells 1 and 2 will be pumped continually, but at rates less than their pumping capacities, potentially leaving a groundwater supply gap during drought or other water supply shortage. Replacement Saugus Formation wells are proposed to be consistent with the water supply plans for the Santa Clarita Valley and to fully restore the lost Saugus Formation production capacity. The locations of the two proposed replacement water supply wells were selected based upon hydrogeologic evaluation and with the interest in locating the wells outside of the area of potential impact by perchlorate.

Comment 6d: The plan commandeers a valuable potable main water main for the purpose of transporting polluted water to CLWA's facility. We do not understand how CLWA can legally transport polluted water through a pipe that is not purple in color, as required by law. To compensate for the loss of the potable water main, CLWA is planning to install additional larger potable pipes. We also believe that installing new potable water pipes, and transporting polluted water through previous potable water pipes located in the streets etc., require a complete EIR.

<u>Response</u>: Approval of proposed modifications to the existing water distribution systems does not fall within DTSC's jurisdiction. CLWA is the lead agency for CEQA and your comment should be forwarded to them.

<u>Comment 6e</u>: We oppose a negative declaration for this disruptive project of piping great distances to transport water to CLWA's pumping station facility and that a complete EIR should be required. We suggest DTSC reject the present plan by CWLA.

Please include and enter into the record, our letter of September 22, 2005 addressed to Ms. Sara Amir on this same subject.

<u>Response</u>: CLWA is the lead agency for CEQA issues. Comments regarding the Mitigated Negative Declaration should be forwarded to CLWA.

Letter dated September 23, 2005

<u>Comment 6f</u>: On September 7, 2005, in a community meeting at Santa Clarita, we voiced our concerns about how we believed this plan was a "done deal". (We videotape all Castaic Lake Water Agency (CLWA) meetings, including committee meetings). To back up our statements we are supplying a tape of two meetings of CLWA.

After a presentation of the remedy piping system on May 26, 2005, at a planning and engineering committee meeting, Mr. Masnada, General Manager of CLWA, says, "The other aspect is, we're proceeding ahead with the containment and treatment regardless of what happens…".

At the second meeting on June 8, 2005, a regular meeting of CLWA, after the same presentation, Mr. Masnada says "As I recall, there's 23 and a half million in the budget for this…"! "We are moving ahead right now to implement the remedy...".

Both of these meetings occurred before your meeting September 7th 2005, where you state that it is not a "done deal". We understand that you believed that it was not a "done deal", but you were unaware of CLWA's position.

<u>Response</u>: No decisions were made by DTSC prior to the comment period which ended on September 23, 2005.

<u>Comment 6g</u>: We have a concern about Newhall County Water District's (NCWD) well #11. NCWD's well has been out of service since 1997 and there seems to be little or no activity to solve the loss of the water problem of this well. Well #11 has sufficient NCWD property nearby to install wellhead treatment equipment. There also is a large NCWD water pipe main connected to well #11 that could accommodate the output of the treatment system. Furthermore, well #11 appears to be out of the mainstream area of the contaminant plume. We believe that well #11 would not require treatment for a long period of time, thus reducing the total cost of clean-up. We also believe the output of the treatment system, if desired, could be varied by the hydrogeologist as desired.

We believe CLWA is intentionally ignoring NCWD's well #11 with the intent to have the well destroyed and/or get complete control of the well. We do not know of any study, such as test wells around well #11, to check for perchlorate flow or any engineering data showing restoration of well #11.

<u>Response</u>: Please see the response to Comment 6a. Whittaker has installed several groundwater monitoring wells upgradient (east) of Well NC-11. NCWD's recent request for additional investigation of groundwater in this area is being currently discussed with Whittaker and DTSC.

<u>Comment 6h</u>: We do not have confidence in engineering data or reports that come from the Kennedy-Jenks Engineering Company. It is our opinion, Kennedy/Jenks tailors their reports to meet the desires of CLWA. CLWA has made it clear they desire to get control of all water in our community.

<u>Response</u>: See response to Comment 6b.

<u>Comment 6i</u>: Please enter this writing and tape as additional comments to the Interim Remedial Action Plan.

<u>Response:</u> The response to comments will be included in an appendix of the IRAP.

Comment from Ms. Pat Saletore, Santa Clarita Organization for Planning the Environment, P. O. Box 1182, Canyon Country, CA 91386

<u>Comment 7a</u>: We believe that a mitigated negative declaration is not a sufficient document for the preferred alternative project. Such a document might be considered sufficient for the alternatives that propose clean up only at the well head, but the extensive piping and centralization of water supply by the preferred alternative are not adequately addressed by a mitigated negative declaration. Should this alternative continue to be considered, we request that the DTCS address the following issues in a full or focused environmental impact report:

1. There will be substantial impacts to the Santa Clara River from the piping. Impacts to the river and its habitat were not addressed. These should be fully mitigated by restoration or public acquisition of additional wetland areas.

2. The pipes to pump and distribute remediated water are over-sized for the clean-up needs and therefore will accommodate new growth. This should be addressed as a growth inducing impact.

Response: CLWA is the lead agency on the CEQA documents. Comments on the CEQA documents should be directed to CLWA.

Comment 7b: Further, we concur with the Sierra Club comments and believe the containment plan is deficient in the following areas. These areas should be redressed before the plan is approved.

1. There are additional contaminants in the pollution plume that will not be removed or treated by the proposed plan. How will these pollutants including TCE, PCE and NDMA be removed? Some of these are known carcinogens.

2. There is no proposal to remove any pollution at the source, yet there are pollution hot spots registering as high as 58,000 ppb on the site. Without a source/site clean-up plan, large quantities of pollution will continue to emanate from the site. We cannot understand why ONLY well head treatment is being proposed and not source clean-up. This may indicate that the water agencies feel not reducing supply is far more important than solving the problem at the source. Failure to address source clean-up is an area in which we feel that policy may be driven by developer water supply concerns rather than good long-term public policy that protects the community's health.

3. The containment wells may very well not work. The whole proposal is based on existing wells so that the water districts can continue to pump. The hydrology is simulated and may not be accurate when the plan is implemented. The CLWA proposal utilizes existing wells that may not capture the plume as planned. What alternative is proposed to address a deficiency of this containment plan?

4. The proposal to pump everything into CLWA for clean-up will give CLWA a monopoly over water supply in the Santa Clarita Valley. This will also centralize water supply in the Santa Clarita Valley. Upon review of the recent energy crisis and the solutions now being suggested to the energy problem, we believe it is best to have decentralized sources that can be coordinated, rather than one centralized source. Decentralization will ensure efficiency, equity, and public oversight for water supply in an area where there is great concern about the adequacy of this public resource. It will also reduce disruption in the case of an earthquake because supply will continue to be available from multiple sources.

Response: 1. In addition to perchlorate, other contaminants, including volatile organic compounds (VOCs) are present in groundwater in some areas within the Whittaker-Bermite site. Water quality in all groundwater production wells is routinely monitored. The available data from Saugus Wells 1 and 2 do not indicate that contaminants other than perchlorate are present at concentrations requiring treatment. As required by DHS, the proposed plan includes the concept of "sentinel" groundwater monitoring wells to be installed upgradient of Saugus Wells 1 and 2. These sentinel wells will be monitored on a regular basis to evaluate the concentrations of perchlorate and other potential *contaminants in groundwater flowing toward the production wells. If contaminants other than perchlorate are found at concentrations of concern in samples from these sentinel wells, the groundwater treatment system can be modified to add the necessary components to treat the additional contaminants.*

2. Addressing the sources of contamination is critical, however, investigation and cleanup of the onsite source areas is being conducted by Whittaker under the oversight of DTSC. The groundwater containment plan proposed by CLWA will serve as a component of the overall remedy, but is not the complete remedy. CLWA's project provides containment for the groundwater contamination that has already migrated away from the Whittaker-Bermite site.

3. & 4. The proposed pumping plan will capture Saugus Formation groundwater containing perchlorate. Following start up of pumping from the Saugus Wells 1 and 2, groundwater monitoring will be performed to evaluate the effectiveness of capture. Depending upon the resulting data and its evaluation, it is possible that the pumping rates for Wells Saugus 1 and 2 will be modified to achieve the desired containment of groundwater. The decision to decentralize the water supply in the Santa Clarita Valley is not under DTSC's jurisdiction. Please contact CLWA directly with these concerns.

Comment from Connie Worden-Roberts, Chairman, CAG, 25709 Rye Canyon Road, Suite 105 Valencia, CA, 91355

<u>Comment 8a</u>: While it is my intention to write a more substantial response as the Chairperson of the Citizens Advisory Group, circumstances have precluded my plans. However, I would be remiss not to sincerely thank the Department of Toxic Substances Control for the professionalism and thoroughness you have evidenced throughout the past years. You have been responsive to CAG's inquiries, attentive to the magnitude of toxics present in the 996 acre site, and have worked closely with the water agencies to assure the delivery of safe water to the citizens as well as developing a plan for complete clean-up of the entire area. Your work with the Army Corps of Engineers in mapping the entire water system is commendable. Your geologic and environmental studies added greatly in obtaining a comprehensive understanding of the whole area.

On behalf of the CAG, I want to thank you for working with the Water Agencies to assure that potable water would be delivered to the citizens of Santa Clarita. (That is the reason I originally petitioned the State to permit the formation of the CAG.) It is also the reason I am sending you an article from the Daily News which states that the groundwater plan is inadequate. While groups may decry the plan, in the main they have not been in attendance of Multi-jurisdictional or Citizen Advisory Meeting over the years, and assume things which are not true.

I, as well as other sincerely concerned citizens, look forward to continuing to work with DTSC until the entire project is cleansed of any and all pollutants. We are grateful the owners of Bermite Whittaker Corporation have stepped up to their responsibility to pay for the clean-up, that I recognize is costly. Returning this vital portion of the Valley to a thoroughly clean and productive state is paramount.

Thank you for all of your assistance, may we all be proud of the progress on the clean-up!

<u>Response</u>: *Thank you for your comments and especially, for your continued participation in the Citizens Advisory Group.*

Comment from Ms. Rachel Myers, Conservation Coordinator, Sierra Club, 3435 Wilshire Blvd, Suite 320, Los Angeles, CA 90010-1904

<u>Comment 9a</u>: The Sierra Club has consistently commented on the ammonium perchlorate pollution plume in the Santa Clarita Valley for many years and before many agencies. These include comments on project approvals granted before remediation facilities are operating, inclusion of polluted water in water plans as though it were available and concerns regarding continued spread of the plume. We litigated the issue of inclusion of the polluted water in CLWA's Urban Water Management plan. That Plan was set aside by the 2nd Appellate Court in a published decision last November over these concerns.

We would like to preface this comment letter with a short paragraph addressing the water agencies' (and others') accusations that the environmental community is "just trying to stop growth". That is NOT the basis of our concern, although we realize that ultimately, if the pollution problem is not solved, that may indeed be a needed short term solution. Instead, our goal is to protect public health, especially the health of children. The Sierra Club has been active in many pollution issues on a national level including lead paint, arsenic, and other pollutants that affect children particularly, as well as air pollution contaminants that cause asthma, again affecting children in particular. We therefore request that you ignore and dismiss any such disingenuous accusations and accept these comments as they are intended to be, i.e., legitimate concerns for public health in the Santa Clarita Valley.

<u>Comment 9b</u>: We believe that the containment plan is deficient in the following areas. These areas should be redressed before the plan is approved.

1. There are additional contaminants in the pollution plume that will not be removed or treated by the proposed plan. How will these pollutants, including TCE, PCE and NDMA be removed? Some of these are known carcinogens.
2. There is no proposal to remove any pollution at the source, yet there are pollution hot spots registering as high as 58,000 ppb on the site. Without a source/site clean-up plan, large quantities of pollution will continue to emanate from the site. We cannot understand why ONLY well head treatment is being proposed and not source clean-up. This indicates to us that the water agencies feel not reducing supply is far more important than solving the problem. Failure to address source

clean-up is the area in which we feel that policy may be driven by developer water supply concerns rather than good long-term public policy that protects the community's health.

3. The containment wells may very well not work. The whole proposal is based on existing wells so that the water districts can continue to pump. The hydrology is simulated and may not be accurate when the plan is implemented. The consultants working on the simulation are all controlled through Valencia Water Co., wholly owned by Lennar/Newhall Corporation. This may create a conflict in goals due to Valencia Water Co.'s parent company development plans.
4. This plan is not a proposal like the one in the San Gabriel Valley where granite or non-porous material occurs on each side of the river, funneling the contaminated water into a particular area. That plan strategically placed NEW wells to catch the contamination. The CLWA proposal utilizes existing wells that somehow remarkably occur in exactly the right place to capture the pollution plume. What alternative is proposed to address the failure of this containment plan?
5. The pipes to pump and distribute remediated water are over-sized for the clean-up needs and therefore will accommodate new growth. This should be addressed as a growth inducing impact.
6. There will be substantial impacts to the Santa Clara River from the piping. Impacts to the river and its habitat were not addressed. These should be mitigated.

__Response__: 1. Please see response to comment 7b, 1 above.

2. Please see response to comment 7b, 2 above.

3. Please see response to comments 7b, 3 and 4 above.

4. Please see response to comments 7b, 3 and 4 above. Also note that the final cleanup strategy has not been completed for the Whittaker-Bermite site. The proposed pumping of groundwater from Saugus Wells 1 and 2 is an interim measure relative to measures that will be required to address all of the contamination originating at the Whittaker-Bermite site. Pumping from Saugus Wells 1 and 2 is proposed at this time to limit potential future impacts to the Valley's groundwater resources.

5. Please see the response to comment 7a. above.

6. Please see the response to comment 7a. above.

__Comment 9c__: Further, the proposal to pump everything into CLWA for clean-up will give CLWA a monopoly over water supply in the Santa Clarita Valley. The Sierra Club wishes to express its concern regarding this idea. Looking at what occurred in the energy recent crisis and the solutions now being suggested to the energy problem, we believe it is best to have decentralized sources that can be coordinated. That will ensure efficiency, equity, and public oversight for water supply in an area where there is great concern about the adequacy of this public resource.

Response: Please see the response to comments 7b, 3 and 4.

Comment from Ms. Cam Noltemeyer, 25936 Sardinia Court, Valencia, CA 91355

Comment 10a: Why are only the two production wells Saugus 1 and Saugus 2 addressed in this IRAP?

Response: The IRAP addresses the Saugus Formation production wells that have been impacted by perchlorate. Based on the results of the alluvium and Saugus Formation investigation and groundwater modeling performed by the U.S. Army Corp of Engineers, pumping of these two wells will contribute to containing the plume of perchlorate-impacted groundwater.

Comment 10b: Why aren't the contaminated wells in the Newhall County Water District and Valencia Water Company addressed in this IRAP?

Response: As discussed above in the response for Comment 10a, the groundwater modeling performed to date indicates that operation of Wells Saugus 1 and 2 should limit the flow of groundwater containing perchlorate toward NCWD's Well NC-11. If future groundwater monitoring results indicate that NCWD's production wells are threatened, installation of well-head treatment for these wells will be considered.

Comment 10c: Why hasn't there been any public meeting regarding the Valencia Water Company treatment of contaminated water that it intends to dump into the water supply? Their treatment systems are already operating.

Response: DHS is the agency providing oversight and approval of the ion exchange perchlorate removal system for Well Q-2. Please contact this agency with your questions or concerns.

Comment 10d: Why are all the environmental impact reports for the Whittaker-Bermite project being done in a piece meal manner?

Response: There are numerous areas at the Whittaker-Bermite site where chemical releases have impacted soil and groundwater. For ease of management, the site has been administratively divided into Operable Units and the response actions are frequently different and scheduled separately for these Operable Units. Areas where the chemical impact has been characterized can be moved more quickly forward into the remediation phase, while other areas are still being characterized. It does mean that remediation for some areas proceeds faster than others, but the benefits of initiating remediation more rapidly where possible outweigh the drawbacks of waiting for characterization and remediation planning to be complete for the entire site. The proposed pumping of Saugus

Wells 1 and 2 is one of those actions that can be implemented now, without waiting for completion of other activities at the Whittaker-Bermite site.

Comment 10e: Alternative 2, aboveground ion exchange system being used to remove perchlorate from the groundwater pumped from the Saugus 1 and 2 wells will exchange the perchlorate for chloride. How is the chloride removed from the water? How safe is chloride in drinking water?

Response: DHS regulates chlorides in drinking water as a secondary drinking water standard. The long term maximum contaminant level for chloride established by DHS for community water supplies is 250 parts per million (ppm). The chloride level in water produced by the Saugus Formation is between 20 and 40 ppm, well below the secondary drinking water standard. The treatment process is estimated to add less than 1 ppm of chloride to the treated water. Therefore, the concentration of chloride introduced by ion exchange treatment is not expected to be a water quality concern and removal of chlorides from the water is not planned.

Comment 10f: Why isn't the water treated with the ion exchange system returned to the ground water rather than being pumped into our drinking water?

Response: The Saugus Wells 1 and 2 were used for water supply prior to the discovery of perchlorate in samples from these wells. This water is necessary for CLWA to restore the groundwater production capacity that was lost due to perchlorate contamination. CLWA and the other purveyors are responsible for maintaining and providing a safe, sufficient and reliable water supply in the Valley. CLWA will routinely test the water under DHS oversight to ensure that is safe for distribution and consumption.

Comment 10g: Please provide a list of other communities where the ion exchange systems have been used to put perchlorate-contaminated water directly back into the drinking water.

Response: Please see the response to question 5a.

Comment 10h: The ion exchange systems only addressed perchlorate. How are the other two primaries COIs in the groundwater, trichloroethylene (TCE), and tetrachloroethylene (PCE) being treated before putting this water directly into the water supply?

Response: Please see the response to question 7b, 1.

Comment 10i: How are all the other trace amounts of COIs, potential COPCs, VOCs, SVOCs, nitroaromatics and nitroamines (explosive compounds) and nitrosamines being treated before putting this water directly into the water supply?

Response: Please see the response to question 7b, 1.

Comment 10j: Will the pumping of Saugus 1 and Saugus 2 wells contain the toxic plume in the deep Saugus Formation or will it cause the plume to spread?

Response: The groundwater modeling performed to date indicates that the proposed pumping of Saugus Wells 1 and 2 will serve to contain the plume of perchlorate in the Saugus Formation. The modeling results will be re-evaluated using monitoring data obtained after the two production wells are returned to service. As necessary to provide adequate containment of the perchlorate in the Saugus Formation, the proposed groundwater pumping rate may be modified. It is not expected that pumping these wells will cause the plume to spread, and instead the pumping will curtail spreading of the plume.

Comment 10k: It appears that the only reason for this Interim Remedial Action Plan that only covers two of the contaminated wells is the desperate need for the Castaic Lake Water Agency to include this contaminated water as available in their 2005 Urban Water Management Plan. Newhall Land needs proof of water availability to get approval of their 2,200 home West Creek subdivision slated for 990 acres in unincorporated Northern Valencia. Water to be provided by Valencia Water Company that is owned by Newhall Land. Newhall Land also needs water for their 1,089 home Riverpark subdivision. Water to be provided by the Santa Clarita Water Company that is owned by the Castaic Lake Water Agency. It appears that the Castaic Lake Water Agency and the DTSC are more interested in accommodating the greed of developers than protecting the water supply that the public has to drink. Is the purpose of this plan to provide quantity of water without regard to the quality of the water?

Response: The purpose of this plan is to provide containment of the impacted groundwater and to restore the groundwater production capacity that was lost due to the presence of perchlorate. Use of groundwater in the Santa Clarita Valley is an important component of the overall reliability of the water supply, especially during drought conditions or other circumstances where the delivery of imported surface water may be reduced. Prior to the discovery of perchlorate, groundwater from the Saugus Wells 1 and 2 was used for water supply; other than the presence of perchlorate (which will be removed through the proposed ion exchange process), the quality of the Saugus Formation water is unchanged.

Comment 10l: I strongly object to having contaminated water from Saugus 1 and Saugus 2 Wells are any other contaminated well being placed directly back into our drinking water supply. If the Valencia Water Company Well V-157 and Newhall County Water District Well NC-11 in the Saugus Formation can be destroyed and replaced with new wells with clean water why can't Santa Clarita Water Company do the same?

Response: Please see response to comment 10f.

Comment from Mr. Joe Weiss, 20305 Gray Lane, Santa Clarita, CA 91351

Comment 1: Excellent explanation – although quite technical. Go for it!

Response: Thank you for your support.

Valencia Water Company Letter to Impact Sciences, March 8, 2006

Valencia Water Company

24631 Avenue Rockefeller • P.O. BOX 5904 • Valencia, CA 91385-5904
(661) 294-0828 • Fax (661) 294-3806

March 8, 2006

Impact Sciences
Mr. Tom Worthington
803 Camarillo Springs Road
Suite A
Camarillo, CA 93012

Dear Mr. Worthington,

This letter has been prepared in response to a request from Impact Sciences to provide information about the quality of groundwater to be provided by the Valencia Water Company (Valencia) to serve the Landmark Village Community of Newhall Ranch. Valencia is the retail water purveyor identified to serve this community and has prepared the following responses:

Question 1: What information is available to show the groundwater sources identified for the Landmark Village Community meet all applicable drinking water standards?

Potable water demands for the Landmark Village Community will be met by using groundwater produced from the Alluvial aquifer from newly constructed replacement wells approved and permitted by the California Department of Health Services (DHS). These wells replaced older wells used for irrigation that are no longer active having been permanently closed as directed by DHS. For many years, the Alluvial aquifer has been a significant source of potable water supply for the Santa Clarita Valley and Valencia has extensive experience operating numerous wells in the Alluvial aquifer that produce groundwater that meet all state and federal drinking water standards.

Valencia received an Amended Water Supply Permit 1910240PA-003 (see **Attachment A**) in August 2004 from DHS for approval to construct and place into operation as active sources of domestic water supply four groundwater wells designated as E14, E15, E16, and E17. The wells have been installed and Valencia has completed a round of sampling in accordance with the California Safe Drinking Water Act (CSDWA). The results were provided to DHS and were shown to be in compliance with all drinking water standards under California Code of Regulations Title 22, Division 4, Chapter 15. The water quality results from the four E wells are similar to existing Alluvial wells operated by Valencia.

Water quality tests completed for the E wells did not detect levels of any volatile organic chemicals. The inorganic tests found fluoride (0.83 mg/L – 0.9 mg/L) and nitrate (as NO_3) (11 mg/L – 16.8 mg/L) at typical background levels normally found in the Alluvial aquifer. All other inorganic results were non-detect. The general mineral results were also consistent with water quality found in other Alluvial wells operated by Valencia. See **Attachment B** for a complete list of constituents sampled, results, and corresponding Maximum Contaminant Levels (MCL). The test results confirm that the four Valencia E wells are in compliance with all applicable drinking water standards.

Valencia has completed construction of Well E15 and received approval from DHS to place the well in service. The three other wells will be phased into Valencia's distribution system when needed as a source of supply. Prior to placing E14, E16 and E17 into service, Valencia is required to collect an additional round of Title 22 constituents and required bacteriological samples and submit the results to DHS for review and approval. The second round of Title 22 sample results for E15 is provided in **Attachment C**. The test results confirm that Well E15 is in compliance with all applicable drinking water standards.

Question 2: DHS requires that all groundwater be disinfected. Valencia uses calcium hypochlorite to disinfect groundwater at the well head. What is the estimated increase in concentration of chlorides that results from this treatment process?

Valencia disinfects its groundwater supply with calcium hypochlorite (65% available chlorine) to an average dosage of not more than 0.5 mg/L. As the oxidation-reduction reaction occurs with the chlorine residual in the distribution system, chlorine will eventually convert to chloride. It is difficult to determine where and when in the system this conversion occurs. However, for purposes of this discussion, it is assumed that all the available chlorine added to Valencia's groundwater converts to chloride and ends up in the waste stream. Therefore, the added chloride would not be more than 0.5 mg/L.

Water quality tests performed on the E wells before disinfection show a range of chloride levels of 75 mg/l to 89 mg/L. These background levels are far below the secondary MCL for chloride of 250 mg/L. Valencia proposes to add up to 0.5 mg/L of calcium hypochlorite to the groundwater as a primary disinfectant. Following disinfection, chloride concentrations are expected to increase up to 0.5 mg/l or an increase of approximately 0.6% over background levels found in the Alluvial aquifer. Therefore, Valencia's use of calcium hypochlorite to disinfect groundwater would slightly increase the level of chloride found in groundwater and would still be far below the secondary MCL for chloride of 250 mg/L.

Tom, please call me if you have any questions.

Sincerely,

Robert J. DiPrimio

STATE OF CALIFORNIA

AMENDMENT TO THE

DOMESTIC WATER SUPPLY PERMIT ISSUED TO
the Valencia Water Company
Public Water System - 1910240

ORIGINAL PERMIT: ***65-139***	DATE OF ISSUE: ***10/29/65***
PERMIT AMENDMENT: ***Not Numbered***	EFFECTIVE DATE: ***02/20/79***
PERMIT AMENDMENT: ***Not Numbered***	EFFECTIVE DATE: ***01/15/82***
PERMIT AMENDMENT: ***Not Numbered***	EFFECTIVE DATE: ***02/21/86***
PERMIT AMENDMENT: ***04-07-99PA-000***	EFFECTIVE DATE: ***09/24/99***
PERMIT AMENDMENT: ***04-15-00PA-000***	EFFECTIVE DATE: **08/30/00**
PERMIT AMENDMENT: ***1910240PA-001***	EFFECTIVE DATE: ***10/06/03***
PERMIT AMENDMENT: ***1910240PA-002***	EFFECTIVE DATE: ***03/11/04***
PERMIT AMENDMENT: ***1910240PA-003***	EFFECTIVE DATE: ***08/30/04***

WHEREAS:

I. The ***Valencia Water Company*** (hereinafter, the Company) submitted two applications to the California Department of Health Services (hereinafter, the Department) on ***February 28, 2003*** and ***May 25, 2004*** for an amendment to the Domestic Water Supply Permit issued to the ***Company*** on ***October 29, 1965.***

II. The purpose of the amendment, as stated in the application, is to allow the ***Company*** to make the following modifications to the public water system:

Construct five (5) replacement groundwater wells (U6, E14, E15, E16, and E17).

III. The ***Company*** has submitted all of the supporting information required to evaluate the application.

IV. The Department has evaluated the application and the supporting material and has determined that the proposed modifications comply with all applicable State drinking water requirements.

THEREFORE:

I. The Department hereby approves the application submitted by the ***Company*** for a permit amendment. The Domestic Water Supply Permit issued to the ***Company*** on ***October 26, 1965*** is hereby amended as follows:

The Company may place into operation Wells U6, E14, E15, E16, and E17 as active sources of domestic water supply.

II. This permit amendment is subject to the following conditions:

1. The Company shall comply with all state laws applicable to public water systems and any regulations, standards, or orders adopted thereunder.

2. All water supplied by the Company for domestic purposes shall meet all Maximum Contaminant Levels (MCLs) established by the State Department of Health Services. If the water quality does not comply with the California Drinking Water Standards, treatment shall be provided to meet standards.

3. The only approved sources of domestic water supply are listed in Tables 1 and 2.

Table 1. Groundwater Sources

Well E17 - Tablet Chlorination	1910240-067	Calcium hypochlorite

5. No changes, additions, or modifications shall be made to the sources or treatment processes outlined in Provisions 3 through 4 unless an amended water permit has first been obtained from the Department.

6. All treatment facilities shall be operated by personnel who have been certified in accordance with the Operator Certification Regulations, California Code of Regulations, Title 22. The treatment facility classifications and minimum grade shift and chief operators are listed in Table 4.

Table 4. Treatment Plant Classifications and Minimum Grade Requirements

Treatment Facility	Treatment Plant Classification	Minimum Shift Operator	Minimum Chief Operator
Well-site Chlorinators	T1/D1	T1/D1	T1/D1

7. The Company shall comply with all state laws applicable to public water systems and any regulations, standards, or orders adopted thereunder.

8. Wells U6, E14, E15, E16, and E17 shall be equipped with inverted, screened air-relief valves and casing vents, check valves, flow meters, and sampling taps. The wells shall be equipped with the necessary appurtenances to provide for continuous chlorination and pump to waste capabilities.

9. Prior to placing Wells U6, E14, E15, E16, and E17 into service, an additional round of Title 22 constituents and bacteriological samples including HPCs shall be collected, analyzed, and submitted to the Department for review and approval.

10. Prior to placing replacement Wells E14, E15, E16, and E17 into service, the Company shall properly destroy Wells E5, E, E2, and E4, respectively, in accordance with the Department of Water Resources Water Well Standards (Chapter II, Part III of Bulletin 74-81 and Part III of Bulletin 74-90) and provide the well destruction reports to this Department.

11. Well U6 shall be monitored quarterly for perchlorate given that it is located relatively close to a known perchlorate contaminant plume.

12. The Company shall sample the water from its sources and have the water analyzed in compliance with Title 22, Division 4, Chapter 15 of the California Code of Regulations. All Chapter 15 monitoring results shall also be submitted to the Department by electronic data transfer (EDT) using the proper PS codes.

13. Well U6 shall be monitored quarterly for nitrate given that the well exceeds 50 percent of the MCL.

This amendment shall be appended to and shall be considered to be an integral part of the Domestic Water Supply Permit issued to the ***Valencia Water Company*** on ***October 29, 1965.***

TECHNICAL MEMORANDUM

LUHDORFF & SCALMANINI CONSULTING ENGINEERS

Evaluation of Groundwater Recharge Methods for the Saugus Formation in the Newhall Ranch Specific Plan Area

Prepared for: Tom Worthington, Impact Sciences

Prepared by: Joseph C. Scalmanini

Date: March 8, 2006

Project Number: 06-1-017

Introduction

Included with the approval of the Newhall Ranch Specific Plan was a condition that "prior to approval of the first subdivision map which permits construction, a report will be provided by the applicant which evaluates methods to recharge the Saugus Aquifer within the Specific Plan, including the identification of appropriate candidate land areas for recharge". In response to that condition, this technical memorandum has been prepared to address recharge of the Saugus Formation in general, as well as within the Specific Plan area. It also addresses groundwater recharge methods as might be applicable to the Saugus Formation, and it provides a summary of artificial recharge feasibility that was previously assessed for the Saugus Formation. Finally, this technical memorandum includes a summary of the recently completed analysis of groundwater basin yield, where that yield is comprised of both the Alluvial and Saugus aquifers, as a basis for concluding about the need for identifying land areas for recharge of the Saugus Formation within the Specific Plan area.

The Saugus Formation

The Saugus Formation is one of two significant aquifers in the Santa Clara River Valley Groundwater Basin, East Subbasin, the other being the less extensive Alluvium that overlies part of the Saugus Formation, generally near the main Santa Clara River and several of its tributaries. The Alluvium extends to a maximum depth of about 200 feet and has been estimated to have a maximum storage capacity of about 240,000 acre-feet. The geologically older Saugus Formation extends several thousand feet in total depth but, for groundwater supply purposes, contains sand and gravel units that represent aquifer materials generally between depths of about 300 and 2,500 feet. The fresh water storage capacity of the Saugus in that depth interval has been estimated to be about 1.65 million acre-feet.

In general, natural groundwater recharge in the Santa Clarita Valley occurs in the eastern portion of the basin, and at the northern and southern limits of the basin. Natural groundwater discharge occurs from the Saugus Formation and the Alluvium in the west-central portion of the basin, in the alluvial valley occupied by the Santa Clara River. Of course, groundwater pumping is also a groundwater discharge mechanism that occurs at distinct locations throughout the basin. Ultimately, however, in the general context of the Specific Plan condition regarding recharge of the Saugus Formation, the occurrence of natural groundwater discharge in the west-central portion of the basin is suggestive of prevailing groundwater conditions that support such a discharge; in other words, the basin has sufficient natural recharge and groundwater flow toward the west that additional efforts to identify and potentially utilize new recharge areas in the Newhall Ranch Specific Plan area, which is where groundwater is already discharging from the basin, would be counter-productive. To place that in some context, however, artificial recharge methods and their potential applicability in the basin are discussed in some detail below, as is the operating plan for groundwater use in the basin and its associated effects on the prevailing groundwater flow direction and associated groundwater storage and discharge.

Groundwater Recharge Methods

The implied intent of the Specific Plan condition addressed in this technical memorandum is an evaluation of purposeful supplemental groundwater recharge, commonly called artificial recharge, to augment natural recharge processes, presumably to benefit the yield of the basin. By specifically noting that the evaluation of recharge methods should also identify appropriate land areas for recharge, the condition further implies that potential artificial recharge would most likely involve the spreading of surface water for infiltration and deep percolation to the water table. Despite the latter implication, however, rather than limit this overall discussion to potential surface spreading of water for artificial recharge, and recognizing the nature of the aquifer systems in the basin, and particularly in the Specific Plan area, the following discussion of artificial recharge methods is included to provide a context for considering the applicability of artificial recharge in that local setting, and also to provide a context for the recent investigation of the feasibility of injection as a potential recharge mechanism, the results of which are summarized in the next section of this technical memorandum.

In most general terms, artificial recharge can be defined as augmenting the natural movement of surface water into underground formations by some method of construction, by spreading of water, or by artificially changing natural conditions. While a variety of artificial recharge methods have been developed and applied in various areas, they can generally be grouped into three categories: water spreading on the ground surface to increase infiltration, recharging through wells to directly introduce water into the aquifer system, and pumping in proximity to surface water bodies to induce recharge from them.

Of the three general categories of artificial recharge methods, the most widely practiced are water spreading operations, where surface waters are purposely introduced to a spreading basin, or onto selected lands, or into a stream channel such that the water can infiltrate from the surface and then deep percolate to the water table, thus adding to other waters that "naturally" recharge the aquifer, e.g. precipitation, water applied for irrigation, etc. In contrast to surface spreading, artificial recharge of groundwater through wells is much less widely practiced and is typically much smaller in rate of recharge. Individual wells might be capable of recharge rates of a few acre-feet per day, where surface spreading, depending on the nature and physical extent of the spreading ponds or in-channel watercourse, can infiltrate tens to hundreds of acre-feet per day. Despite such limitations, two key factors that lead toward the potential applicability of recharge wells, rather than spreading basins, in some settings are the physical presence of confining layers in the aquifer system that could impede the deep percolation of infiltration from the surface, and the lack of available surface area for surface spreading. In this setting, the nature and depth of the Saugus Formation, which contains alternating layers of fine (confining) and coarse aquifer materials, would likely warrant consideration of recharge wells for those reasons, if artificial recharge of the Saugus were being considered. However, as discussed below, neither recharge method (surface spreading or recharge wells) is warranted in the basin, and particularly in the westerly portion of the Saugus Formation in the vicinity of the Newhall Ranch Specific Plan.

Feasibility of Injection for Saugus Formation Recharge

Early considerations of potential water supply for the Newhall Ranch Specific Plan included so-called Aquifer Storage and Recovery, or "ASR", whereby water from outside the local basin would be imported and injected into the Saugus Formation, where it would be stored for subsequent recovery by pumping for the municipal water requirements of the project. While ASR is not part of the integrated groundwater/imported surface water/reclaimed water supply that is the current and planned future water supply in the valley, the consideration of ASR as a water supply concept for Newhall Ranch resulted in field testing and analysis to assess the hydrogeologic feasibility of injecting and recovering water in the Saugus Formation. That work, briefly summarized as follows, provides some useful insight to potential artificial recharge of the Saugus Formation since it specifically tested both injection (recharge) into, and recovery of water from that aquifer.

A detailed description of the assessment of the hydrogeologic feasibility of injection and recovery in the Saugus Formation, which was conducted in the summer-fall of 2000, is documented in **Assessment of the Hydrogeologic Feasibility of Injection and Recovery of Water in the Saugus Formation, Santa Clarita Valley** (Richard C. Slade & Associates, 2001). That feasibility assessment included the injection of water from Valencia Water Company's municipal distribution system into Valencia's Saugus Well No. 205 for seven day periods at each of 500, 800, and 1,100 gallons per minute (gpm). That injection was followed by a brief (9 days) observation of groundwater storage, followed in turn by pumping (recovery) of water from the same well at its normal operating capacity of about 2,300 gpm over a period of 10 days. During injection, groundwater quality sampling at a nearby production well was conducted to assess any discernable impacts of injection on groundwater quality during injection. During subsequent pumping of the tested injection well, daily water quality sampling was conducted to assess the "recovery" of injected water, followed by extraction of typical formation water quality after recovery of the injected water. Other related work at the time of injection feasibility testing included the separate pumping of another Saugus Formation well, and concurrent observation of groundwater response in a number of wells completed in either the Saugus Formation or the overlying Alluvium. The purpose of the latter testing was to examine the extent of direct effects, if any, of Saugus pumping on the Alluvium.

The results of the testing described above were interpreted by Slade to conclude that it is hydrogeologically feasible to inject (recharge) and recover water in the Saugus Formation. The aquifer readily accepted water from the injection well, and it subsequently yielded a comparable volume to the same well when it was pumped. The measured effects of injection and pumping were indistinguishable from normal seasonal fluctuations in groundwater levels in the Saugus Formation. The yield of the injection/production well, as measured by its specific capacity (injection or pumping rate divided by water level increase during injection, or drawdown during pumping) was determined to be as generally expected; specific capacity during injection was about 60 to 80 percent of specific capacity during pumping, a phenomenon typically attributed to clogging during injection by some combination of sediment and air. Finally, the injection into, and pumping from the Saugus wells were observed to have no measurable effect on water levels in the overlying Alluvial aquifer system.

In the context of this technical memorandum, the conclusions derived from the assessment of hydrogeologic feasibility of injection and extraction in the Saugus Formation can be extrapolated to project that the Saugus can be recharged via injection at capacities that correlate with fractions of the yields of equivalent Saugus production wells. Some amount of clogging of the injection wells can be expected, resulting in a probable need to regularly interrupt injection (recharge) for routine "purging" of the wells by pumping and, probably less frequently, for well rehabilitation of a more complex nature, e.g. using chemical and/or mechanical means to restore and maintain well injectivity. In the more focused context of the Specific Plan condition regarding land areas for potential recharge, the feasibility assessment and conclusions to date suggest that typical well sites, plumbed with provisions to deliver water from the municipal distribution system for injection and also to discharge water from routine and other well rehabilitation efforts, can be adequate to provide for the installation of injection (recharge) wells if artificial recharge of the Saugus were to be desired for some reason. In that light, however, the next section discusses the yield of the local groundwater basin, and the integration of supplemental water supplies with that yield to meet existing and projected water requirements in the basin, including those of the Specific Plan area.

Groundwater Basin Yield

Total water requirements in the Santa Clarita Valley were nearly 88,000 acre-feet in 2004. That total demand represents an average annual increase of about 3.5 percent per year since 1980, when surface water from the State Water Project (SWP) was initially imported to supplement local groundwater for municipal and agricultural water supply. Current groundwater use is lower than peak historic, pre-SWP use, and it has remained within a generally constant range of about 38,000 to 44,000 acre-feet per year over the last 15 years. That historical groundwater use and resultant conditions, i.e. no long-term changes in groundwater levels and storage, have been such that there has been no need to initiate and operate artificial groundwater recharge projects. In effect, natural recharge processes have resulted in recharge that sustains, i.e. refills, the aquifer system sufficiently that there has been no long-term depletion of groundwater. Groundwater levels have remained basically unchanged for several decades throughout the western half of the basin; to varying degrees, groundwater levels in the eastern part of the basin have fluctuated through wet and dry hydrologic cycles, but fully recover through natural recharge processes in wet and normal periods of rainfall and stream flow. Thus, with particular focus on the western portion of the basin where the Specific Plan is located, the aquifer system has remained basically full, discharging to some degree to the Santa Clara River to sustain surface water flows out of the basin and downstream to Ventura County.

Based on empirical observation of groundwater basin conditions in response to historical pumping, and also in recognition of the increases in Santa Clara River flows and related groundwater recharge that indirectly derive in part from increased imported SWP water, the concept of a groundwater operating plan was developed to define the groundwater component of overall water supply in the basin. The groundwater operating plan is also a product of the formal Groundwater Management Plan adopted for the basin in 2003, which incorporates a number of elements aimed at developing groundwater in conjunction with other water supplies to meet existing and projected water requirements, and to do so without overdrafting the groundwater basin. The groundwater operating plan is based on the concept that pumping can vary from year to year to allow increased groundwater use in dry periods and increased recharge during wet periods, and to collectively assure that the groundwater basin is adequately replenished through various wet/dry cycles, thus maintaining the basin in a sustainable condition, i.e. no long-term depletion of groundwater or interrelated surface water. In summary, the operating yield concept has been quantified as ranges of annual pumping volumes as follows:

> **Alluvium** – Pumping from the Alluvial Aquifer in a given year is governed by local hydrologic conditions in the eastern Santa Clara River watershed. Pumping ranges between 30,000 and 40,000 afy during normal and above-normal rainfall years. However, due to hydrogeologic constraints in the eastern part of the Basin, pumping is reduced to between 30,000 and 35,000 afy during locally dry years.
>
> **Saugus Formation** – Pumping from the Saugus Formation in a given year is tied directly to the availability of other water supplies, particularly from the SWP. During average-year conditions within the SWP system, Saugus pumping ranges between 7,500 and 15,000 afy. Planned dry-year pumping from the Saugus Formation ranges between 15,000 and 25,000 afy during a drought year and can increase to between 21,000 and

25,000 afy if SWP deliveries are reduced for two consecutive years and between 21,000 and 35,000 afy if SWP deliveries are reduced for three consecutive years. Such high pumping would be followed by periods of reduced (average-year) pumping, at rates between 7,500 and 15,000 afy, to further enhance the effectiveness of natural recharge processes that would recover water levels and groundwater storage volumes after the higher pumping during dry years.

To examine the sustainability of the groundwater basin under the operating plan, which already derived from observation of actual basin response to generally comparable historical operations, the municipal purveyors in the Santa Clarita Valley commissioned the development and calibration of a numerical groundwater flow model which could be used to project groundwater level and storage response to the variations in pumping planned through wet and dry hydrologic cycles as described in the operating plan. That model was developed and calibrated in 2004 (CH2M Hill, 2004) to simulate the basin's response to the various natural recharge processes (e.g. infiltration of precipitation, infiltration of applied water, infiltration of stream flow) and discharge processes (e.g. pumping, groundwater discharge to streams). The calibrated model was then used to analyze the yield of the basin, i.e. the groundwater operating plan, in 2005 (CH2M Hill and LSCE, 2005). Basin yield was examined by running the model over a 78-year hydrologic period, which was selected from actual historical precipitation to examine a number of hydrologic conditions which could be expected to affect both groundwater pumping and groundwater recharge. The selected 78-year simulation period was assembled from an assumed recurrence of 1980 to 2003 conditions, followed by an assumed recurrence of 1950 to 2003 conditions. The 78-year period was analyzed to define both local hydrologic conditions (normal and dry), which affect the rate of pumping from the Alluvium, and hydrologic conditions that affect SWP operations, which in turn affect the rate of pumping from the Saugus. The resultant simulated pumping cycles included the distribution of pumping among existing and planned Alluvial and Saugus Aquifer wells, for normal and dry years respectively, including the planned restoration of wells that have been impacted by perchlorate in the central part of the basin.

Simulated Alluvial Aquifer and Saugus Formation response to the ranges of pumping under assumed recurrent hydrologic conditions is essentially a long-term repeat of the historical conditions that have resulted from similar pumping over the last several decades in the Alluvium, and consistent with actual experience under smaller pumping rates in the Saugus Formation. The resultant response consists of: (1) generally constant groundwater levels in the middle to western portion of the Alluvium and fluctuating groundwater levels in the eastern portion as a function of wet and dry hydrologic conditions, (2) variations in natural recharge that directly correlate with wet and dry hydrologic conditions, and (3) no long-term decline in groundwater levels or storage. The combination of actual experience with Alluvial Aquifer pumping at capacities similar to those in the operating plan, and the resultant natural recharge of groundwater levels and storage, complemented by modeled projections of similar recharge to future pumping, result in a conclusion that the operating plan represents a sustainable yield of the Alluvium.

In the Saugus Formation, the simulated response consists of (1) short-term declines in groundwater levels and storage near pumped wells during dry-period pumping, (2) rapid recovery of groundwater levels and storage after cessation of dry-period pumping, and (3) no long-term decreases or depletion of groundwater levels or storage. The combination of actual experience with Saugus pumping and recharge up to about 15,000 afy, complemented by modeled projections of aquifer response that show long-term utility of the Saugus at 7,500 to 15,000 afy in normal years and rapid recovery from higher pumping rates during intermittent dry periods, all without any purposeful artificial recharge, shows that the Saugus Formation can be considered a sustainable water supply source to meet the Saugus portion of the operating plan for the groundwater Basin.

As a result of the analysis described in the preceding, i.e. the combination of actual historical basin conditions and simulated future basin conditions, the groundwater operating plan and the natural recharge associated with it have become the existing and projected groundwater supply component of water supply to meet ongoing water requirements in the valley.

For purposes of this technical memorandum, the existence of historical and existing groundwater conditions, combined with the balance of the hydrogeologic setting in the Specific Plan area, indicates that there has been no need for artificial recharge of the aquifer system in that portion of the basin. Since natural recharge processes have maintained long-term stable groundwater conditions, including sufficiently high groundwater storage that there is groundwater discharge from the aquifer to the Santa Clara River, efforts to artificially augment natural recharge in that area could be expected to result in "rejected" recharge, i.e. recharged water would simply add to groundwater discharging from the aquifer system, resulting in no net benefit to the basin's yield or storage. Recent analysis of the groundwater basin's yield and the projected impact of the operating plan for groundwater pumping in the basin shows that future conditions are expected to generally repeat historical observations, resulting in no need for artificial recharge in the western (Specific Plan) portion of the basin.

Need for Saugus Formation Recharge Locations in Newhall Ranch Area

All the preceding description and discussion of the occurrence of groundwater, its recharge and discharge areas, and its sustainable yield maintained by natural recharge processes can be summarized to conclude that there is no definable need to identify land areas for artificial recharge of the Saugus Formation. More specifically, there is no need to identify land areas for artificial recharge of the Saugus Formation in the small part of that aquifer system that underlies the Newhall Ranch Specific Plan area. In summary form, that conclusion derives from the following points.

- The Upper Santa Clara River Groundwater Basin, East Subbasin is comprised of two aquifers, the Alluvium and the Saugus Formation, which are generally recharged in the east to central portion of the basin, well east of the Newhall Ranch Specific Plan area. Groundwater flow in the basin is generally east to west, with resultant groundwater discharge at the western end of the basin.

- The Newhall Ranch Specific Plan area overlies a very small portion of the Saugus Formation at the far western end of the basin, as illustrated in Figure 1, where the basin is discharging water that flows downstream toward Ventura County.

- Historical observations for several decades have shown no long-term changes in groundwater storage or levels. Natural recharge processes have sustained groundwater levels, including long-term essentially constant, high groundwater levels. There has thus been no need for addition of artificial recharge operations to augment natural recharge to the basin.

- The presence of high, relatively constant groundwater levels in the Specific Plan area is indicative of no vacant aquifer storage space into which artificial recharge might be introduced. Thus, attempts to artificially recharge the basin in that area can be expected to result in rejected recharge, or the rapid discharge of any recharged water to the overall outflow from the basin.

- The future operating plan for the basin includes future pumping that is generally similar to historic pumping, with one notable change whereby short-term intermittent increases in Saugus pumping would occur during dry periods when supplemental imported State Water Project deliveries might be reduced. Simulation of basin response to such pumping projects conditions generally comparable to historic experience: future Alluvial aquifer levels and storage comparable to historical conditions; and future Saugus Formation levels and storage lowered during dry periods (in response to increased pumping) but fully replenished by natural recharge processes in subsequent wet/normal conditions.

- While there is no defined need for artificial recharge in the western part of the basin, the nature of the Saugus Formation is such that, physically, recharge to that formation would likely be more effective through injection wells. Thus, if artificial recharge of the Saugus Formation were to become desirable for some reason, feasibility testing of injection has been undertaken, with results showing such a mechanism to be hydrogeologically feasible.

Luhdorf & Scalmanini Technical Memorandum: Potential Capture of Perchlorate Contamination, Valencia Water Company Wells E14-E17
April 26, 2006

Potential Capture of Perchlorate Contamination Valencia Water Company's Wells E14 – E17

PREPARED FOR: Valencia Water Company

PREPARED BY: Joseph C. Scalmanini
William L. Halligan

DATE: April 26, 2006

PROJECT NUMBER: 06-2-008

Introduction

As part of its water supply planning in accordance with the overall groundwater operating plan in the Santa Clarita Valley Groundwater Basin, East Subbasin, Valencia Water Company is in the process of installing four new municipal water supply wells in the western part of its overall service area, generally near the mouth of Castaic Creek Canyon. Those four wells are intended to augment Valencia's groundwater source capacity and, in general, provide municipal pumping capacity in that part of the overall basin that will replace a number of agricultural supply wells in the same area as the latter are abandoned in concert with general land development in the area.

In light of general concerns about perchlorate contamination in the groundwater basin, despite the fact that the focus of that concern is several miles to the east of the new Valencia wells, Valencia commissioned the work reported herein to investigate the risk of perchlorate contamination on its new wells. As a result, the analysis described below was undertaken to examine the potential capture of perchlorate-impacted groundwater by the new Valencia wells, and the results have been interpreted to conclude regarding risk of perchlorate capture at the new wells.

In summary, the approach to investigating potential capture of perchlorate-impacted groundwater by the new wells involved three sequential steps: identification of local and regional groundwater flow patterns in the Alluvium, the aquifer in which all four wells are completed; application of a single layer groundwater flow model to examine the capture zone of the four-well "well field" under planned operating conditions; and interpretation of potential capture of perchlorate via examination of the wells' theoretical independent capture zone relative to known occurrence of perchlorate and its mobility in the Alluvium. The latter step was subsequently augmented by considering other factors, such as the locations and magnitude of pumping between the new wells and the known occurrence of perchlorate, that affect the potential capture of perchlorate by the new wells. Ultimately, conclusion regarding the risk of perchlorate contamination at the new wells was drawn from a combination of the theoretical independent capture zone analysis and the other factors that affect the potential capture of known perchlorate in the basin.

Valencia Wells E14 – E17

Valencia's four new Alluvial wells are numbered E14 through E17. The locations of the new Valencia municipal wells are illustrated in Figure 1, which also shows other nearby wells.

As specified in Valencia's Water Supply Permit issued by the State Department of Health Services (DHS), Valencia's new municipal E wells are replacement wells for some of the nearby Newhall Land and Farming Company's agricultural E wells, e.g. Wells E, E2, E4 and E5, which are in the process of being permanently sealed and abandoned in accordance with the DHS Permit. As land development occurs in the general area of those wells, the need for irrigation water supply will progressively decrease and municipal water demands will correspondingly increase. Thus, in general, the new Valencia wells will generally produce water comparable to the historical production from the NLF wells, resulting in no substantial change in basin operation. Pumping from the basin will thus remain within the operating yield concept incorporated in the 2005 Urban Water Management Plan and analyzed in the 2005 Basin Yield Report.

The four new Valencia E wells are all generally similar in terms of aquifer completion and construction details. All four are completed solely in the Alluvium. All four well sites were explored via pilot hole drilling and logging to about 200 feet, and the four completed wells range in depth from 133 feet (Well E-15) to 170 feet (Well E-16). All four wells are similarly constructed with 18 inch nominal production casing from the ground surface to the top of a single perforated (louvered well screen) intake section. The depths of blank production casing range from 76 feet (Well E-14) to 92 feet (Well E-15). Louvered well screens range in length from 38 feet (Well E-14) to 63 feet (Well E-16). The bottom of the well intake sections ranges between depths of 114 feet (Well E-14) and 145 feet (Well E-16). All four wells have gravel envelopes extending from total depth to just above the top of the intake section, and are sealed above that depth, to the surface, with cement grout. Key well construction details for all four Valencia E wells are summarized in Table 1.

The four new Valencia E wells are intended to be equipped to pump between 1,000 and 1,400 gallons per minute (gpm). Three of the four wells (E-14 through 16) have comparable, high yields as indicated by their respective specific capacities (gpm per foot of drawdown) generally between about 62 and 66 gpm/ft. Well E-17, while still capable of its design capacity of 1,000 gpm, has a notably lower yield, about 34 gpm/ft. Well yield and design capacity details for all four wells are also summarized in Table 1.

At present, Valencia Well E-15 has been equipped with a permanent pump and appurtenant facilities to render it operational at its design capacity of 1,400 gpm. The other three wells have been approved by DHS for addition to Valencia's Water Supply Permit, but have not been equipped pending further development and associated increase in water demands.

Specific Capacity (gpm/ft.)	65.9	62	61.8	34.1

Groundwater Flow

There is no known occurrence of perchlorate contamination in the Alluvium anywhere near the new Valencia E wells. Consequently, it is illogical to think that the E wells, regardless of design capacity or future operation, would induce the movement, or capture, of perchlorate-contaminated groundwater as a result of their pumping. However, to examine what might theoretically be captured by the new Valencia E wells, consideration was given to the limited detection of perchlorate in the Alluvium, about five miles east of those wells, and the general movement of groundwater in the Alluvium, both regionally and locally near the E wells.

In the Alluvium, groundwater flow is generally recognized to be aligned with the Santa Clara River and its tributaries. For the most part, groundwater levels west of Bouquet Canyon remain relatively constant over time, suggesting that both the direction and rate of groundwater flow do not vary widely in that part of the aquifer system. East of Bouquet Canyon, the Alluvium has experienced groundwater level fluctuations of varying magnitudes, generally increasing to the east, through wet and dry periods. Examination of the fluctuations suggests that the overall flow direction has remained westerly and southwesterly beneath the Santa Clara River and its main tributaries respectively, although the rate of groundwater flow has fluctuated as groundwater levels have changed.

More specifically for purposes of this analysis, groundwater flow in the vicinity of the Valencia E wells, and upgradient from the vicinity of the E wells to the area where perchlorate has been detected in the Alluvium, was examined by preparing contour maps of equal groundwater elevation for both wet and dry climatic conditions, i.e. high and low groundwater levels. The resultant contour maps are illustrated in Figures 2 and 3. Unaffected by local groundwater level drawdown directly attributable to pumping operations, groundwater flow directions in the Alluvium, in both wet and dry periods, are generally westerly beneath the Santa Clara River from the vicinity of Bouquet Canyon where the only two Alluvial production wells ever impacted by perchlorate are located. Near the E wells themselves, there is a confluence of groundwater flow, with some southerly inflow beneath Castaic Creek joining the predominant westerly to southwesterly groundwater flow at the mouth of the Castaic Creek Canyon and its confluence with the main Santa Clara River Valley. The hydraulic gradient in both wet and dry periods is approximately 30 feet per mile. The lack of significant differences in groundwater flow directions and hydraulic gradients between the wet and dry periods is consistent with the generally stable groundwater level conditions in the westerly portion of the overall groundwater basin, west of the mouth of Bouquet Canyon.

Considering the locations of the E wells relative to the surrounding groundwater flow directions, a component of flow into the E wells can be expected to be from the upgradient easterly direction. Further considering the confluence of groundwater flow from the north (Castaic Canyon) with the regional flow from the east, it is also likely that a component of flow into the E wells will be from the upgradient northerly direction. Of course, pumping operations at the wells themselves will locally alter the gradient and associated flow directions, potentially resulting in inflow to the wells from cross-gradient and downgradient directions.

Capture Zone Simulation

The nature of drawdown around one or more pumped wells, and the resultant impact on local groundwater flow, i.e. "capture" of groundwater by the well(s), is directly affected by several factors related to the well(s) and the aquifer in which they are completed. Well parameters include pumping capacity and duration of pumping cycles (time). Aquifer parameters include hydraulic conductivity, transmissivity, and storage coefficient of the aquifer materials. Design capacities for all four E wells are listed in Table 1; in summary, they are 1,000 to 1,400 gpm. Pumping cycles for all the Valencia wells are variable as water requirements fluctuate through the year. During peak demand periods, some wells can operate as much as all day, or slightly longer. However, for all Valencia wells as a group, long-term average pumping cycles are about 8 hours per day. For the conservative analytical purposes described herein, drawdown due to pumping of the new Valencia E wells and the associated capture zone formation were based on hypothetical continuous pumping equivalent to intermittent pumping for an average of 8 hours per day. The duration of such hypothetical continuous pumping can be widely varied as a function of other water supply considerations. In light of other perchlorate-related activities in the Valley, with recognition of the plans to start construction later in 2006 for perchlorate control and extraction from the Saugus Formation, the theoretical capture associated with assumed continuous pumping of the E wells was analyzed for a two year period.

In selecting the two year period for theoretical independent capture zone analysis, it should be recognized that there is no absolute nexus between the planned construction of perchlorate containment facilities in the Saugus Formation and any significant change in the Alluvial aquifer that would further protect the E wells. While previous analyses of Saugus containment have included a small component of containment-type capture of Alluvial groundwater, that ultimate effect will be a small incremental addition to the nature of "containment" that results from the regular operation of numerous high capacity Alluvial wells between the E wells and the limited detection of perchlorate in the Alluvium. The capture zone analysis described herein is theoretical and independent in the sense that it purposely ignores the containment and capture effects of all intervening pumping between the E wells and the area of perchlorate detection in the Alluvium. The two year capture zone time period was simply utilized to conservatively examine the potential capture of perchlorate in spite of the actual operation of intervening wells, through a time period until some additional control of migration would be added to the rest of ongoing Alluvial pumping.

A final comment on the two year time period selection is to recognize that, again ignoring the effects of all other Alluvial pumping, in particular the "containment" effects of intervening pumping between the E wells and the historical detection of perchlorate in the Alluvium, the capture zone of the new E wells could theoretically be extended incrementally farther upgradient by simply extending the simulated time period. Ultimately, a scenario could be crafted to show theoretical "capture" of groundwater from an area where perchlorate has been detected. However, such an interpretation would be unrealistic in light of a combination of actual pumping practices and natural processes in the aquifer system as discussed below. In summary, the two-year theoretical independent capture zone is presented for theoretical, conservative illustration purposes; however, it should not be interpreted as the probable real capture zone of the E wells for the collection of reasons discussed below.

Based on interpretation of aquifer tests, and consistent with hydraulic aquifer characteristics used in the recently completed numerical groundwater flow model of the basin, a theoretical, independent capture zone analysis was conducted using a steady-state, single-layer numerical flow model of the Alluvium. The model incorporated specific yield (storage coefficient) and hydraulic conductivity values consistent with the recently completed basin-wide groundwater flow model developed by CH2M Hill. The steady-state model incorporated a specific yield value of 0.1, hydraulic conductivity values that ranged from 105 to 550 feet per day, and transmissivity values that ranged from 200,000 to 600,000 gpd/ft. The model was calibrated to the contours of equal groundwater elevations in the Alluvium presented in the 2004 CH2M Hill regional flow model report. Assumptions incorporated into the model included no change in aquifer storage, which is supported by a review of Alluvium groundwater elevations and the minimal amount of storage change over the past several decades.

As discussed above, the theoretical, independent capture zone analysis simulated the extent of the E Wells capture of groundwater flow over a two-year period. In addition to the conservative nature of the capture zone analysis that ignored all other pumping and related capture or "containment", the E well analysis was further conservative in that it assumed actual operation of all those wells, at their design capacities of 1,000 to 1,400 gpm, when in reality only one of the wells is currently equipped and operational, and the other three wells are not scheduled to become operational until water requirements increase.

Based on a combination of the aquifer characteristics and equivalent full time pumping for two years as described above, assuming all four Valencia E wells are operational, the theoretical independent capture zone for the new Valencia E wells would primarily extend upgradient in two directions: up to about 13,000 feet, or about 2.5 miles, northerly and easterly. The extent and shape of the integrated capture zones of all four E wells is illustrated in Figure 4. The outer bounds of the integrated individual capture zones of the individual wells are illustrated; each individual well's capture zone is a narrower, elongated zone, parallel to the overall integrated capture zone as illustrated in Figure 4.

Perchlorate Contamination in the Alluvium

The overall issue of perchlorate contamination of groundwater in the Santa Clarita Valley has primarily impacted the Saugus Formation, where four municipal wells have been out of service due to perchlorate since 1997. The Alluvium, on the other hand, has been impacted to a notably lesser extent. From the perspective of impacted municipal water supply wells, Santa Clarita Water Division's Stadium well was the first and, for a long time, the only Alluvial well impacted by perchlorate. The Stadium well is located on the south side of the Santa Clara River, upstream of its confluences with Bouquet Canyon and the South Fork of the Santa Clara River. The Stadium well is also located adjacent to the Northern Alluvium area on and immediately adjacent to the northern-most part of the Whittaker-Bermite site. The initial detection of perchlorate in that well was 5.9 g/l in 2002. The Stadium well has been removed from municipal service since the initial detection of perchlorate.

The only other detection of perchlorate in an Alluvial water supply well was in March and April 2005 when Valencia's Well Q2 was found to have low concentrations of perchlorate. Well Q2 is located on the north side of the Santa Clara River, on the west side of its confluence with Bouquet Creek. Initial detection and confirmation sampling of Well Q2 ranged between 9.8 and 11 g/l. After confirmation of perchlorate in April, Valencia temporarily removed the well from service and proceeded with a fast-track permitting and construction program to install wellhead treatment and return the well to service. That work was completed in September and Well Q2 has been in service, with wellhead treatment, since October 2005. Since then, however, the only indications of perchlorate at Well Q2 have been below the analytical detection limit of 4 g/l.

In addition to the limited detection of perchlorate in two municipal supply wells as described above, off-site investigation of perchlorate associated with the Whittaker-Bermite site has identified low concentrations (less than 10 g/l) in shallow Alluvium near Valencia's Pardee well field (Wells N, N7 and N8). Those detections have all been from sampling of shallow groundwater, above 50 feet and also above the intake (screened) sections of those wells. Despite those detections, however, there has been no detection of perchlorate in the nearby, deeper completed production wells.

Whittaker-Bermite has recently initiated actions to pump a production well, and to also extract from several small monitoring wells, as part of perchlorate containment efforts in the Northern Alluvium. The extracted water will be treated for perchlorate removal and then discharged to the Santa Clara River system. These pump and treat activities are intended to subsequently expand as necessary the remediation of perchlorate contamination in the Alluvium, immediately upgradient of the Stadium well, and also upgradient of the other municipal production wells in the vicinity of the Whittaker-Bermite site.

Potential Capture of Perchlorate by Valencia's E Wells

As illustrated in Figure 4, the theoretical independent capture zone of Valencia's new E wells, after an equivalent two year period of continuous pumping of all four wells, would extend toward the area where perchlorate has been detected in two Alluvial water supply wells (Stadium and Q2). However, the capture zone would not extend as far as any historical detection of perchlorate in the Alluvium, whether in production wells or as part of the off-site investigation of the Whittaker-Bermite site. Literal interpretation of the extent of the capture zone and the known detection of perchlorate would be that the E wells can be expected to not capture perchlorate-contaminated groundwater over the time period of analysis, which includes the period of construction and initial operation of facilities to contain and extract perchlorate from the Saugus Formation. However, as discussed above, such an expectation can be interpreted two ways: that the E wells are thus not a risk or, conversely, that the E wells could be at risk if the capture zone analysis were simply extended for sufficient time to encounter areas of perchlorate detection. As also discussed above, the planned containment and extraction of perchlorate in the Saugus Formation is expected to have a small effect on the Alluvium, but not to the extent that it will sufficiently contain perchlorate that downgradient wells can be considered to be protected. Thus, it could be reasoned that the capture zone should be analyzed for a longer pumping period, i.e. beyond the two years related to construction of the Saugus containment facilities. In simple summary, given the nature of groundwater flow direction and the hydraulic properties of the Alluvial aquifer, it is possible to model sets of conditions that would result in theoretical "capture" of groundwater from the area where perchlorate has been detected in the Alluvium. However, recognizing that such a result could be simulated, it should also be recognized that, for the reasons discussed below, such a result should not be interpreted to conclude that the E wells are at risk. In fact, it is logical to conclude, again for the reasons discussed below, that the E wells are likely not at risk.

Upgradient of the E wells in the direction of perchlorate detection in the Alluvium are several high capacity production wells, all of which are artificially removed from the simulated capture zone analysis, but all of which represent actual pumping locations that provide a combination of containment in the aquifer and potential capture of perchlorate if it were to mobilize that far from where it has been detected. For reference with regard to mobility, as discussed above, sampling of shallow portions of the Alluvium near the Pardee well field has detected low concentrations of perchlorate, but the nearby production wells have not detected any perchlorate. Ongoing pumping for water supply since the initial detections of perchlorate (in the Saugus Formation in 1997 and in the Alluvium in 2002) have resulted in only one additional Alluvial production well impact: Valencia's Well Q2 which was briefly impacted but has not detected perchlorate since it was equipped with wellhead treatment and returned to service in October 2005. All other

Alluvial wells between the Whittaker-Bermite site and the E wells have not been impacted despite closer proximity to detected perchlorate and regular water supply pumping for at least four years since perchlorate was first encountered.

The Alluvial production wells between the E wells and the area of detected perchlorate can be considered in three groups, progressively farther from the E wells: the S well field (Wells S6, S7, and S8); the Pardee well field (Wells N, N7 and N8); and Well Q2. Collectively, all those wells have a total pumping capacity of nearly 13,500 gpm, or nearly three times the total design capacity of the E well field. The S well field has existing pumping capacity of 6,000 gpm; the Pardee well field has existing pumping capacity of 6,250 gpm; and Well Q2 is equipped to pump and treat 1,200 gpm. Collectively and as individual wells or groups of wells, those various wells represent significant local pumping locations that provide a form of "containment", if perchlorate were to migrate to any of those areas, against further downgradient movement; and they represent significant extraction rates that would also extract perchlorate, again if it were to migrate to any of those areas. As described above, Well Q2 is already equipped to treat any perchlorate if it were to re-impact that well. The other intervening wells are not equipped with wellhead treatment; however, as is also the case at the E wells, all are designed with wellhead space and provisions for installation of treatment facilities, as was rapidly done at Well Q2 when perchlorate was detected, to enable their continued operation for perchlorate containment and extraction if they are impacted. Thus, the collective intervening wells represent a real pumping scenario that, in effect, produces pumping interruptions of the independent, theoretical capture zone of the E wells described and illustrated above.

In light of all the preceding, it can be concluded that, while a theoretical capture zone can be simulated to show that, with sufficient extended pumping, the new Valencia E wells might "capture" groundwater from areas where perchlorate has been detected in the Alluvium, such a capture zone analysis would necessarily be overly theoretical and conservative because it ignored the intervening effects of numerous other high capacity pumping. It also ignored the actual observations that have shown no detection of perchlorate in all but one of those intervening wells after at least four years of regular pumping operations since initial detection of perchlorate in the Alluvium. The presence of those wells, combined with the existing wellhead treatment at one of them and the provisions for installation of treatment at all the others if ever necessary, represents significant containment of potential perchlorate migration toward the E wells, again assuming perchlorate first migrates as far as the intervening wells. Thus, it can be concluded that the E wells are not at risk of capturing perchlorate from areas in the overall Alluvial aquifer system where it has previously been detected.

EXECUTIVE SUMMARY

This report presents a reclaimed water system master plan for the Castaic Lake Water Agency (CLWA). CLWA wholesales State Water Project (SWP) water to four domestic water purveyors in the Santa Clarita Valley. The purveyors use the SWP water to supplement local groundwater supplies. Currently, the water available to users within CLWA's boundaries meets the demand; however, it is anticipated that demands will exceed supplies within the next twenty years. Accordingly, CLWA is evaluating reclaimed water as an additional reliable water source available to meet its future water demands.

WATER SUPPLY AND DEMAND

Water demands in the Santa Clarita Valley are currently met by two sources: the SWP and local groundwater supplies. The estimated average total supply for municipal and industrial (M&I) and agricultural uses is 98,000 to 109,000 acre-feet per year, depending on the yield available from the local groundwater aquifers. The four purveyors that purchase imported water from CLWA generally serve only M&I demands. In 1992, the total M&I water demand for the CLWA service area was approximately 42,600 acre-feet.

CLWA's future water supply will continue to come primarily from the same two sources: the SWP and local groundwater supplies. The projected water supply available for M&I uses in the year 2010 is 91,500 acre-feet per year (a portion of the total available supply will be used for agricultural purposes). The total M&I water demand in the year 2010 is projected to be approximately 108,000 acre-feet per year, resulting in a potential shortfall of up to 16,500 acre-feet of water in the year 2010.

RECLAIMED WATER FACILITIES AND CHARACTERISTICS

The County Sanitation Districts of Los Angeles County (CSDLAC) own and operate two water reclamation plants (WRPs) within the Castaic Lake Water Agency service area: the Saugus WRP and the Valencia WRP. Current combined treatment capacity of the two plants is 13.1 million gallons per day (mgd). The Saugus WRP operates near its design capacity, which is 5.6 mgd. The Valencia WRP has a design capacity of 7.5 mgd and is currently undergoing expansion to 11 mgd. The ultimate capacity of the plant is planned to be 22 mgd, bringing the ultimate combined capacity of the plants to 27.6 mgd. The Saugus WRP is not planned for expansion in the future; excess flows will be treated at the Valencia WRP. The expected average production of the plants in the year 2010 is 24.5 mgd. The water at both plants is treated to tertiary standards and discharged to the Santa Clara River, an unlined stream.

Review of effluent quality data indicates that the effluent of the plants is suitable for irrigation use. The high concentrations of nitrogen and phosphorus in the effluent are actually beneficial to most vegetation. Conversely, the moderately high levels of salinity and boron in the water can be toxic to plants; therefore, vegetation with a tolerance for salt and boron are recommended. In addition, adequate soil drainage should be provided.

POTENTIAL RECLAIMED WATER USERS

Examination of water consumption records, land use maps, and general plans for the City of Santa Clarita and the County of Los Angeles and discussions with City and County personnel, water purveyors and land developers resulted in identification of existing and future potential users of reclaimed water in the Santa Clarita Valley. The initial list was reduced by defining a service area based on the location of concentrated demand and the location of users with a relatively high demand. The list was further reduced based on the relative cost of providing service.

The proposed reclaimed water system will deliver approximately 9,100 acre-feet of water per year for the following uses:

- 3,700 acre-feet for eight golf courses.
- 1,300 acre-feet for parks.
- 1,000 acre-feet for schools.
- 1,100 acre-feet for residential landscaping.
- 500 acre-feet for commercial/industrial landscaping.
- 700 acre-feet for use at a cogeneration plant.
- 500 acre-feet for use at Six Flags Magic Mountain amusement park.
- 300 acre-feet for other uses which include cemetery landscaping, freeway landscaping, and Christmas tree farms.

Peak day demand is estimated to be 18 mgd. Most of the uses are for landscape irrigation, although Six Flags Magic Mountain will use the water for filling their lakes and ponds that feed the water rides and for washing down patios and walkways. Other uses include irrigation of Christmas tree farms and use at a cogeneration plant.

An additional 1,200 acre-feet of demand for the Stevenson Ranch development has been identified in an area outside CLWA's service area boundary; however, the developer has indicated that it is pursuing annexation. This demand is considered optional and is identified separately.

The proposed reclaimed water system is divided into 5 service zones based on elevation. Zone V serves the portion of Stevenson Ranch outside CLWA's boundary.

RECOMMENDED RECLAIMED WATER SYSTEM

The components of the proposed reclaimed water system, excluding Zone V, are listed below. The quantities in parentheses following each item indicate the total of each item if Zone V were included.

- Two reuse pump stations to be located at the Saugus and Valencia Water Reclamation Plants, the combined capacity of which will be 13,000 gallons per minute (gpm). (15,000 gpm)

- Eight above-ground, steel reservoirs ranging in capacity from 700,000 to 3.1 million gallons (MG) and providing a total storage capacity of 13.6 MG. (9 reservoirs, 15.5 MG)

- Approximately 275,000 feet of high pressure PVC pipe ranging from 6 to 24 inches in diameter. (300,000 feet)

- Four pipeline crossings of the Santa Clara River supported by existing bridges.

- Two pipeline crossings of Interstate 5 supported by existing bridges.

- Six booster pump stations ranging in capacity from 1,200 to 5,000 gpm. (7 booster pump stations)

The estimated construction cost of the proposed reclaimed water system excluding Zone V is approximately $30 million (1993 dollars). The estimated construction cost including Zone V is $33 million (1993 dollars).

CONSTRUCTION PHASING

It is recommended that the reclaimed water system be implemented in eight phases. The reclaimed water system was divided into implementation phases based primarily on service zone boundaries, and location and status (existing or future) of potential users. Zone I was divided into three subzones: IA, IB, and IC. Zone III was divided into two subzones: IIIA and IIIB. Zone V serving Stevenson Ranch is not included in the 8 phases and would most likely be a separate phase implemented following Phase 8. The implementation phases were prioritized based on the status of the users, the anticipated construction schedule of future users, and the proximity of the users to the Valencia and Saugus WRPs. Plate 4 delineates the implementation phases. Facility locations were not identified for Phase 8 (Zone IV), because it is scheduled for construction after the year 2010. Table ES-1 summarizes the reclaimed water users to be served by each phase and the corresponding demands, Table ES-2 summarizes the facility reqoirements for each phase, and Table ES-3 summarizes the construction cost of each phase. Costs for the phases range from $1.9 million to $6.0 million (1993 dollars).

PERMIT/INSTITUTIONAL REQUIREMENTS

A number of permits and approvals will be required for each phase of the recommended plan. Because the permitting process can be lengthy, the permitting requirements may affect the implementation schedule of the reclaimed water system. A summary of the regulatory requirements is shown in Table ES-4.

In addition to the permits and approvals summarized in Table ES-4, compliance with the California Environmental Quality Act will be required. Environmental documentation for 1,700 acre-feet of reclaimed water use was completed in 1991 and consisted of two primary documents:

- CLWA's "Final Program EIR for the Capital Program and Water Plan including Acquisition of Supplemental Water and Proposed Second Plant Site".
- CLWA's "Site Specific Mitigated Negative Declaration for Construction of a Reclaimed Water Distribution System".

These documents are applicable to Phase I of the proposed project. It appears that a supplemental EIR would be appropriate for the remainder of the master plan followed by a negative declaration for each phase of the plan.

It will also be necessary to secure agreements between the following entities:

- CSDLAC and CLWA
- CLWA and the water purveyors
- The water purveyors and users

IMPLEMENTATION SCHEDULE

Because the availability of reclaimed water is dependent upon the production of the Valencia and Saugus WRPs, the recommended implementation schedule for the reclaimed water system is based on the projected flows from the WRPs. The recommended implementation schedule is presented on Plate 5.

FINANCING

To implement construction of the reclaimed water system, sufficient capital and operating funds must be secured by CLWA. Financing options available to CLWA include the following:

- Capital Improvement Program (CIP) Funds
- Water Reclamation Loan Program (WRLP)
- State Revolving Fund (SRF)
- Small Reclamation Projects Act of 1956

CLWA has included additional water supply projects such as the recommended reclaimed water projects in the CIP used to compute its connection fees. However, due to the low interest rates of the WRLP and SRF, it is recommended that CLWA consider maintaining its accumulated reserves for other purposes and finance the reclaimed water project through the WRLP or SRF. According to SWRCB staff, WRLP funds are very limited in the near future; SRF funds are generally more readily available. It should be noted that use of the WRLP or SRF will include detailed review of project planning and construction documents by the State Water Resources Control Board.

Pursuit of Small Reclamation Projects Act funds (Bureau of Reclamation) is an alternative; however, the interest rate is higher than that of the WRLP or SRF. In addition, the Act focuses on projects providing facilities for commercial irrigation. Phases of the reclaimed water project that include irrigation of tree farms would meet the requirements; however, funding of these phases would most likely be low priority because commercial irrigation is such a small percentage of these phases. Consequently, the WRLP and SRF are recommended over the Small Reclamation Projects Act.

WATER RATE POLICY

To encourage its use, reclaimed water should be available at a lower rate to users than potable water. The wholesale rate of potable water is currently $145 per acre-foot. The unit cost of the reclaimed water system, including annualized capital, is $391 per acre-foot ($385 per acre-foot including Zone V).

This cost assumes CLWA finances construction of the project through the WRLP or SRF. Because CLWA can utilize CIP funds to repay WRLP or SRF debt service, it will not be necessary to recover capital costs. The average unit cost of reclaimed water excluding annualized capital is $146 per acre-foot with or without Zone V or approximately equivalent to the wholesale rate of potable water.

It is recommended that CLWA utilize a wholesale reclaimed water rate equivalent to the potable water rate and that the water purveyors utilize a retail reclaimed water rate equivalent to the potable water rate. In order to provide an incentive to reclaimed water users, it is recommended the CLWA issue a monthly rebate directly to the reclaimed water users. The recommended initial rebate is $60 per acre-foot. Based on existing retail potable water rates, the rebate would result in a cost incentive for reclaimed water users of 20 to 25 percent over potable water costs.

ENVIRONMENTAL CONSIDERATIONS

The effluent from the two WRPs discharges into the Santa Clara River, an unlined river. In fact, in summer months, it appears that the effluent comprises the majority of the river's flow. Some water may be contributed by rising groundwater, agricultural runoff and other small contributors. Because effluent from the WRPs flows through riparian habitat of two endangered species, determination of the impact of a reclamation project on the habitat and development of mitigation measures is important. The endangered species thought to live in the river habitat include the unarmored three spine stickleback (a fish) and the least bell's vireo (a bird).

Although average annual discharges to the river are projected to increase even after implementation of the recommended reclaimed water system, discharges are anticipated to decrease from May through September and increase from October through April due to the expected reclaimed water use patterns.

SEASONAL STORAGE

It is recommended that seasonal storage be considered as a means of mitigating potential impacts to the river flows. Two potential dam and reservoir sites have been identified: Oak Spring Canyon and Charlie Canyon. If reclaimed water is collected in a reservoir for six months of the year and released to the river during the two peak irrigation months, a higher river flow can be maintained in the summer months. The preliminary construction cost estimate of providing seasonal storage, including modifications to the recommended reclaimed water systems, is approximately $5.1 million for the Charlie Canyon site and $14.4 million for the Oak Spring Canyon site. A number of investigations and studies must be conducted in order to determine the feasibility of the reservoirs and to estimate the costs more accurately.

CHAPTER 1

INTRODUCTION

This chapter presents a brief background of the Castaic Lake Water Agency (CLWA) and the need for a reclaimed water system. The objectives and conduct of the project are summarized.

BACKGROUND

CLWA has a contract with the State of California to purchase water from the State Water Project (SWP) and wholesale it to four domestic water purveyors in the Santa Clarita Valley. The imported water is delivered to Castaic Lake through State facilities. From Castaic Lake, which is the terminal reservoir of the SWP's West Branch, it is treated in CLWA's Earl Schmidt Filtration Plant and delivered to the water purveyors through transmission lines owned and operated by CLWA.

The four water purveyors primarily serve municipal and industrial customers. In normal years, approximately 50 percent of the municipal and industrial (M&I) demand in CLWA's service area is met with imported water. However, because of the recent drought, the imported water supply has decreased significantly. In 1992, only 25 percent of the M&I demand was met with imported water. The balance was met with local groundwater provided by the purveyors. Agricultural water users also exist within CLWA's boundaries. The main sources of water for these water users are privately owned wells.

Currently, the water available to users within CLWA's boundaries meets the demand; however, it is anticipated that demands will exceed supplies within the next twenty years. Additional reliable sources of water are necessary to meet the future water demands. CLWA has recognized that reclaimed water is one such source.

The County Sanitation District of Los Angeles County (CSDLAC) owns and operates two water reclamation plants within the CLWA service area. The water is treated to tertiary standards and discharged to the Santa Clara River. By utilizing the effluent from the water reclamation plants for irrigation and other non-potable purposes, CLWA can more efficiently allocate its potable water and increase the reliability of water supplies in its service area.

OBJECTIVES

The objectives of this project are as follows:

1. Identify potential users of reclaimed water.

2. Assess the reclaimed water demand and supply characteristics.

3. Select an appropriate service area for a distribution system.

4. Prepare a master plan to serve as a guide for implementing a cost effective system to meet the needs of the potential users.

CONDUCT OF THE STUDY

The information developed in this master plan is a result of existing sources of information; contact with CSDLAC, local water purveyors, the City of Santa Clarita and potential water users; office analysis and computer modeling. Initial phases of the project were concerned with the evaluation of existing data and reports. Discussions with the operations and engineering staffs of CSDLAC were conducted to assess water supply characteristics and operational constraints.

Information from discussions with the local purveyors and the Planning Department of the City of Santa Clarita led to identification of potential existing and future reclaimed water users. Water demand characteristics, including time-of-use, were assessed through discussions with these potential users. Through analysis of data and computer modeling, a master plan for a cost effective reclaimed water system was developed. Construction costs were estimated and a construction schedule was prepared.

CHAPTER 2

STUDY AREA CHARACTERISTICS

To identify an appropriate service area for a reclaimed water distribution system, information regarding land use and population is important. This chapter describes the current and projected land use and population within the Castaic Lake Water Agency (CLWA).

LAND USE

The CLWA service area encompasses approximately 195 square miles within the upper Santa Clara River Basin, much of which is known as the "Santa Clarita Valley." (See Figure 2-1 for location.) While the majority of CLWA is in the County of Los Angeles, approximately 20 square miles in the westerly part of CLWA extend into an unincorporated area of the County of Ventura. As shown on Figure 2-2, CLWA encompasses the City of Santa Clarita and the communities of Castaic, Val Verde, and Castaic Junction.

Although a portion of the CLWA service area lies within Ventura County, the primary areas of development within CLWA are basically the same as those within the Santa Clarita Valley planning area of the County of Los Angeles. The Santa Clarita Valley Areawide General Plan (adopted 16 February 1984 and amended in December 1990), prepared by the County of Los Angeles, and the City of Santa Clarita General Plan (adopted 26 June 1991) contain the land use plan and development policies for the Santa Clarita Valley planning area within Los Angeles County.

The Santa Clarita Valley includes a variety of residential, commercial, industrial, institutional, agricultural, and open space uses. A large portion of the valley is not suitable for development due to steep terrain, flooding potential or federal jurisdiction (Angeles National Forest). However, rapid residential, commercial, and industrial development of portions of the valley floor and canyons has occurred due to growth influences of the Los Angeles metropolitan area and the presence of three major highways (U.S. Interstate 5/the Golden State Freeway, State Highway 14/the Antelope Valley Freeway, and State Highway 126).

According to the City of Santa Clarita General Plan, 33,647 acres have been developed in the Santa Clarita Valley planning area, including 19,579 acres for residential purposes, 1,881 acres for commercial purposes, and 2,034 acres for industrial purposes. (See Figure 2-3.) In addition, there are 73,192 undeveloped acres in the valley.

The County of Ventura has designated the 20 square-mile area of the county that lies within the CLWA service area to be "Agricultural" (40 or more acres minimum lot size) and "Open Space" (10 acres or more minimum lot size).

1987 population projections for the Santa Clarita Valley compared to the previous (1980 General Plan) population projections for the Valley. The 1987 amendment predicts that the Santa Clarita Valley will grow to a population of 270,000 in the year 2010, a 75 percent increase from the estimated population of 153,900 in the year 1990 (City of Santa Clarita General Plan, adopted 26 June 1991). Compared to other regions in the County, the Santa Clarita Valley is predicted to experience the greatest rate of population, housing, and employment growth.

Population estimates for the 20 square mile area of CLWA within Ventura County indicate a current population of approximately 115 people. The County of Ventura projects a population of approximately 160 by the year 2010.

CHAPTER 3

EXISTING AND PROJECTED WATER SUPPLY AND DEMAND

In order to evaluate the need for reclaimed water, water supplies and demands were projected into the future. This chapter describes the existing and future water supplies, demands, and facilities within the Castaic Lake Water Agency (CLWA) service area.

EXISTING WATER SUPPLY, DEMAND AND FACILITIES

Water Supply

Water demands in the Santa Clarita Valley are currently met by two sources: the State Water Project (SWP) and local groundwater supplies. The estimated average total supply available for municipal and industrial (M&I) and agricultural uses is 98,000 to 109,000 acre-feet per year, depending on the yield available from the local groundwater aquifers. CLWA purchases State water and wholesales it to four domestic water purveyors, these being the Los Angeles County Waterworks District No. 36, the Newhall County Water District, the Santa Clarita Water Company and the Valencia Water Company. The approximate boundaries of the water purveyors are shown on Figure 3-1. CLWA has SWP entitlements of 41,500 acre-feet per year for M&I uses. In addition, SWP agricultural entitlements of 12,700 acre-feet per year have been transferred to CLWA from the Devil's Den Water District in Kern and Kings Counties. To date, the Devil's Den entitlements have not been used within the CLWA service area.

In addition to imported water, local groundwater supplies have been developed by domestic water purveyors and by agricultural water users. Two fresh-water bearing aquifers, the alluvial and Saugus aquifers, underlie CLWA's boundaries and form the Eastern Groundwater Basin of the Santa Clara River Valley Basin.

The alluvial aquifer lies above the Saugus aquifer and is comprised of the alluvial sediments along the river and its major tributaries. The maximum thickness of the alluvium is about 200 feet. A large number of wells penetrate this upper aquifer, and, historically, most water extracted from the groundwater basin has been from the alluvial aquifer. The perennial yield of the aquifer is considered to be 32,500 acre-feet, a portion of which is used for agricultural purposes and is increasingly available for M&I uses as agricultural land is developed for urban use.

Much less information is known about the Saugus aquifer. Historically, few wells penetrated the Saugus aquifer. However, as water demands in the valley have increased, more wells have been drilled into the aquifer. The anticipated annual

POPULATION

The primary areas of concentrated population within CLWA are in the Santa Clarita Valley in the County of Los Angeles. Growth in the Santa Clarita Valley proceeded at a slow pace through 1950. However, since 1950, the population has continually increased at a rapid pace. Table 2-1 depicts the population growth in the valley between 1930 and 1990.

TABLE 2-1

SANTA CLARITA VALLEY HISTORICAL POPULATION GROWTH
1930-1990 (1)

YEAR	POPULATION	CHANGE	AVERAGE ANNUAL PERCENTAGE CHANGE
1930	2,562	-	-
1940	4,047	1,485	5.8%
1950	8,045	3,998	9.9%
1960	14,987	6,942	8.6%
1970	49,997	35,010	23.4%
1980	79,015	29,018	5.8%
1990 (2)	153,900	74,885	9.5%

(1) Source: County of Los Angeles, Department of Regional Planning, June 1984.

(2) Estimate from City of Santa Clarita General Plan, adopted 26 June 1991.

The 1980 County of Los Angeles General Plan estimated population projections for a 25 year time frame (1975-2000). To a significant degree, these projections reflected a perception that slow growth trends evident in the early 1970's would persist within Los Angeles County. However, growth trends of the last decade have confirmed an increasingly rapid growth rate in the region due to rising immigration rates and increasing annual birth rates. This trend is projected to continue in the foreseeable future.

In 1987, the County of Los Angeles Board of Supervisors adopted an amendment to the County General Plan which revised and extended population, employment, and housing projections (Sub-Plan Amendment 87-275). Table 2-2 presents the

aquifer recharge ranges from a minimum of 11,000 acre-feet in dry years to a minimum of 22,000 acre-feet in wet years.

Presently, about one-third of the supply in the Saugus aquifer has been tapped. Agricultural use of the Saugus aquifer is considered to be less than 100 acre-feet per year.

Water Demand

The four purveyors that purchase imported water from CLWA generally do not serve agricultural water users. Therefore, only M&I demands are included in the total demands for CLWA. In 1992, the total M&I water demand for the CLWA service area was 42,600 acre-feet or 39 to 43 percent of the available supply. Of that, approximately 30,900 acre-feet was pumped from local groundwater supplies, and 11,700 acre-feet was from the SWP. As previously discussed in Chapter 1, imported water supply in normal pre-drought years provided approximately 50 percent of the M&I demands. Because of recent drought conditions, however, the imported water supply decreased to approximately 25 percent in 1992. Peak water demands occur from May through October.

Facilities

Currently, CLWA treats the imported water stored in Castaic Lake at the Earl Schmidt Filtration Plant and delivers it to the water purveyors through a transmission system. The main transmission line, the Castaic Conduit, is located east of the Golden State Freeway and parallels the general direction of the Golden State Freeway and Magic Mountain Parkway from Castaic Lake to a point just north and west of Bouquet Junction where two laterals begin. The Honby Lateral roughly follows the north side of the Santa Clara River to the east, where it crosses to the south to serve Saugus. Headed in a southerly direction, the Newhall Lateral parallels San Fernando Road to serve Newhall and Valencia. The conduit system is shown on Figure 3-2.

Although no wells are owned or operated by CLWA, the purveyors have active wells in both the alluvial and Saugus aquifers.

FUTURE WATER SUPPLY, DEMAND AND FACILITIES

Water Supply

CLWA's future water supply will continue to come from two main sources: the SWP and groundwater. (See Table 3-1.) The SWP entitlement includes CLWA's M&I entitlements of 41,500 acre-feet per year and the Devil's Den Water District agricultural entitlements of 12,700 acre-feet per year which have been transferred to CLWA. Because CLWA is currently not utilizing its full M&I entitlement, it has

TABLE 3-1

CLWA PROJECTED WATER SUPPLY AND DEMAND

YEAR	TOTAL NET M&I DEMAND(1) (acft/yr)	AVAILABLE SUPPLY (acft/yr)				TOTAL AVAILABLE SUPPLY (acft/yr)	SUPPLY(5) LESS DEMAND (acft/yr)
		Alluvial(2) 32,500 (acft/yr)	Saugus (3) 20,000 (acft/yr)	SWP M&I(4) 41,500 (acft/yr)	Devil's(4) 12,700 (acft/yr)		
1993	60,769	23,913	20,000	8,257	2,527	54,697	(6,072)

(1) Assumes conservation, other than drought related conservation, begins in 1992 at 1% of the total projected demand and increases to a maximum of 10% in 2001.
(2) The amount available for M&I use is 32,500 acft/yr less the agricultural demands, which are assumed to decrease by 3% per year.
(3) Assumes 20,000 acft/yr is available to M&I users and 2,000 acft/yr is available to other users.
(4) Based on a model prepared by Glenn M. Reiter & Associates.
(5) Parenthesis indicate negative number.

not been necessary for CLWA to utilize Devil's Den water within CLWA. Consequently, the water is currently utilized for agricultural lease operations within the Devil's Den Water District.

The SWP release pattern from its storage reservoir is based on maintaining a supply of water to satisfy demand in a drought. Consequently, SWP entitlements are subject to cutbacks. To assess potential future reductions, Glenn Reiter & Associates created a model of the SWP supply available for release using Monte-Carlo iteration, a random analysis, to estimate project yield. Historical hydrologic data are incorporated into the analysis. Because the State plans to develop additional sources of water in the future, the Reiter model includes scenarios for each projected yield increase. Potential reductions to CLWA's deliveries (assuming full entitlement amounts are requested), and thus the projected SWP water available for CLWA's use, are calculated for each scenario. (See Table 3-1.)

The sources of groundwater available to users within CLWA's boundaries in the future will continue to be the alluvial and Saugus aquifers. From the alluvial aquifer the safe yield is anticipated to be 32,500 acre-feet per year, a portion of which will be used for agricultural purposes and, therefore, is not available for M&I use. The Saugus aquifer production is anticipated to be 21,000 to 22,000 acre-feet per year of which 20,000 acre-feet per year is assumed to be allocated for use by M&I users within CLWA's boundaries and 2,000 acre-feet per year is utilized by other water users.

Water Demand

Projection of CLWA's total M&I water demand through the year 2010 is predicated on expected growth in the area. The total M&I water demand in the year 2010 is predicted to be more than three times greater than the current demand. It is assumed that water conservation, other than drought-related conservation, will increase gradually until it reaches 10 percent of the total water demand. The net water demand results when conservation is subtracted from the total water demand. By the year 2010, the net demand, based on these assumptions, will be 2.7 times more than the current demand.

Although agricultural water demands are not included in CLWA's total demands, it is necessary to project them so that the quantity of groundwater available to meet CLWA's demands can be calculated. For this evaluation, a reduction in agricultural demands of 3 percent per year is assumed.

As shown in Table 3-1, the total available supply in the years 2006 through 2010 does not meet the total net M&I demand during years of reduced SWP deliveries.

Proposed Facilities

CLWA's current capital improvement program includes extensive additions to its water treatment and transmission facilities, as well as several other major facilities including a hydroelectric plant. Among the proposed facilities are the following:

1. Improvements to the Earl Schmidt Filtration Plant to meet anticipated drinking water standards.

2. Expansion of the intake pump station, untreated water pipe-lines, and Earl Schmidt Filtration Plant from 25 million gallons per day (mgd) to 50 mgd.

3. Connection to Metropolitan Water District's (MWD) Foothill Feeder, new untreated water pipeline, intake pump station, and 90 mgd water treatment plant, (to be built in three 30 mgd increments the first of which is currently under construction).

4. Parallel transmission pipelines to the Newhall and Honby Laterals.

5. Extension of the Honby Lateral eastward to Canyon Country.

6. Extension of the Newhall Lateral southward.

7. New Ventura Lateral from the Castaic Conduit westward to the Los Angeles/Ventura County boundary.

8. Emergency storage facilities (88 million gallons).

CHAPTER 4

RECLAIMED WATER CHARACTERISTICS AND FACILITIES

Because the extent of the reclaimed water system is dependent on the amount of reclaimed water available, as well as the quality of the water, this chapter presents an overview of reclamation facilities, flow, and quality in the Santa Clarita Valley.

RECLAMATION FACILITIES

Existing Facilities

The County Sanitation Districts of Los Angeles County (CSDLAC) provide wastewater collection, treatment, and disposal services to residents of two sanitation districts in Santa Clarita Valley: District Nos. 26 and 32. District No. 26 serves the eastern portion of the valley, and District No. 32 serves the western portion of the valley. The majority of the two districts' service areas lie within the City of Santa Clarita.

CSDLAC operates two wastewater treatment facilities in the Santa Clarita Valley. Located within District No. 26, the Saugus Water Reclamation Plant (WRP) is southeast of the intersection of Bouquet Canyon Road and Soledad Canyon Road. (See Figure 4-1.) The Valencia WRP is located within District No. 32 and is on The Old Road near Magic Mountain Amusement Park. (See Figure 4-2.) Schematics of the plants' processes are presented on Figures 4-3 and 4-4.

The two treatment facilities operated independently until 1980, at which time the two plants were linked by a bypass interceptor. The interceptor was installed to transfer a portion of flows received at the Saugus WRP to the Valencia WRP. In order to improve operating efficiencies and because shortage of space at the Saugus WRP limits future expansion of wastewater facilities in District No. 26, a joint powers agreement was enacted in 1984, creating the Santa Clarita Valley Joint Sewerage System. Through use of wastewater and sludge connecting lines, future expansions of treatment works, including sludge handling and disposal operations, will be provided at the larger Valencia WRP.

Current combined treatment capacity of the Valencia WRP and Saugus WRP is 13.1 million gallons per day (mgd). The Saugus WRP has a dry weather, average daily flow, design capacity of 5.6 mgd. Peak sanitary flow design capacity is 10.1 mgd, and peak storm flow design capacity is 12.4 mgd. The dry weather, average daily flow, design capacity of the Valencia WRP is 7.5 mgd. Peak sanitary flow design capacity is 15.0 mgd, and peak storm flow design capacity is 16.5 mgd.

The primary sources of wastewater to the Saugus and Valencia plants are domestic. Both plants are tertiary treatment facilities and produce high quality effluent. Currently, the effluent from the two plants discharges to the Santa Clara River. The Saugus WRP effluent outfall is located approximately 400 feet downstream (west) of Bouquet Canyon Road. Effluent from the Valencia WRP is discharged to the Santa Clara River at point approximately 2,000 feet downstream (west) of "The Old Road" Bridge.

Improvements and Expansions

To accommodate anticipated growth in the Santa Clarita Valley and to ensure compliance with discharge requirements of the California Regional Water Quality Control Board, Los Angeles Region (RWQCB-LA), CSDLAC is planning to expand the Valencia WRP. The ultimate capacity of the plant is planned to be 22 mgd bringing the ultimate total for both plants to 27.6 mgd. Construction will occur in phased increments.

The first phase of construction for the Valencia WRP started 8 September 1992 and is expected to be completed by April of 1994. The dry weather, average daily flow, design capacity will be 11 mgd. Peak sanitary flow design capacity will be 22 mgd, and peak storm flow design capacity will be 25 mgd.

RECLAIMED WATER FLOW

Historic Flows

Recent modifications have been made to the Saugus WRP. In 1991, abandoned sludge digester tanks were converted to primary equalization tanks, which improved plant operations and increased plant capacity from 5.0 mgd to 5.6 mgd. Before the 1991 modifications, the Saugus WRP had been operating close to the average daily flow design capacity of 5.0 mgd. Average daily flow rates during the period from 1984 through 1991 are summarized in Table 4-1. From 1984 through 1986 and in 1990, flow rates were slightly above the design capacity of 5.0 mgd. From 1987 through 1989, flow rates were slightly below 5.0 mgd. Flows previous to 1991 that were above 5.0 mgd were diverted to the Valencia WRP through an interceptor line. Monthly average daily flow rates in 1991 ranged from 4.64 mgd in April to 5.85 mgd in July.

Average daily flow rates at the Valencia WRP have been steadily increasing over the past several years (see Table 4-2). At 7.39 mgd, the average flow in 1991 was approaching the average daily flow design capacity of 7.5 mgd. Monthly average daily flow rates in 1991 ranged from 6.80 mgd in July to 7.86 mgd in December.

TABLE 4-1

SUMMARY OF AVERAGE DAILY FLOW RATES
SAUGUS WATER RECLAMATION PLANT

1988	6.29
1989	7.23
1990	7.40
1991	7.39

(1) Arithmetic mean of monthly average daily flows (n = 12). Monthly average daily flow represents the mean of daily total plant effluent flows.

Combined flows from both the Saugus and the Valencia WRPs averaged 12.6 mgd in 1991. Monthly average daily flows from 1989 to 1991 for both plants combined are listed on Table 4-3, and depicted on Figure 4-5.

Projected Flows

The projected combined flows of the Valencia and Saugus WRPs to the year 2010 are depicted on Figure 4-6. The Growth Management Plan and Air Quality Management Plan, both prepared by the Southern California Association of Governments predicted an increase of approximately 100 percent to the year 2010. Total combined flow from the Saugus WRP and the Valencia WRP is predicted to be approximately 25 mgd by the year 2010.

WASTEWATER QUALITY

Reclaimed Water Quality Requirements

Effluent quality from the Valencia and Saugus WRPs is regulated by the RWQCB-LA. Discharge permits specifying the wastewater quality requirements for effluent discharged to the Santa Clara River have been issued for each plant. Each plant also has a reclamation permit specifying wastewater quality requirements for reclamation of effluent; however, the effluent from the plants is currently not used for reclamation. The requirements in the reclamation permits are essentially the same for both plants.

Depending on the place and purpose of reclaimed water use, the necessary treatment processes and the maximum allowable concentration of constituents vary. These variations are addressed in the reclamation permits. Reclaimed water uses are limited to the uses identified in the permits. The permits specify that reclaimed water used as a source of supply in a nonrestricted recreational impoundment (use subject to the most stringent requirements) must be adequately disinfected, oxidized, coagulated, clarified, filtered wastewater.

The wastewater quality limitations specified in the reclamation permits conform to the reclamation criteria contained in the California Administrative Code, California Department of Health Services (DHS), Title 22, Division 4, Chapter 3, "Reclamation Criteria." In addition, because the groundwater in the Santa Clarita Valley is beneficially used for domestic supply and other purposes, the reclamation permits stipulate that reclaimed water cannot contain trace constituents and other substances in excess of the limits set forth in the current edition of the State Drinking Water Standards (DHS, California Administrative Code, Title 22, Division 4, Chapter 15, "Domestic Water Quality and Monitoring"). The maximum constituent concentration limitations for reclaimed water are listed in Table 4-4.

Silver (mg/L)	<.005	<.005	0.05
Zinc (mg/L)	<.03	.07	5.0
Fluoride (mg/L)	.31	.41	1.6
Radioactivity (pCi/L) (gross alpha + gross beta)	<15	<22	65
Total Identifiable Chlorinated Hydrocarbons (μg/L)	.03	.02	NS
Phenols (mg/L)	<.008	<.005	1.0

(1) Arithmetic mean of effluent analytical data (CSDLAC, Annual Monitoring Report for 1991, 13 March 1992). Frequency of analyses varies among constituents; frequency specified in the Monitoring and Reporting Programs outlined in RWQCB-LA Order Nos. 87-48 and 87-49.

(2) Reclaimed water limitations specified in RWQCB-LA Order No. 89-129 (Valencia WRP) and RWQCB-LA Order No. 89-130 (Saugus WRP). Trace constituent concentration limits obtained from California Department of Health Services, California Administrative Code, Title 22, Division 4, Chapter 15, "Domestic Water Quality and Monitoring" (1989).

NS: Not Specified.
mg/L: milligrams per liter.
MPN/100 ml: Most probable number per 100 milliliters.
NTU: Nephelometric turbidity units.
pCi/L: picocuries per liter.
μg/L: micrograms per liter.

Limitations specified in the discharge permits include the 30-day average biochemical oxygen demand ($BOD_{5,20}$), suspended solids concentrations, and residual chlorine concentrations. The maximum limitations are 20 milligrams per liter (mg/L), 15 mg/L, and 0.1 mg/L, respectively.

Effluent Quality

The quality of effluent from the Saugus and Valencia WRPs has consistently been in compliance with the reclaimed water requirements specified in the reclamation permits. Average concentrations of effluent constituents measured in 1991 for each plant are listed in Table 4-4. Additionally, the tertiary-treated wastewater is "adequately disinfected, oxidized, coagulated, clarified, filtered wastewater" as specified for use of reclaimed water in nonrestricted recreational impoundment, the use subject to the most stringent requirements in the permits.

The effluent from the WRPs continues to comply with the discharge requirements, as well. During 1991, the $BOD_{5,20}$ measured was approximately 8 mg/L for Saugus WRP effluent and 6 mg/L for Valencia WRP effluent. Suspended solids concentration in the effluent averaged less than 2 mg/L for each plant, and residual chlorine concentration remained less than the discharge limitation of 0.1 mg/L.

Potential Irrigation Water Use

Table 4-5 lists guidelines for irrigation water quality standards and compares the effluent water quality from the Valencia and Saugus WRPs to the standards. From the guidelines, it can be seen that, sodium and chloride contents in the effluent are relatively high and may prove toxic to some plants after repeated sprinkler irrigations. If sensitive plants are to be irrigated with the effluent, application of the water by a drip system or surface system should be considered. In addition, ammonia and nitrate concentrations and boron concentrations fall in the "increasing problems" range and could prove toxic to sensitive plants over a period of time. Salinity of the WRP effluent also falls in the "increasing problems" range; however, plants vary widely in tolerance to salinity. Provision of adequate soil drainage will help to alleviate any potential problems due to salinity.

Not listed in Table 4-5 are the adjusted sodium adsorption ratios (SAR) of the effluent. The adjusted SARs are related to carbonate and bicarbonate concentrations and were not available. However, the unadjusted SARs of the effluent from both WRPs are below 10, which classifies them as low-sodium water. In addition, the residual sodium bicarbonate levels of the waters are relatively low. Because the SAR and residual bicarbonate levels are low, the potential for reducing soil drainage is low.

The nutrient composition (nitrogen and phosphorus) of the effluent is actually beneficial for irrigation and may result in a reduction in fertilizer use.

TABLE 4-5

COMPARISON OF EFFLUENT WATER QUALITY TO
IRRIGATION WATER QUALITY STANDARD GUIDELINES (1)

(2) Plants vary in tolerance to salinity.
(3) Adjusted Sodium Adsorpiton Ratio (SAR) is calculated to include the added effects of precipitation or dissolution of calcium and magnesium in soils and is related to CO3 and HC03 concentrations.
(4) For sensitive crops.
(5) Not available.

CHAPTER 5

REGULATORY REQUIREMENTS

Production, discharge, distribution, and use of reclaimed water are subject to federal, state, and local regulations, the primary objectives of which are to protect public health. This chapter describes the regulatory requirements and the methods of administration.

FEDERAL REQUIREMENTS

Two Federal Acts regulate the discharge and use of reclaimed water or wastewater: the Clean Water Act and the Safe Drinking Water Act.

Clean Water Act

Federal requirements impacting the discharge of reclaimed water, or wastewater, (and any other liquid wastes) to "navigable waters" are contained in the 1972 amendments to the Federal Water Pollution Control Act of 1956, commonly known as the Federal Clean Water Act (CWA) (Public Law 92-500). The CWA created the Environmental Protection Agency (EPA) and established the National Pollutant Discharge Elimination System (NPDES), a permit system for discharge of contaminants to navigable waters. NPDES requires that all municipal and industrial dischargers of liquid wastes apply for and obtain a permit prior to initiating discharge.

Safe Drinking Water Act

Federal requirements impacting the use of reclaimed water for groundwater recharge are contained in the 1986 amendments to the Safe Drinking Water Act (SDWA) of 1974 (Public Law 93-523). The SDWA focuses on regulation of drinking water and control of public health risks by establishing and enforcing maximum contaminant levels for various compounds in drinking water. The 1986 amendments also established requirements for protection of groundwater supplies through wellhead protection programs and regulation of underground injection of wastes.

Administration

In the State of California, the administration and enforcement of the NPDES and SDWA programs have been delegated to the State.

STATE REQUIREMENTS

State requirements for production, discharge, distribution, and use of reclaimed water are contained in the California Water Code, Division 7 - Water Quality, Sections 1300 through 13999.16 (Water Code); the California Administrative Code, Title 22 - Social Security, Division 4 - Environmental Health, Chapter 3 - Reclamation Criteria, Sections 60301 through 60475 (Title 22); and the California Administrative Code, Title 17 - Public Health, Chapter 5, Subchapter 1, Group 4 - Drinking Water Supplies, Sections 7583 through 7630 (Title 17). In addition, guidelines for production, distribution, and use of reclaimed water have been prepared or endorsed by State agencies administering the reclaimed water regulations.

Water Code

The Water Code contains requirements for the production, discharge, and use of reclaimed water. The Porter-Cologne Water Quality Control Act (Division 7 of the California Water Code), which was promulgated in 1969, established the State Water Resources Control Board (SWRCB) as the State agency with primary responsibility for the coordination and control of water quality, water pollution, and water rights (Division 7, Chapter 1). Established in 1967, the SWRCB assumed the functions of the former State Water Rights Board and the State Water Quality Control Board, which were abolished.

Nine Regional Water Quality Control Boards (RWQCB) were established to represent the SWRCB regionally and carry out the enforcement of water quality and pollution control measures (Division 7, Chapter 4). In addition, each RWQCB was required to formulate and adopt water quality control plans and establish requirements for waste discharge to waters of the State. In 1972, Chapter 5.5 was added to Division 7 to provide the RWQCBs with the authority to carry out the provisions of the Federal CWA. The RWQCB-Los Angeles has jurisdiction over the Santa Clarita Valley.

Division 7, Chapter 7 - Water Reclamation, was included in the Porter-Cologne Water Quality Control Act in 1969. Subsequent amendments required the California Department of Health Services (DHS) to establish water reclamation criteria, gave the RWQCB the responsibility of prescribing specific water reclamation requirements for water which is used or proposed to be used as reclaimed water, provided for the regulation of injection of waste into the ground, and required the use of reclaimed water, if available, rather than potable water for irrigation of greenbelt areas.

In addition to Division 7, Chapter 7, Sections 1210 through 1212 of the Water Code, added in 1980, focus on the ownership of treated wastewater and require that the owner of a wastewater treatment plant obtain approval from the SWRCB prior to making any change in the point of discharge, place of use, or purpose of use of treated wastewater.

Title 22

In 1975, Title 22 was prepared by the California Department of Health Services (DHS) in accordance with the requirements of Division 7, Chapter 7 of the Water Code. In 1978, Title 22 was revised to conform with the 1977 amendment to the Federal CWA. The requirements of Title 22, as revised in 1978 and again in 1990, regulate production and use of reclaimed water in California today. A copy of Division 4, Chapter 3, "Reclamation Criteria", of Title 22 is included in Appendix B.

Title 22 established three categories of wastewater treatment effluent (reclaimed water):

1. Primary effluent
2. Adequately disinfected, oxidized effluent (commonly called secondary effluent)
3. Adequately disinfected, oxidized, coagulated, clarified, filtered effluent (commonly called tertiary effluent)

Within the second and third categories, criteria for maximum numbers of coliforms within the effluent were established for various reclaimed water uses. Definitions of the wastewater treatment terms are provided in Title 22 in Appendix B.

In addition to reclaimed water uses and treatment requirements, Title 22 addresses sampling and analysis requirements at the treatment plant, preparation of an engineering report prior to production or use of reclaimed water, general treatment design requirements, reliability requirements, and alternative methods of treatment.

Revisions to Title 22 are currently being drafted. It is anticipated that the revisions will expand the list of approved reclaimed water uses primarily for tertiary treated water and address the use of reclaimed water for groundwater recharge in greater detail.

Title 17

Title 17 regulates one aspect of the distribution of reclaimed water. The focus of Title 17 is protection of drinking (potable) water supplies through control of cross-connections with potential contaminants. Examples of potential contaminants to potable water supplies are sewage; nonpotable water supplies such as reclaimed water, irrigation water, and auxiliary water supplies; fire protection systems; and hazardous substances. Title 17, Group 4, Article 2 - Protection of Water System, Table 1 specifies the minimum backflow protection required on the potable water system for situations in which there is potential for contamination to the potable water supply. Reclaimed water is addressed twice as follows:

- An air-gap separation is required on "Premises where the public water system is used to supplement the reclaimed water supply".

- An air-gap separation is required on "Premises where reclaimed water is used and there is no interconnection with the potable water system. A [reduced pressure principle backflow prevention device] may be provided in lieu of an [air gap] if approved by the health agency and water supplier."

An air-gap separation is defined as "a physical break between the supply line and a receiving vessel". A reduced pressure principle backflow prevention device is defined as "a backflow preventer incorporating not less than two check valves, an automatically operated differential relief valve located between the two check valves, a tightly closing shut-off valve on each side of the check valve assembly, and equipped with necessary test cocks for testing".

A copy of Title 17 is contained in Appendix C.

Guidelines

To assist in compliance with Title 22, the DHS has prepared a number of guidelines for production, distribution, and use of reclaimed water. Additionally, for distribution of reclaimed water, DHS recommends use of guidelines prepared by the California-Nevada Section of the American Water Works Association (AWWA). These guidelines are summarized below.

<u>Guideline for the Preparation of an Engineering Report on the Production, Distribution, and Use of Reclaimed Water</u>. According to Title 22, prior to implementation of a water reclamation project (production, distribution, or use) an engineering report must be prepared and submitted to DHS. This guideline, prepared by DHS and dated 10 June 1988, specifies the contents of an engineering report. The report should describe the production process, including the treated (effluent) water quality, the raw water quality, the treatment process, the plant reliability features, the supplemental water supply, the monitoring program, and a contingency plan to prevent distribution of inadequately treated water. The report should include maps of the distribution system and describe how the system will comply with DHS and AWWA guidelines and Title 17. The report should include maps of proposed use areas and should describe the use areas, the types of uses proposed, the people responsible for supervising the uses, the design of the user systems, and the proposed user inspection and monitoring programs. A copy of the guideline is included in Appendix D.

<u>Manual of Cross Connection Control/Procedures and Practices</u>. This manual, dated July 1981, focuses on establishing a cross-connection control program to protect the public against backflow and back-siphonage of contamination. Main elements of the manual include areas where protection is required; causes of backflow; approved backflow preventers; procedures, installation, and certification of

backflow preventers; and water shutoff procedures (for conditions which pose a hazard to the potable water supply). A copy of the manual is included in Appendix D.

Guidelines for the Distribution of Nonpotable Water. These guidelines were prepared by the California-Nevada Section of AWWA. A copy of the guidelines is included in Appendix D. The purpose of these guidelines is to provide guidance for planning, designing, constructing, and operating nonpotable water systems, including reclaimed water systems. Distribution lines, storage and supply, pumping, on-site (user) applications, and system management are discussed. DHS guidelines reference these guidelines.

Guidelines for the Use of Reclaimed Water. These DHS guidelines, dated 10 June 1988, are an expansion of Title 22 and focus on the distribution and use of reclaimed water. They cover general use requirements, such as confinement of reclaimed water to the user site and protection of drinking water supplies, and specific use requirements. The specific uses covered include landscape irrigation, impoundments, and agricultural reuse. Guidelines for worker protection, providing warning signs, limiting access, confining reclaimed water to the site, and scheduling irrigation are provided. A copy of the guidelines are included in Appendix D.

Guidelines for the Use of Reclaimed Water for Construction Purposes. These DHS guidelines, dated 10 June 1988, provide information relating to the production, hauling and use of reclaimed water for construction purposes. Included in the guidelines are controls to be maintained at the treatment plant and during hauling and use. A copy of the guidelines are included in Appendix D.

Administration

In the State of California, reclamation requirements are administered by the SWRCB, the RWQCB, and the DHS. The direct involvement of each agency during a reclamation project is summarized below:

SWRCB

1. Issue loans in accordance with the Water Code.

2. Approve petitions for the change in place and purpose of use of treated wastewater in accordance with the Water Code.

RWQCB

1. Prepare or revise reclamation requirements in accordance with the Water Code.

2. Review and approve engineering report required under Title 22.

3. Review and approve recharge projects using reclaimed water in accordance with the Water Code.

DHS

1. Review and approve engineering report as requested by RWQCB.

2. Review and approve final plans for cross connection control and pipeline separations in accordance with Title 17, and inspect distribution system prior to operation.

3. In conjunction with local health agencies, review and approve final on-site (user) system plans for cross connection control in accordance with Title 17, and inspect system prior to operation.

The DHS has delegated a portion of its administrative duties to local health agencies and becomes more involved at the request of the local health agencies.

LOCAL REQUIREMENTS

Local requirements focus on the distribution and use of reclaimed water and, primarily, the onsite (user) systems, with emphasis on cross-connection control. State regulations and guidelines discussed above are the governing requirements. The County of Los Angeles Department of Health Services establishes more specific requirements for the separation and construction of potable and reclaimed waterlines, guidelines for on-site (user) systems, and identification of reclaimed water facilities. A copy of the County's current guidelines are included in Appendix E.

Administration

Local requirements are administered by the County DHS. The County DHS's direct involvement in a reclaimed water project is as follows:

1. Review as-built drawings of users' potable water system.
2. Perform an onsite survey of the users' water system.
3. Guide users in methods of identifying potable and reclaimed water systems.
4. Review and approve design drawings of users' reclaimed water systems.
5. Inspect user's potable and reclaimed water systems following construction.

CHAPTER 6

MARKET ASSESSMENT FOR RECLAIMED WATER

In this chapter, potential reclaimed water users within the Castaic Lake Water Agency (CLWA) service area are identified. For each potential user, estimates are provided for annual demand, peak monthly demand, peak daily demand, and the hourly distribution of water demand during peak months. Finally, the requirements for potential users to convert their existing water systems to reclaimed water are also discussed.

POTENTIAL USERS

Examination of water consumption records, land use maps, and general plans for the City of Santa Clarita and the County of Los Angeles and discussions with City, County, water purveyor staff and land developers led to identification of existing and future potential users of reclaimed water in the Santa Clarita Valley. The criteria for placement on the initial list of potential reclaimed water users were 1) location within CLWA's service area and 2) demand for reclaimed water of at least 4 acre-feet per year. The initial list of potential users and their reclaimed water demands is included in Appendix A, and the geographical location of the potential users is shown on Plate 1.

The initial list was reduced by defining a service area and eliminating potential users outside the service area. Identification of a service area was based on the location of concentrated demand and the location of users with a demand of at least 200 acre-feet per year. The resulting service area centers on Valencia and encompasses future potential identified users with a demand of 100 acre-feet or more per year. A few potential identified users were excluded due to the difficulty of converting their existing potable water systems to a dual system utilizing reclaimed water for irrigation.

The list was further reduced by evaluating the incremental cost per acre-foot to serve each user. To perform this evaluation, a preliminary system was developed to serve the remaining potential users. The users were then separated into service zones based on geographic location, topography, pressure requirements, and magnitude of demand. The cost to serve each zone was calculated. In the zones with high average costs, the cost of serving each user was determined by multiplying the total cost to serve the zone by a ratio of the user's flow rate compared to the total flow rate for the zone. By dividing the cost to serve each user by the user's annual demand, the cost per acre-foot of water for each user was determined. Potential users whose cost per acre-foot exceeded the average cost per acre-foot for the zone were eliminated.

Table 6-1 presents the final list of users to be served by the reclaimed water system by service (pressure) zone. The locations of the users and the service zones are shown on Plate 2. The user numbers on Plate 2 correspond with the user numbers in Table 6-1.

Potential users with existing water demands (existing users) include Magic Mountain Amusement Park, three golf courses, freeway landscaping, tree farms, AES Placerita Cogeneration Plant, a hospital, the civic center, Eternal Valley Cemetery, and several schools and parks. Potential users with future water demands (future users) include several residential developments, an industrial development and five golf courses.

Since a small portion of Stevenson Ranch (Zone V) falls outside the current CLWA boundary, Zone V will be treated as a separate item throughout this report.

POTENTIAL RECLAIMED WATER DEMAND

Potential annual demands for reclaimed water were estimated from historical water use records for existing users and the proposed irrigated area and expected water use per acre for future users. Demands for reclaimed water are seasonal, with the highest demands occurring during the hot, dry summer months when irrigation requirements are greatest. Peak monthly irrigation demands for existing users were assessed based on available historical data. To approximate peak monthly demand for future users, a peak monthly usage factor for the CLWA service area was calculated by dividing the combined peak monthly demand of the existing users by the combined average monthly demand. The peaking factor calculated was approximately 2.25. Peak monthly demands were then estimated by applying the peak month factor to each future user's average monthly demand.

Peak daily demands and peak hourly demands for existing potential users were either provided by the user, or estimated based on the number of irrigation days per month and the irrigation hours per day. For future potential users, peak daily demands and peak hourly demands were estimated based on irrigation days and hours provided by existing potential users of the same type (i.e. golf course, school, etc.).

The estimated annual, peak monthly, peak daily and peak hourly demands for the reclaimed water users are shown in Table 6-1. The total annual reclaimed water demand is approximately 9,150 acre-feet per year. Total peak monthly demand is estimated to be 1,700 acre-feet, and total peak daily demand is estimated to be 18.0 million gallons or 56 acre-feet.

During the peak month, reclaimed water use is expected to reach its greatest demand between the hours of 12:00 a.m. and 5:00 a.m. Demand during this

period is anticipated to be 2.3 million gallons per hour or 38,500 gallons per minute (gpm). Table 6-2 summarizes the hourly water demand for the system during the peak month.

If service Zone V (a portion of Stevenson Ranch, which is outside the current CLWA service area), is included in the demand, total annual demand is approximately 10,350 acre-feet per year. Peak monthly demand is 1,900 acre-feet, and peak daily demand is 63 acre-feet or 20.5 million gallons. Total hourly water demand for the system during the peak month is estimated to be approximately 45,200 gpm or 2.7 million gallons per hour.

DESIGN CONSIDERATIONS

Reliability of the reclaimed water supply will be important for a majority of potential reclaimed water users identified. AES Placerita, Inc., the only potential industrial user of reclaimed water identified, will require a continuous flow of reclaimed water. Other identified uses are for landscaping or irrigation purposes. Although these users could tolerate short interruptions of reclaimed water service, extended interruptions in service could damage the landscaping or irrigated crops.

CONVERSION REQUIREMENTS

The California Department of Health Services has prepared guidelines for use of reclaimed water (see Appendix D) which are based on the reclamation criteria set forth in Title 22. The guidelines address what steps should be taken in converting water systems to reclaimed water systems. Two primary goals of the guidelines are to prevent potable water systems from being contaminated by reclaimed water and to make the public aware that reclaimed water is being used.

For users with separate irrigation and potable water systems, the primary requirement will be to disconnect the irrigation system from the potable water service and connect it to the reclaimed water service. Reduced pressure principal devices will need to be installed on the potable service immediately downstream of the meter. For those users with irrigation systems that tie to their potable water systems at several locations, the systems will have to be separated. Additionally, all hose-bibs will need to be eliminated from the irrigation systems. Public areas, such as golf courses, parks, and schools, will need to post signs warning the public that reclaimed water is being used for irrigation. Parks, schools, and other users with exposed drinking fountains near landscaped areas will have to provide shields to prevent reclaimed water from coming into contact with the drinking fountains.

The costs of these conversion requirements will be incurred by the users. In general, the costs are anticipated to be relatively low; however, because the cost will depend on meter size and complexity of the irrigation system, costs will vary from user to user.

TABLE 6-2

CHAPTER 7

RECOMMENDED PLAN

The development of the reclaimed water system was based on established planning criteria. These criteria are the concepts and assumptions that ultimately form the service criteria of the system. This chapter presents the criteria for and development of the system, as well as the details of the recommended reclaimed water system.

CRITERIA

Criteria were established for each component of the reclaimed water system, including the reclaimed water supply, the back-up water supply, the reuse pump stations, the storage reservoirs, the distribution system, and the booster pump stations. These criteria, summarized in Table 7-1, are discussed in the following sections.

As mentioned in Chapter 6, because a small portion of Stevenson Ranch (Zone V) currently falls outside the CLWA boundary, Zone V will be treated as a separate item throughout this report.

Reclaimed Water Supply

Reclaimed water will be supplied to the reclaimed water system by the Valencia Water Reclamation Plant (WRP) and the Saugus WRP. Initially, plant production will not be adequate to meet the total demands of the system. However, as potable water demands increase and, consequently, reclaimed water production increases, the water available to meet system demands will also increase. Therefore, it is recommended that construction of the reclaimed water system be phased to utilize the increases in plant production. Projected combined production of the WRPs is depicted on Figure 4-6. Current expansions and modifications planned for the two plants will ultimately increase the combined capacity of the plants from 13.1 million gallons per day (mgd) to 27.6 mgd. It is anticipated that reclaimed water will be constantly available from the plants except during filter backwashing.

The Valencia WRP will ultimately have 14 filters that require backwashing every 24 hours. The backwashing time for each filter will be approximately 20 minutes, and it is anticipated that backwashing will occur throughout the 24-hour period (one filter every 1.7 hours). Each filter will need approximately 5,000 gallons per minute (gpm) for 20 minutes. Therefore, it is anticipated that 14 filters will require a total of 1.4 mgd.

The Saugus WRP currently maintains 4 filters that require backwashing every 24 hours just after midnight. Each filter requires 4,000 gpm for 20 minutes. Since the effluent flow is equalized, it is anticipated that the backwashing schedule could be revised so that backwashing is spread throughout the 24 hour period.

Reuse Pump Stations

A reuse pump station will be located at each WRP to provide reclaimed water to the distribution system. Reuse pump station capacity is dependent upon plant production and effluent flow patterns, as well as reclaimed water demands. The Saugus WRP has an ultimate dry weather, average daily flow capacity of 5.6 mgd which will limit pump station capacity at the Saugus WRP to approximately 4,000 gpm based on an equalized effluent flow. Future planned modifications to the Valencia WRP will equalize the effluent flows and increase the capacity to 22 mgd. The ultimate pump station capacity at the Valencia WRP will be limited to approximately 15,000 gpm.

Proposed storage capacity will provide for reductions in the required reuse pump station capacity by allowing peak hour demands to be met with a combination of pumped water and water from storage reservoirs. The reuse pump stations will be controlled by water surface elevations in the storage reservoirs.

Storage Reservoirs

The recommended storage capacity to be provided for the reclaimed water system is equivalent to approximately 75 percent of the peak day demand. Reservoir elevations will be dictated by the required system and delivery pressures as discussed later in this chapter.

Distribution System

Distribution system design is dependent upon flow, velocity, and pressure criteria. The distribution system will be sized to handle the peak hour demands. High velocities, which may impair pipeline useful life and increase energy requirements to deliver water, are not desirable. Maximum design flow velocity in the system will be 6 feet per second.

Two pressure criteria were considered in the planning of the system. Defined as the pressure at any point within the distribution system, system pressure is dependent upon reservoir levels, reclaimed water demands and pumping conditions. The maximum system pressure will be 185 pounds per square inch (psi). Delivery pressure refers to the pressure at which reclaimed water is delivered to the users. Optimum delivery pressure ranges from 55 psi to 150 psi.

Booster Pump Stations

The function of the booster pump stations is to boost the system pressure from a lower zone to a higher zone. The stations should be designed to meet the peak day demand of the higher zones. They should also be sized large enough to operate during off-peak electrical hours. The criteria for system pressure and delivery pressure discussed in the previous section also apply to design of the booster pump stations.

TABLE 7-1

SUMMARY OF RECLAIMED WATER SYSTEM CRITERIA

SYSTEM COMPONENTS	CRITERIA
Reclaimed Water Supply	• Projected plant production determines construction phasing. • Assume equalized effluent flow at both plants.
Reuse Pump Stations	• Saugus WRP pump station limited to 4,000 gpm. • Valencia WRP pump station limited to 15,000 gpm. • Pumps will operate during demand periods.
Storage Reservoirs	• Provide storage for approximately 75% of the peak day demand. • Reservoir elevations should be adequate to provide optimum delivery pressures to most users.
Distribution System	• Size to meet the peak hour demands. • Maximum design velocity is 6 feet per second. • Maximum system pressure: 185 psi. • Optimum delivery pressure range: 55 to 150 psi. • All buried piping is "purple" high-pressure PVC (currently 24-inch diameter is maximum available).
Booster Pump Stations	• Size for peak day demands. • Size to operate during off-peak electrical hours in order to minimize energy costs.

DEVELOPMENT

The development of the reclaimed water system was based on the above criteria and the cost of serving the previously identified potential users. As discussed in Chapter 6, cost per acre-foot of reclaimed water for each user was determined. Potential users whose cost per acre-foot exceeded the average cost per acre-foot for their zone were eliminated. The distribution system was then modified to effectively serve the remaining users. The result is the recommended reclaimed water system. Plate 2 shows the location of the recommended reclaimed water users and service zones.

COMPONENTS OF THE PLAN

Serving approximately 75 users, the recommended reclaimed water system master plan is divided into six service zones. Zone V, a portion of Stevenson Ranch, is outside CLWA's boundaries and will be treated separately. Each of the zones will contain storage reservoirs, distribution system piping, and booster pump stations. The reuse pump stations will be located at the reclaimed water supply. The proposed layout of the reclaimed water system is shown on Plate 3. Locations of Zone IV facilities were not determined due to the uncertainty of future developments. Flow and storage information for each of the zones is presented in Table 7-2.

TABLE 7-2

FLOW AND STORAGE DATA

SERVICE ZONE	PEAK DAY DEMAND (mgd)	PEAK HOUR DEMAND (gpm)	STORAGE VOLUME (MG)	REQUIRED REUSE PUMP (1) STATION CAPACITY (gpm)
I	8.80	18,264	6.60	6111
II	1.25	3,068	1.00	868
III	6.21	12,370	4.60	4312
IV	0.90	2,327	0.70	625
VI	0.87	2,407	0.70	604
TOTAL	18.03	38,436	13.60	12,520
STEVENSON RANCH (OUTSIDE CLWA BOUNDARIES)				
V	2.45	6,801	1.9	1,700
GRAND TOTAL	20.48	45,237	15.50	14,220

(1) Assumes Reuse Pump Stations operate 24 hours per day.

Reclaimed Water Supply

Reclaimed water will be supplied to the reclaimed water system from the Valencia and Saugus WRPs. Treated wastewater will be diverted from the chlorine contact tanks at each WRP via overflow weirs and will flow to the reclaimed water pump station. The total system demand for reclaimed water is approximately 9,150 acre-feet per year, most of which will be used from May through October (10,350 acre feet per year if Service Zone V is included). It is anticipated that reclaimed water will be constantly available from both the WRPs except during filter backwashing.

Reuse Pump Stations

Reclaimed water pump stations will be located near the chlorine contact tanks at the Valencia and Saugus WRPs and will be used to transport the reclaimed water to the storage reservoirs in each zone. Assuming constant flow rate and total daily flow equivalent to the peak day demand, the recommended capacities of the reuse pump stations are 10,000 gallons per minute (gpm) at the Valencia WRP and 3,000 gpm at the Saugus WRP. If Zone V is implemented the recommended capacity of the reuse pump station at the Valencia WRP is 12,000 gpm. Table 7-3 indicates that no reclaimed water will be available at the Saugus WRP during filter backwashing while 10,000 gpm will be available at the Valencia WRP.

TABLE 7-3

AVAILABLE RECLAIMED WATER DURING BACKWASH

PLANT	REUSE PUMP STATION CAPACITY (GPM) (1)	TOTAL AVAILABLE PLANT EFFLUENT FLOW (GPM)	REQUIRED BACKWASH FLOW PER FILTER (GPM)	AVAILABLE RECLAIMED WATER DURING BACKWASH (GPM)
VALENCIA WRP (2)	12,000	15,000	5,000	10,000
SAUGUS WRP (3)	3,000	4,000	4,000	0
TOTAL	15,000	19,000	9,000	10,000

(1) 12,000 gpm at VWRP includes Zone V flow requirements.
(2) 14 filters backwashed throughout the day (20 minutes per filter every 1.7 hours)
(3) 4 filters backwashed throughout the day (20 minutes per filter every 6 hours)

Storage Reservoirs

The recommended plan includes construction of nine reclaimed water storage reservoirs (including reservoir number 8 for Zone V). Each zone will have one reservoir with the exception of Zone I which will have three and Zone III which will have two. The storage capacity in each zone will be equal to 75 percent of the peak day demand. The reservoirs are assumed to be above-ground steel tanks and will range in size from 0.7 million gallons to 3.1 million gallons. Total storage capacity for the system is 13.6 million gallons (15.5 million gallons including Zone V). Reclaimed water entering and exiting the storage reservoirs will be controlled by two-way flow altitude valves. Storage reservoir locations are shown on Plate 3, and reservoir capacities are listed in Table 7-4. A location for the Zone IV reservoir was not determined due to uncertainty of future developments. The reservoir elevations are determined by the system and delivery pressures and are also listed in Table 7-4.

Distribution System

The proposed pipeline routes for the reclaimed water system are shown on Plate 3. The routes are located along existing public rights-of-way, where possible, to minimize the costs of acquiring pipeline easements. The distribution system, excluding Zone V, consists of approximately 277,000 lineal feet of pipe ranging from 6 to 36 inches in diameter. This includes a reasonable estimate of pipe required for Zone IV. If Zone V is included, the total lineal feet of pipe to be provided increases to 300,000. The lengths and diameters of the pipeline segments for each zone are presented in Table 7-5. High pressure polyvinyl chloride (PVC) pipe is the primary pipe type used throughout the system. In addition, steel pipe is required at bridge crossings and ductile iron pipe at pump stations and reservoirs.

TABLE 7-5

PIPELINE DIAMETERS AND LENGTHS

Total (1)			300,025

(1) Total of Zones I - VI

The proposed system crosses the Santa Clara River in four locations: Bouquet Canyon Road, McBean Parkway, The Old Road, and Southern Pacific's abandoned Railroad Bridge. It is proposed that the pipelines be supported from the existing bridge crossings. It is also proposed that the pipelines be supported from two bridge crossings over Interstate 5 at McBean Parkway and Valencia Boulevard. Air release valves will be installed at the high points of the distribution system to remove trapped air, and blow off valves will be installed at the low points of the distribution system to remove sediment.

Booster Pump Stations

Included in the recommended plan are seven booster pump stations located throughout the distribution system (including Booster Pump No. 6 for Zone V). The seven booster pump stations are at the head of each service zone to increase system and delivery pressures. Booster pump station capacities range from 1,200 to 4,100 gpm. Booster pump station locations are shown on Plate 3, and capacities and operating hours are listed in Table 7-6. A location for the Zone IV booster pump station was not determined due to the uncertainty of future developments.

Users with pressures less than 55 psi may require independent booster pump stations. It is anticipated that a booster pump station will be required for the North River Golf Course which represents a demand of approximately 600 acre-feet per year. It is assumed that North River will provide its own booster pump station.

COST ESTIMATES

Table 7-7 presents criteria used in estimating costs. Cost estimates presented in this report are order-of-magnitude type estimates expected to be accurate within $\pm$ 25 percent. The cost estimates were developed from general cost curves, information from suppliers, other studies, and Kennedy/Jenks Consultants' previous experience. Reuse pump station costs are for modular pump stations and include costs for construction of the wet wells, installation of pertinent piping and telemetry, provision of back-up pumps, connection to the power source, and testing of the pumps. Incorporated into the reservoir construction costs are the costs for grading, materials, and construction. Pipeline construction costs assume in-street construction with a moderate degree of utility crossings and include items such as valves, traffic control and road resurfacing. Booster pump station costs are for modular stations and consist of costs for all materials, equipment, construction and testing, similar to the modular reuse pump stations costs discussed above. The Santa Clara River and Interstate 5 crossings assume supporting of the pipelines on the bridges. System flushing and testing costs assume that approximately 1,000 feet of pipe will be tested per day. Not included in the cost estimate are pipeline easements and pump station/reservoir property costs.

TABLE 7-6

BOOSTER PUMP STATION CAPACITIES

BOOSTER PUMP STATION NUMBER	ZONES SERVED	OPERATING HOURS (HRS./DAY)	CAPACITY (gpm)
1	I	9	3,500
2	I	10	4,100
3	III, IV, V, VI	24	3,740
4	III, IV, V, VI	24	3,500
5	IV	12	1,250
7	VI	12	1,200
STEVENSON RANCH (OUTSIDE CLWA BOUNDARIES)			
6	V	18	2,270

The estimated construction cost of the reclaimed water system is approximately $30 million (1993 dollars) not including Zone V, and approximately $33 million including Zone V. Table 7-8 summarizes these costs. Construction costs contain a 15 percent mark-up for contractor overhead and profit.

The cost estimates were developed to provide a reference for financial planning. The actual construction cost and project cost will depend on the final project scope, the schedule for construction, and market conditions at the time of construction. Feasibility of the project and funding needs must be considered and reviewed thoroughly in order to select the proper option and to provide adequate funding.

TABLE 7-7

COST CRITERIA (1)

COMPONENT	COST CRITERIA
Reuse Pump Stations	Cost curve based on historical data (2)
Reservoirs (3)	50¢/gal.
Pipelines (4)	
36-inch Ductile Iron	$108/ft.
16-inch Ductile Iron	$48/ft.
24-inch PVC	$90/ft.
20-inch PVC	$75/ft.
18-inch PVC	$68/ft.
16-inch PVC	$60/ft.
14-inch PVC	$53/ft.
12-inch PVC	$45/ft.
10-inch PVC	$38/ft.
8-inch PVC	$30/ft.
6-inch PVC	$23/ft.
Santa Clara River Crossings (5)	
Bouquet Canyon Rd. Bridge (500'-16")	$80/ft.
McBean Parkway Bridge (600'-12")	$60/ft.
Old Road Bridge (620'-24")	$120/ft.
S.P. Railroad Bridge (205'-16")	$80/ft.
Interstate 5 Bridge Crossings (5)	
Valencia Boulevard Bridge (500' - 12")	$60/ft.
McBean Parkway Bridge (500' - 12")	$60/ft.
Booster Pump Stations	Cost curve based on historical data (2)
System Flushing and Testing (6)	$1/ft.

(1) All figures represent installed costs.
(2) See Figure B-3 in Appendix F.
(3) Includes tank, foundation, appurtenances, excavation, paving, fencing, landscaping and telemetry.
(4) Assume $3.75/diameter-inch for PVC and $3.00/diameter-inch for ductile iron.
(5) Assume steel pipe at $5/diameter-inch.
(6) Assumes 1,000 ft./day at $1,000/day.

TABLE 7-8

PRELIMINARY COST ESTIMATE

CHAPTER 8

ENVIRONMENTAL CONSIDERATIONS

Effluent from the Valencia Water Reclamation Plant (WRP) and the Saugus WRP currently discharges to the Santa Clara River, supplementing the natural ephemeral flows. Because effluent discharges from the WRPs flow through riparian habitat of two endangered species, assessment of the potential impact of a reclamation project on the habitat and development of mitigation measures are important. This chapter provides a brief discussion of Santa Clara River hydrology, the riparian habitat, the endangered species, and potential impacts of the proposed reclaimed water project on stream flows.

SANTA CLARA RIVER HYDROLOGY

Beginning in the San Gabriel Mountains east of Santa Clarita, the Santa Clara River flows approximately 84 miles westward to the Pacific Ocean. Surface flow typically occurs during the rainy season or snow-melt season; however, portions of the river have surface flow year round. Natural "rising water", reclaimed water, agricultural runoff, and other miscellaneous flows contribute to this year-round flow.

In the Santa Clarita Valley, the Valencia and Saugus WRPs contribute to the river flow. Typically, there is year-round surface flow in the river from the Valencia WRP to the vicinity of Piru. In summer months, it appears that the effluent from the plants comprises a significant portion of the river flow. An analysis was performed to estimate the current effluent contribution from the two WRPs to the total average stream flow on a monthly basis.

The analysis was based on 40 years of stream flow data for Stream Gauge F92-R from the County of Los Angeles and effluent flow data for the Saugus and Valencia WRPs from the County Sanitation Districts of Los Angeles County (CSDLAC). Stream gauge F92-R is located on the Old Road Bridge. Based on the available data, WRP effluent flow contributes more than 90 percent of the total river flow from July through November. Table 8-1 summarizes the analysis.

RIPARIAN HABITAT

One of the few major drainages of the San Gabriel Mountains that remains virtually unchannelized, the Santa Clara River includes freshwater marshes and woodland communities. These habitat types are rapidly disappearing and are important to the local wildlife, according to the "Draft Environmental Impact Report for the Draft Castaic Corridor Plan" (EIR) (State Clearinghouse No. 87042907) prepared by Envicom Corporation for Los Angeles County Department of Regional Planning in 1988. (This EIR is the basis for much of the discussion in this chapter.) The river plain from the vicinity of the Valencia WRP downstream to the Ventura/Los Angeles

County line has been declared a Significant Ecological Area (SEA) by Los Angeles County. The primary reason is that it provides habitat for two federally endangered animal species: the unarmored threespine stickleback (fish) and the least bell's vireo (bird).

The portion of the river from Interstate 5 downstream to San Martinez Grande Canyon has been 'declared an Essential Habitat Area (EHA) for the stickleback, and the entire river upstream of San Martinez Grande Canyon is considered to be an Essential Management Area (EMA) for the stickleback. Being considered an EMA means that the river must be managed in such a way that it will provide water of sufficient quantity and quality to support the EHA of the stickleback. In addition, the portion of the river from Castaic Junction to Piru Creek is proposed as a critical habitat for the least bells vireo.

ENDANGERED SPECIES

The Santa Clara River provides habitat to a number of sensitive animal species according to the County's 1988 EIR; however, the following discussion focuses on the two species classified as endangered under the Federal Endangered Species Act: the unarmored threespine stickleback and the least bell's vireo.

Unarmored Threespine Stickleback (G. a. williamsoni)

The unarmored threespine stickleback (UTS) is a federally endangered species, as well as a California endangered species. In the past, the UTS was found in the Los Angeles, San Gabriel, Santa Ana, Santa Clara, and Santa Maria river systems. Populations now remain only in the Santa Clara River and Santa Maria River systems. Santa Clara River system populations exist in Soledad Canyon, San Francisquito Canyon, and in the River between Interstate 5 and San Martinez Grande Canyon.

The UTS has been studied in recent years. A recovery plan for the species was prepared by the U.S. Fish and Wildlife in 1985. The UTS is a tiny fish (approximately 2 inches long) that habitates in streams. It reproduces in pools and shallow backwaters along the streams. Flow velocity and water temperature are important parameters in the maintenance of a suitable habitat.

Concerns addressed in the recovery plan include interbreeding with the unarmored subspecies and introduction of competitors and predators into the habitat. Continuous flow in the river can cause either of these concerns to be realized. The armored stickleback, which are not endangered, are found in the eastern end of the Santa Clarita Valley. The concern is that, if flow becomes continuous between the armored stickleback and UTS habitats, the subspecies may interbreed and the unique unarmored subspecies may be lost. As for the competitors and predators, the concern is that if flow becomes continuous between the competitors or predators and the UTS, the competitors or predators may be introduced into the UTS habitat.

Least Bell's Vireo (Vireo belli pusillus)

The least bell's vireo (LBV) is a federally endangered species, as well as a California endangered species. The LBV is a summer resident of the Santa Clara River habitat. It has been found in San Francisquito Canyon and along the Santa Clara River east of Piru. The LBV nests in the thick vegetation along the river in areas dominated by willows. The species was found in the Central Valley in the past but currently exists only south of the Tehachapi mountains. The decline of the species has been primarily due to loss of riparian habitat and cowbird parasitism.

IMPACT OF THE RECLAIMED WATER SYSTEM ON STREAM FLOWS

Because effluent from the Saugus and Valencia WRP's comprises a majority of the total flow in the Santa Clara River during summer months, it is important to consider the impact of a reclaimed water system on the total river flow. In the future, the Santa Clara River will be impacted by the Saugus and Valencia WRPs with or without implementation of a reclaimed water system. If the proposed reclaimed water system is not implemented and the effluent from the Saugus and Valencia WRPs continues to be discharged to the river, average annual discharges to the river are projected to increase by 95 percent by the year 2010. Discharges in 1990/1991 averaged about 12.60 million gallons per day (mgd) annually; 2010 discharges (if the reclaimed water system is not implemented) are projected to average 24.6 mgd annually.

If the reclaimed water systems is implemented (including Zone V-Stevenson Ranch outside CLWA boundaries), average annual discharges to the river are projected to increase by approximately 20 percent; however, discharges are anticipated to decrease from May through September and increase from October through April due to the expected reclaimed water use pattern (see Chapter 10). A comparison of the current (1990/1991) stream flows versus the projected 2010 stream flows, including WRP discharges and assuming implementation of the reclaimed water system, is presented on Figure 8-1 and in Table 8-1. The difference in current versus 2010 flows are greatest in July and December. In 2010, average stream flow in July is anticipated to be 8.04 mgd less than current average July flows, and average stream flow in December is anticipated to be 10.58 mgd more than current average December flows.

The impacts on the river habitat and the endangered species are difficult to determine. The following chapter presents one possible approach to mitigating reduced summer flows.

CHAPTER 9

SEASONAL STORAGE

As discussed in the previous chapter, effluent from both the Saugus and Valencia Water Reclamation Plants (WRP) is currently discharged to the Santa Clara River. Implementation of the proposed reclaimed water system will decrease the effluent discharged to the river during the dry season. Concepts for a seasonal storage reservoir as a means of mitigating potential impacts to the river flows are discussed in this chapter. Discussions on reclaimed water demand versus supply, reservoir siting, capacity and operation, facility requirements, and preliminary cost estimates are included.

RECLAIMED WATER DEMAND VERSUS SUPPLY

In 1991, approximately 12.7 million gallons per day (mgd) was discharged to the river during the peak irrigation month (July). In the year 2010, the projected combined effluent flow from the WRPs for the peak irrigation month (July) is 25.1 mgd. Peak day demands for the reclaimed water system (user demands) are anticipated to total 20.5 mgd. These demands leave approximately 4.6 mgd to be discharged to the river during the peak irrigation month in the year 2010. Projected reclaimed water demand and supply available from the WRPs are shown on Figure 9-1 and in Table 9-1. The reclaimed water demand pattern was estimated based on evapotranspiration data from the Department of Water Resources.

In 1988, Castaic Lake Water Agency (CLWA) approved a programmatic Environmental Impact Report that included a reclaimed water element. The minimum effluent discharged to the river in 1988 was 9.72 mgd for the month of March. For purposes of this report, in order to conservatively estimate reservoir capacity and costs, a river flow of 9.72 mgd was selected as a "minimum target flow." This flow was selected on the basis of the 1988 EIR's declaration of "no impact." However, it is recommended that an evaluation be performed to determine the minimum flow at which adverse impacts are expected.

As shown in Table 9-1, reclaimed water supply in excess of user demands is less than 9.72 mgd from June through August. Total river flow includes excess reclaimed water supply and natural river flows. To determine the average natural river flow, 34 years of stream gauge data for the Lang Station near Oak Spring Canyon and 40 years of stream gauge data were obtained for the Old Road Bridge Station. It should be noted that the periods of record for the gauges do not encompass the same years. For the Lang Station, it appears that the maximum natural flow occurs in April and averages approximately 5.24 mgd. The average annual natural flow is approximately 3.4 mgd. For the Old Road Bridge Station, it

appears that the maximum natural flow occurs in March and averages approximately 50.25 mgd. The average annual natural flow is approximately 10.34 mgd. To calculate the maximum and average natural flows at the Old Road Bridge Station, Saugus WRP flows were deducted from the stream gauge data.

TABLE 9-1

PROJECTED RECLAIMED WATER DEMAND VS. SUPPLY FOR YEAR 2010

MONTH	WRP SUPPLY (MGD)	USER DEMAND (MGD)	EXCESS SUPPLY (MGD)
January	23.86	1.74	22.12
February	24.11	3.03	21.08
March	24.11	5.03	19.08
April	23.62	10.13	13.49
May	23.86	12.39	11.47
June	25.09	16.50	8.59
July	25.09	20.48	4.61
August	25.58	17.16	8.42
September	25.09	13.88	11.21
October	25.09	6.12	18.97
November	24.85	2.63	22.22
December	24.85	1.74	23.11
Average	**24.60**	**9.24**	**15.36**

Figure 9-2 depicts the relationship between the natural river flow at each gaging station, the 9.72 mgd target flow in the river, and the total available supply (excess supply from the WRPs plus the natural river flow). As shown, natural river flow combined with excess supply from the WRPs meets the minimum target flow of 9.72 mgd in the month of June. However, flow in the river in July and August does not meet the minimum target flow.

RESERVOIR SITING

Topographic maps of the Santa Clarita Valley were reviewed for possible reservoir sites. Several sites were selected based on topography. All but two of these sites were eliminated based on proximity to existing and future developments, to existing faults, or to the proposed reclaimed water system. The remaining two reservoir sites are shown on Figures 9-3 and 9-4. The Charlie Canyon site can provide up to 6,300 acre-feet of additional water storage. The Oak Spring Canyon site can provide up to 12,500 acre-feet of additional water storage.

RESERVOIR CAPACITY

Reservoir capacity should provide storage for maintenance of the minimum target river flow as well as for evapotranspiration (evaporation and transpiration). The reservoir should also have a minimum pool which can equal up to one third of the total capacity of the reservoir. As shown on Figure 9-2, excess reclaimed water supply from the WRPs combined with natural river flow does not meet the 9.72 mgd minimum target flow in the months of July and August. The analysis is presented numerically in Tables 9-2 and 9-3 for the Charlie Canyon site and Oak Spring Canyon site, respectively. Natural river flow projections are based on the Old Road Bridge Station for the Charlie Canyon site and the Lang Station for the Oak Spring Canyon site.

To meet the target flow, release flows of 3.97 and 0.32 mgd are required for the months of July and August, respectively, for the Charlie Canyon site. Release flows of 4.31 and 0.57 mgd are required for the months of July and August, respectively, for the Oak Spring Canyon site. These requirements equate to storage volumes of 410 acre-feet for the Charlie Canyon site and 465 acre-feet for the Oak Spring Canyon site. The differences in release flows for the two sites is attributed to the differences in natural river flow gaged at each site. The Old Road Bridge Station is downstream of the Lang Station. Tributary streams and local drainage between the Lang Station and the Old Road Bridge Station contribute flow resulting in higher natural flows at the Old Road Bridge Station.

Evapotranspiration quantities are taken from Department of Water Resources data, which estimates approximately 52.8 inches or 4.4 feet per year of water is lost due to evaporation and transpiration. The minimum reservoir capacity requirements for the two alternatives are shown below:

Storage Category	Charlie Canyon (acre-feet)	Oak Spring Canyon (acre-feet)
Release Flow	410	465
Evapotranspiration	165	265
Minimum Pool	335	385
Minimum Reservoir Capacity Requirements	910	1,115

RESERVOIR OPERATION

The two reservoir sites selected allow for two approaches to mitigate potential impacts on the river habitat. The Charlie Canyon site would allow excess supply from the WRPs to be discharged directly to the Santa Clara River. Water from the reservoir released to Castaic Creek would supplement the supply from the WRPs during July and August. The target flow for the river would be maintained

07694

beginning at the confluence of Castaic Creek and the Santa Clara River. The Oak Spring Canyon site would allow for pumping of excess supply from the WRPs up to Oak Spring Canyon where it would be discharged and supplemented with water from the reservoir released to Oak Spring Creek. The minimum target flow for the river would be maintained beginning at the confluence of Oak Spring Creek and the Santa Clara River.

Reservoir operation would generally follow this pattern:

- Deliver reclaimed water to reservoir for 6 months each year (October through March).
- Release water from reservoir for 2 months each year (July and August).

A seasonal summary of operations for the two reservoir sites are provided in Tables 9-2 and 9-3. The two tables are similar except for two distinctions. First, the natural river flow for the two tables is different: the Old Road Bridge Station was used for the Charlie Canyon Site and the Lang Station was used for the Oak Spring Canyon site. Second, in the Charlie Canyon alternative, excess flows from the WRPs will be released directly to the river, maintaining the 9.72 mgd target flow downstream of the WRPs. In the Oak Spring Canyon alternative, the 9.72 mgd will be maintained upstream of the WRPs near Oak Spring Canyon. This requires pumping the excess flow from the WRPs to discharge at a location just downstream of the potential reservoir site. This alternative will provide water to the Santa Clara River not only downstream of the WRPs but also upstream of the WRPs near Sand Canyon Road. A target flow of 9.72 mgd will be maintained where an average flow of 3.4 mgd currently exists.

To estimate the required reclaimed water supply to the reservoir, the collection of local runoff was also considered. Runoff was estimated from stream flow data and precipitation data for gages maintained near the proposed reservoir sites. Because the drainage areas for Charlie Canyon and Oak Spring Canyon are relatively small (5,000 acres and 2,400 acres, respectively), only stream gauges with similar drainage areas were considered. This criterion eliminated all but three gages. The remaining three gages were located in the Charlie Canyon area and had periods of records of only four to five years. To determine how these years compared to the long term average, precipitation data with long periods of record were obtained from rain gauges maintained near the proposed reservoir sites. Rainfall data for the years corresponding to the stream gauge data were compared to the long term rainfall average. The comparison showed that the long term average annual rainfall was 35 percent higher in the Charlie Canyon area than the short term average for the stream gauge period of record and 11 percent higher in the Oak Spring Canyon area. The average runoff quantities recorded by the stream gauges were increased by these percentages.

Because the three stream gauges were in the Charlie Canyon area, to "transfer" the data to the Oak Spring Canyon area required comparing rainfall and soil types. Average annual rainfall in the Oak Spring Canyon area is 29 percent higher than average annual rainfall in the Charlie Canyon area. However, infiltration rates in the Oak Spring Canyon area are about two times higher than infiltration rates in the Charlie Canyon area. By applying the appropriate factors to the unit runoff for the stream gauges, Charlie Canyon unit runoff was estimated to be 0.053 acre-foot/year per acre of drainage area and Oak Spring Canyon unit runoff was estimated to be 0.027 acre-foot/year per acre of drainage area. These factors correspond to an annual runoff of 265 acre-foot/year for Charlie Canyon and 65 acre-foot/year for Oak Spring Canyon.

Taking local runoff into consideration, the average annual reclaimed water requirements for the reservoir are estimated to be as follows:

Category	Charlie Canyon (acre-feet)	Oak Spring Canyon (acre-feet)
Release Flow	410	465
Evapotranspiration	165	265
Runoff	-265	-65
Average Annual Reclaimed Water Requirement	310	665

Assuming a 6-month pumping time (October through March), Charlie Canyon reservoir would require a reclaimed water flow of 0.56 mgd and Oak Spring Canyon reservoir would require a flow of 1.20 mgd.

FACILITY REQUIREMENTS

To determine whether the reclaimed water system recommended in Chapter 7 could accommodate the additional flows to the seasonal storage reservoirs, hydraulic modeling was performed for both the Charlie Canyon and Oak Spring Canyon sites. The basis for the following analyses is the proposed reclaimed water system including Zone V, which is currently outside the CLWA's boundary.

Charlie Canyon

As shown on Table 9-3, a flow of 0.56 mgd from October through March would supply the Charlie Canyon reservoir. Because Charlie Canyon is north of the Valencia WRP, the distribution lines north of the Valencia WRP were evaluated to determine whether increased pipeline diameters would be necessary to accommodate the additional flow to the reservoir. Since Booster Pump Station No. 2 is above the reservoir site, increasing the capacity of the booster station would not be required.

The system north of the Valencia WRP is sized for a peak day demand of 3.69 mgd which occurs in July. Because flow to the reservoir does not occur in July, the month with the highest user demand when additional flow is supplying the reservoir was evaluated. From October through March, October has the highest user demand of 1.1 mgd for users north of the Valencia WRP. Adding an additional flow of 0.56 mgd to supply the reservoir results in a total flow requirement of 1.66 mgd. This flow is less than peak day demand upon which the distribution lines were sized. Therefore, modifications to the proposed reclaimed water system do not appear necessary. However, approximately 7,500 feet of 8-inch polyvinyl chloride (PVC) pipeline would be required from a connection point at Tapia Canyon Road to the reservoir. Figure 9-3 shows the proposed alignment.

Oak Spring Canyon

The reservoir in Oak Spring Canyon would require pumping of reclaimed water not only to supply the reservoir but also to maintain river flow upstream of the WRPs. In addition, because the reservoir site is located at the extreme end of the reclaimed water system, the distribution system would require extensive modifications.

Although user demands in August (17.41 mgd) are less than the peak user demands which occur in July (20.48 mgd), hydraulic modeling was performed for the month of August because the WRP supply is the greatest in August, and it is anticipated that excess supply from the WRPs would be pumped through the distribution system to maintain a minimum discharge to the river upstream of the WRPs. Therefore, because the proposed reclaimed water system was designed for a peak day demand of 20.48 mgd and it is anticipated that a demand of 25.58 mgd (projected peak day supply, which occurs in August) would be required through the distribution system, upgrading the system to accommodate the additional flows would involve the following:

- Upgrade Valencia WRP from 12,000 gpm to 15,200 gpm.
- Upgrade Saugus WRP from 3,000 gpm to 3,800 gpm.
- Upgrade BPS #4 from 3,500 gpm to 8,200 gpm.
- Upgrade BPS #5 from 1,250 gpm to 6,375 gpm.
- Upgrade 97,975 feet of pipe.
- Parallel 26,900 feet of pipe.

Approximately 22,500 feet of 10 and 20 inch pipe will be required between the point of connection to the reclaimed water system at Via Princessa and the reservoir. Additionally, an 870-gpm booster pump station located on Oak Spring Canyon Road will be required to pump water to the reservoir. Figures 9-4 and 9-5 show the upgraded system for the Oak Spring Canyon alternative.

PRELIMINARY COST ESTIMATE

Preliminary cost estimates for the two alternative reservoir sites including distribution system requirements, are provided in Table 9-4. Reservoir costs assume an earth-fill dam. As shown, the Charlie Canyon reservoir is estimated to cost approximately $5.1 million (1993 dollars). The Oak Spring Canyon reservoir is estimated to cost approximately $14.4 million (1993 dollars). These estimates are conceptual, and it is recommended that a more detailed feasibility study of these reservoir alternatives be performed.

Other investigations and studies that should be conducted in order to determine the feasibility of the reservoirs and to estimate the costs more accurately include the following:

- Environmental studies
- Watershed investigations
- Hydrogeologic studies
- Geotechnical investigations
- Seismic investigations

In addition, the retail water purveyors have wells along the river that draw water from the alluvial aquifer, downstream of the reclamation plant discharges. If reclaimed water is released to the river upstream of these wells, the State Department of Health Services may consider the water to be a potential source of waterborne contamination for the wells and may require disinfection under the Surface Water Treatment Rule, which applies to groundwater under the influence of surface water, or the anticipated Groundwater Disinfection Rule. The potential impact on the retail water purveyors should be evaluated.

CHAPTER 10

IMPLEMENTATION PLAN

In the previous chapters, a reclaimed water system master plan for the Castaic Lake Water Agency (CLWA) service area was developed. This chapter presents a plan for implementing the recommended system. The discussion focuses on the implementation plan, permit requirements, other institutional issues, and the implementation schedule.

IMPLEMENTATION PLAN

Phased implementation of the reclaimed water system is recommended for the following reasons:

- A number of the potential reclaimed water users are future users that do not yet need reclaimed water.
- The current combined flow of the Valencia and Saugus Water Reclamation Plants (WRPs) is not adequate to meet the total demands of the potential reclaimed water users.
- Capital requirements would be spread over CLWA's current planning period.

The reclaimed water system is divided into implementation phases based primarily on service zone boundaries. Zones I and III are further divided based on location and status of potential users (i.e., existing versus future). Zone I is divided into three subzones: IA, IB, and IC. Zone III is divided into two subzones: IIIA and IIIB.

The implementation phases are prioritized based on the status of the users (existing or future), the anticipated construction schedule of future users, and the proximity of the users to the Valencia and Saugus WRPs. It is recommended that the reclaimed water system be implemented as shown in Table 10-1. Included in the priority list is Zone V, a small portion of Stevenson Ranch that is currently outside CLWA's boundary. Zone V is considered a separate phase which could be implemented if Zone V is annexed into CLWA's service area. Utilizing the criteria used to prioritize the other phases, Zone V would most likely be implemented following Phase 8. Implementation of the seasonal storage reservoir would most likely occur after the year 2000. Construction of the reservoir can proceed concurrently with construction of the distribution system.

The phasing sequence shown in Table 10-1 is a recommendation based on existing conditions and current information. Actual development of future users may necessitate modification of the phasing sequence.

TABLE 10-1

IMPLEMENTATION PHASES
PRIORITY LIST

PHASE	ZONE	YEAR	WATER DEMAND (ACRE-FEET)
1	IA	1994	1530
2	IIIA	1996	220
3	VI	1998	430
4	IB	2000	1935
5	II	2002	579
6	IIIB	2005	2412
7	IC	2010	1595
8	IV	After 2010	445
9	V	After 2010	1215

Implementation phases are delineated on Plate 4 and described in the following sections. Reclaimed water users, facility requirements, and preliminary cost estimates for each phase are summarized in Tables 10-2, 10-3, and 10-4, respectively.

Phase 1

Phase 1 (Zone IA) consists of the following existing reclaimed water users located in the vicinity of the Valencia WRP:

- Magic Mountain Amusement Park
- Windmill Tree Farm

In addition, the Westridge development, a future user ultimately part of Zone IIIA, would be temporarily served by Zone IA until Phase 2 construction is complete. Construction of a temporary pump station by the developers will be required until completion of booster pump station number 3 in Phase 2. The Phase I users have a total annual demand of 1,530 acre-feet per year, a peak monthly demand of approximately 310 acre-feet per month, and a peak hourly demand of 5,820 gallons per minute (gpm).

Total Construction Cost (Including Phase 9 - Stevenson Ranch outside CLWA Boundaries):	**$33,615,000**

085305

07708

Facilities to be constructed in Phase 1 include a 2,000-gpm reuse pump station to be constructed at the Valencia WRP, a 3.1-million-gallon (MG) reservoir, a 2,500-gpm booster pump station, and 26,175 linear feet of distribution pipelines ranging from 16 to 36 inches in diameter. The construction cost of the facilities is estimated to be $5,406,000 (1993 dollars).

Environmental documentation for Phase I was completed in 1991 and consisted of two primary documents:

- CLWA's "Final Program EIR for the Capital Program and Water Plan including Acquisition of Supplemental Water and Proposed Second Plant Site".
- CLWA's "Site Specific Mitigated Negative Declaration for Construction of a Reclaimed Water Distribution System".

Design of Phase I has already begun and is anticipated to be complete in late 1994.

Phase 2

Phase 2 (Zone IIIA) consists of the following reclaimed water users west of Interstate 5 (I-5) near McBean Parkway:

- Stevenson Ranch Phase I slopes
- Valencia Marketplace

The Valencia Marketplace is a future user. The users have a total annual demand of 220 acre-feet per year, a peak monthly demand of approximately 42 acre-feet per month, and a peak hourly demand of 1,232 gpm.

Facilities to be constructed in Phase 2 include a 2,000-gpm expansion to the reuse pump station at the Valencia WRP, a 2.2-MG reservoir, a 1,870-gpm booster pump station, and 22,400 linear feet of distribution pipelines ranging from 12 to 20 inches in diameter. The construction cost of the facilities is estimated to be $3,532,000 (1993 dollars).

Phase 3

Phase 3 (Zone VI) consists of the following reclaimed water users located near McBean Parkway just west of Zone IIIA:

- Stevenson Ranch Phase I park
- Stevenson Ranch Phase II slopes, park and school

Phase II of Stevenson Ranch is a future user. The users have a total annual demand of 430 acre-feet per year, a peak monthly demand of approximately 82 acre-feet per month, and a peak hourly demand of 2,407 gpm.

Facilities to be constructed in Phase 3 include a 0.7-MG reservoir, a 1,200-gpm booster pump station, a 1,870-gpm expansion to booster pump station number 3, and 24,400 linear feet of distribution pipelines ranging from 6 to 12 inches in diameter. The construction cost of the facilities is estimated to be $1,942,000 (1993 dollars).

Phase 4

Phase 4 (Zone IB) consists of the following users located east and west of I-5 and north of Valencia Boulevard to San Francisquito Canyon:

- Valencia interchange at I-5
- Valencia Golf Course
- Magic Mountain Golf Course
- North River development
- City Center development

Magic Mountain Golf Course, North River development, and City Center development are future users. The users have a total annual demand of 1,935 acre-feet per year, a peak monthly demand of approximately 339 acre-feet per month, and a peak hourly demand of 8,407 gpm.

Facilities to be constructed in Phase 4 include a 2,000-gpm expansion to the reuse pump station at the Valencia WRP, a 1,000-gpm expansion to booster pump station number 1, a 1.0-MG reservoir, and 40,250 linear feet of distribution pipelines ranging from 12 to 24 inches in diameter. The construction cost of the facilities is estimated to be $3,579,000 (1993 dollars).

Phase 5

Phase 5 (Zone II) consists of the following reclaimed water users in the Soledad Canyon and Bouquet Canyon area:

- Civic Center
- Saugus High School
- Rio Vista Center
- Panhandle development
- City Civic Center
- City Center development

The Rio Vista Center. Panhandle development. City Civic Center and the City Center development are future users. The users have a total annual demand of 579 acre-feet per year, a peak monthly demand of approximately 111 acre-feet per month, and a peak hourly demand of 3,068 gpm.

Facilities to be constructed in Phase 5 include a 1,500-gpm reuse pump station at the Saugus WRP, a 1.0-MG reservoir, and 25,600 linear feet of distribution pipelines ranging from 8 to 16 inches in diameter. The construction cost of the facilities is estimated to be $2,793,000 (1993 dollars).

Phase 6

Phase 6 (Zone IIIB) consists of the following reclaimed water users located in the Newhall and southern Valencia areas east of I-5:

- Vista Valencia Golf Course
- Henry Mayo Hospital
- College of the Canyons
- College of the Masters
- California Institute of the Arts
- Hart High School
- Placerita Junior High School
- Five elementary schools
- Five parks
- Tree farm
- Cogeneration plant
- McBean Parkway interchange at I-5
- Palmer Tract

The Palmer Tract is the only future user. The users have a total annual demand of 2,412 acre-feet per year, a peak monthly demand of approximately 373 acre-feet per month, and a peak hourly demand of 8,018 gpm.

Facilities to be constructed in Phase 6 include a 4,000-gpm expansion of the reuse pump station at the Valencia WRP, a 2.4-MG reservoir, a 3,500-gpm booster pump station, and 59,075 linear feet of distribution pipelines ranging from 6 to 20 inches in diameter. The construction cost of the facilities is estimated to be $6,043,000 (1993 dollars).

Phase 7

Phase 7 (Zone IC) consists of the following users located near I-5, north of Castaic Junction (Highway 126):

- Castaic Lagoon landscaping
- Honor Rancho Golf Course
- County Sports Complex
- Northlake development
- Commerce Center

The landscaping around Castaic Lagoon is currently the only existing user. The users have a total annual demand of 1,595 acre-feet per year, a peak monthly demand of approximately 347 acre-feet per month, and a peak hourly demand of 7,157 gpm.

Facilities to be constructed in Phase 7 include a 1,500-gpm expansion to the reuse pump station at the Saugus WRP, a 2.5-MG reservoir, a 4,100-gpm booster pump station, and 48,200 linear feet of distribution pipelines ranging from 6 to 20 inches in diameter. The construction cost of the facilities is estimated to be $5,242,000 (1993 dollars).

Phase 8

Phase 8 (Zone IV) consists of the following users located near Highway 14 (Antelope Valley Freeway) from San Fernando Road to Via Princessa:

- Eternal Valley Cemetery
- Valley View Elementary
- Friendly Valley Golf Course
- Park
- First Financial development

The park and First Financial development are both future users. The total annual demand of 445 acre-feet per year, a peak monthly demand of approximately 84 acre-feet per month, and a peak hourly demand of 2,327 gpm.

Facilities to be constructed in Phase 8 include a 0.7-MG reservoir, a 1,250 gpm booster pump station, and 28,000 linear feet of distribution pipelines ranging from 6 to 12 inches in diameter. The construction cost of the facilities is estimated to be $1,917,000 (1993 dollars).

Specific locations for Phase 8 facilities were not determined due to the uncertainty of future developments and the proposed schedule extending beyond the year 2010.

Phase 9 (Outside CLWA Boundaries)

Zone V is a small portion of Stevenson Ranch currently lying outside CLWA's service boundaries. Located west of Zone VI, the users have a total annual demand of 1,215 acre-feet per year, a peak monthly demand of approximately 233 acre-feet per month, and a peak hourly demand of 6,801 gpm.

Facilities to be constructed in Zone V include a 2,000-gpm expansion to the reuse pump station at the Valencia WRP, a 1.9-MG reservoir, a 2,270-gpm booster pump station, and 23,300 linear feet of distribution pipelines ranging from 6 to 20 inches in diameter. The construction cost of the facilities is estimated to be $3,161,000 (1993 dollars).

WATER RIGHTS

A determination of rights to treated wastewater is required prior to long-term project expenditures. Ownership of the rights to wastewater are addressed in three separate state laws or codes:

- Clean Water and Water Bond Law of 1978
- California Department of Fish and Game Code, Section 1600
- Water Code, Section 1210

The Clean Water and Water Bond Law of 1978 established that treated wastewater was the property of the treatment facility that produced it and that the producer could sell or transfer its rights to the treated wastewater. In addition, the rights of the treatment facility allowed the treated wastewater to be used for beneficial purposes regardless of the detriment to downstream users. However, the advice of legal counsel for individual determinations and the development of most equitable and least detrimental projects to all affected parties is recommended.

The California Department of Fish and Game Code Section 1600 requires that "any project which will divert, obstruct or change the natural flow or bed, channel or bank of any river, stream or lake designated by the department in which there is at any time an existing fish or wildlife resource or from which these resources derive benefit" be modified sufficiently "for the protection and continuance of the fish or wildlife resources". On the Santa Clara River, there are users of river water downstream of the Saugus and Valencia WRPs, as well as Essential Habitat Area for an endangered species. Potential impacts to these users and the habitat should be addressed in the environmental documents to be prepared for this proposed reclaimed water project.

Water Code Section 1210 gives the wastewater treatment plant owner exclusive rights to its treated wastewater, but does not relieve him of obligations to any legal user of the discharged wastewater. Thus, if downstream or secondary appropriators of wastewater flow are considered to be legal users, the right of producers to reclaimed water could be limited.

These laws and codes do not directly address differences between "natural water" and "foreign water"; however, previous caselaw appears to clearly establish the right to divert foreign water. In Stevens v. Oakdale Irrigation District (1939) 13 Cal. 2d 343, 352, the court determined that an entity, "after importing water from one river, passing it through [water] works, and discharging it into a natural creek bed in the second water shed, may change the flow of water imported or the volume of water discharged from its works into the second stream, or stop the flow entirely, so long as this is done above the point where the water leaves the works of the district or the boundaries of its land". The exceptions to this decision include instances "where the artificial condition has become inherently permanent and there has been a dedication to the public use, or where the drainage is stopped wantonly to harm a lower party, without other object."

TABLE 10-5

WATER SUPPLY ANALYSIS

YEAR	TOTAL NET M & I DEMAND (1) (AC-FT/YR)	IMPORTED WATER (AC-FT/YR)	WASTEWATER GENERATION (AC-FT/YR)	RECLAIMED WATER (AC-FT/YR)	RATIO OF IMPORTED WATER TO TOTAL M&I DEMAND	RATIO OF RECLAIMED WATER TO WASTEWATER GENERATION
1993	60769	10784	14667	0	17.75%	0.00%

2008	102361	43735	26141	7551	42.73%	28.89%
2009	105367	45909	26851	7551	43.57%	28.12%
2010	108012	44075	27560	9146	40.81%	33.19%

(1) See Table 3-1 notes for assumptions

Groundwater extracted from and used in the Santa Clarita Valley and then discharged to the Santa Clara River as wastewater effluent may be considered a "natural water" in the river under the California Department of Fish and Game Code Section 1600; however, State Water Project water imported into and used in the Santa Clarita Valley and then discharged to the Santa Clara River as wastewater effluent is clearly a "foreign water". Furthermore, while it could be argued that the existing discharges have a permanent, public use (i.e., habitat), the increased flows to the wastewater treatment plants can be diverted for reclamation.

It should be noted that approximately 41 percent of the total projected water demand in the year 2010 is expected to be derived from imported water whereas reclaimed water only represents approximately 33 percent of projected wastewater generation (38 percent including Zone V). Table 10-5 presents a water supply analysis for the CLWA service area through the year 2010. The table projects how available supplies are expected to meet the municipal and industrial demand. Included in the table is a ratio of annual reclaimed water use to annual imported water use. The maximum reclaimed water use occurs in the year 2010 and is equivalent to approximately one fifth of the total imported water projected for the year 2010.

PERMIT REQUIREMENTS

A number of permits will be required for each phase of the recommended plan. Because the permitting process can be lengthy, permitting requirements may affect the implementation schedule of the reclaimed water system. A summary of the regulatory requirements is shown in Table 10-6.

Federal

It is anticipated that only one Federal permit will be required for the recommended reclaimed water system. A Nationwide 404 Permit from the United States Army Corp of Engineers (Corp) is required for activities impacting the waters of the United States. The proposed river crossings would be accomplished by bridge suspension. Because some construction activities may occur within the riverbed, it is recommended that the Corp be notified in writing of the proposed activities.

State

The following state agencies may require permits and/or approvals for the reclaimed water system:

- California Department of Fish & Game
- California Department of Transportation
- California Department of Health Services
- Regional Water Quality Control Board
- State Water Resources Control Board

TABLE 10-6

REGULATORY REQUIREMENTS

	AGENCY	TYPE OF APPROVAL	REQUIREMENTS	TYPICAL REVIEW PERIOD	COMMENTS
I. FEDERAL PERMITS	United States Army Corps of Engineers (ACE)	Nationwide 404 Permit	Probably not required. Notify ACE of activities	30-60 Days	Notify ACE of activities
II. STATE PERMITS	California Department of Fish and Game	1601 Permit for impact on or activity in streams	Construction plans with application	30 Days	Avoid nesting season April through September
	California Department of Transportation	Encroachment Permit	Six sets of construction plans with application	4-8 Weeks	Inspection required during construction
	California Department of Health Services	Cross connection control	Construction plans with specifications	Not Applicable	Project must conform to Title 22, DHS and AWWA Guidelines
	Regional Water Quality Control Board	NPDES Construction Activity Permit	Application (NOI) before construction starts	60 Days	Required for project area greater than 5 acres
	Regional Water Quality Control Board	Reclamation Permit	Application, Letter, plans, user maps, quantities	6-9 Months	Will take lead CSDLAC
	Regional Water Quality Control Board	Engineering report requirements	Application, Letter, plans, user maps, quantities	6-9 Months	Will take lead CSDLAC
	State Water Resources Control Board	Petition for change in place and purpose of use	Petition	Varies	CSDLAC will take lead
III. LOCAL PERMITS	City of Santa Clarita	Encroachment Permit	Construction plans with permit application	60 Days	Inspection required following construction
	Los Angeles County Department of Public Works	Excavation Permit	Construction plans with permit application	3-6 Weeks	Inspection required throughout construction
	Los Angeles County Flood Control District	Encroachment Permit	Six sets of construction plans with application	60 Days	Inspection required following construction
	Los Angeles County Department of Health Services	Distribution system design & construction approval	Construction plans and specifications	Depends on project	Inspection required following construction, prior to operation
	Los Angeles County Department of Health Services	Onsite (cross connection control) (user) facilities approval	As-builts of onsite facilities	Not Applicable	Onsite inspection following construction

The 1601 Agreement from the California Department of Fish & Game (DFG) is required for all crossings or activities which may impact a streambed or natural drainage way. This requirement includes construction of pipelines on bridges if construction activity occurs within the streambed. The proposed system has four pipeline crossings of the Santa Clara River that will be supported on bridges: Old Road Bridge, McBean Parkway Bridge, Bouquet Canyon Road Bridge and Southern Pacific's abandoned Railroad Bridge. In addition, there are several crossings of minor streams that may require 1601 Agreements. An Endangered Species Permit may be required by DFG for portions of or for the total reclaimed water system.

An encroachment permit from the California Department of Transportation will be required for any work done within the state right-of-way. This includes installation of a pipeline in a roadway crossing under a highway, support of a pipeline on a bridge crossing over a highway, and activities that impact on-ramp and off-ramp traffic. The proposed system has two pipeline crossings over Interstate 5: McBean Parkway and Valencia Boulevard. Inspection will be required.

The California Department of Health Services (DHS) will be involved during implementation of the reclaimed water system. The DHS is concerned with cross connections, separation of pipelines, and any activity that may result in contamination of drinking water. The DHS will review plans and specifications prior to construction.

The RWQCB regulates the source and the end use of reclaimed water. Its main involvement in the reclaimed water system will be through the County Sanitation Districts of Los Angeles County (CSDLAC) to modify the reclamation permit to include the specific reclaimed water users and to review the Engineering Report describing treatment and distribution facilities and users. CLWA's responsibility will be to assist CSDLAC with preparation of necessary information. In addition, CLWA will need to obtain National Pollutants Discharge Elimination System (NPDES) Construction Activity Permits. These permits are required for stormwater runoff from construction projects impacting an area of 5 acres or more.

Water rights and funding alternatives will require involvement from the State Water Resources Control Board (SWRCB). Approval of a Petition for Change of Place and Purpose of Use is required for any change in discharge location or quantity of wastewater. In addition, if CSDLAC pursues the rights to the effluent, review and approval is the responsibility of SWRCB. In either case, CSDLAC would be the lead agency, requiring assistance from CLWA. If CLWA chooses a low interest loan as a funding alternative, applications for the Water Reclamation Loan Program and State Revolving Fund are through the SWRCB.

Local

Concerned with drinking water contamination (cross connection control), the Los Angeles County Department of Health Services requires plan review and inspection of the distribution system and onsite user facilities. The County Department of Health Services coordinates with RWQCB and State DHS.

Encroachment permits are required for all construction work done within local right-of-way. These include the City of Santa Clarita, the Los Angeles County Department of Public Works (Excavation Permit), and the Los Angeles County Flood Control District.

CALIFORNIA ENVIRONMENTAL QUALITY ACT

In addition to the permits and approvals described above, compliance with the California Environmental Quality Act (CEQA) will be required. Preparation of environmental documents for the master plan as well as preparation of a negative declaration for each implementation phase will be necessary. CLWA's "Final Program EIR for the Capital Program and Water Plan", including "Acquisition of Supplemental Water and Proposed Second Plant Site", included use of 1,700 acre-feet of reclaimed water. CLWA's "Site Specific Mitigated Negative Declaration for Construction of a Reclaimed Water Distribution System" includes the Phase I facilities.

OTHER INSTITUTIONAL ISSUES

Before providing reclaimed water service, it will be necessary to secure agreements between the following entities:

- CSDLAC and CLWA
- CLWA and Purveyors
- Purveyors and Users

A contract between CSDLAC and CLWA is required for sale of reclaimed water to CLWA and construction and operation of facilities on CSDLAC property. Contracts between CLWA and local water purveyors will establish the basis for operation of the system and sale of reclaimed water. The agreement between purveyors and users (customer service agreement) will establish the requirements for use of reclaimed water and will specify that the users understand the regulations controlling use of reclaimed water.

IMPLEMENTATION SCHEDULE

Table 10-1 shows the recommended phasing of each service zone. Because the availability of reclaimed water is dependent upon the production of the Valencia and Saugus WRPs, implementation of the phases should be based on the projected flows from the WRPs. Based on the projected flows from the WRPs, it is proposed that Phase 1 be implemented in 1994 and phases 2 through 5 be implemented every 2 years thereafter to the year 2002. Phases 6 and 7 are proposed for implementation in

the years 2005 and 2010, respectively. Zone 8 is proposed for implementation following the year 2010; the exact implementation date will depend on the schedule of proposed future developments. If Zone V is annexed into the CLWA service area, Phase 9 most likely will be implemented sometime after 2010. The recommended implementation schedule and the resulting annual Santa Clara River discharge after implementation of each phase is shown in Table 10-7. The projected average daily production of the WRPs and the projected average daily discharge to the river are presented on Figure 10-1.

The primary activities involved in the construction of each phase and the anticipated time to complete each activity are as follows:

Activity	Duration
Environmental documentation	6 months
Funding	6 months
Design	6 months
Permitting/Institutional	18 months
Bidding and contract award	2 months
Construction and testing	10 months

Overlapping of the activities may be necessary. An implementation schedule is presented on Plate 5.

* Assumed 2010 supply since year of implementation for Zone IV is unknown.

CHAPTER 11

FINANCING PLAN

To implement construction of the reclaimed water system, sufficient capital and operating funds must be secured by the Castaic Lake Water Agency (CLWA). This chapter presents a financing plan for the proposed reclaimed water system. Discussions on financing alternatives, water rate policy, economic analysis and connection fees are included.

FINANCING ALTERNATIVES

To finance the construction cost of the proposed facilities, CLWA can obtain sufficient capital through the following funding sources:

- Capital Improvement Program Funds
- Water Reclamation Loan Program
- State Revolving Fund
- Small Reclamation Projects Act of 1956

Capital Improvement Program Funds

CLWA maintains Capital Improvement Program (CIP) funds, the source of which are standby charges and water rates paid by existing customers, property taxes paid by existing landowners within CLWA's boundary, and connection fees paid by new development. The purpose of the CIP funds according to CLWA's Data Document for Fiscal Year 93/94 is "to fund acquisition, construction, enlargement and/or provision of water importation, transportation, treatment, storage, and distribution facilities, as well as other works, property, and improvements necessary to obtain and provide additional supplies of water to those retail distributors who serve water to the lands on which new developments and new construction will be located." Development of reclaimed water is included as one of CLWA's CIP projects and can be funded through the CIP.

Water Reclamation Loan Program

The development of cost-effective water reclamation projects for the augmentation of water supplies constitutes the main purpose of the Water Reclamation Loan Program (WRLP). The WRLP is administered by the SWRCB's Office of Water Recycling and provides $30 million to local public agencies under the Clean Water and Water Reclamation Bond Law of 1988. These funds are available to assist in the design and construction costs of water reclamation projects. Although a maximum loan amount per project is not specified in the Bond Loan, SWRCB policy limits each project to $5 million. Loans covering 100 percent of eligible costs may be provided for a maximum period of 20 years at an interest rate of one-half the rate paid by the State on the most recent sale of state general obligation bonds. The present rate is 4 percent. A water reclamation project is eligible for the WRLP under the 1988 Bond Law if it is cost-effective compared to the cost of new freshwater supply alternatives and if no federal assistance is available at the time of need. Available funds will generally be committed to those projects with completed facilities planning which have met all loan program requirements and are ready to proceed. General requirements include a completed facilities plan with a project report, a complete environmental document, and a draft revenue program. In addition, all projects must comply with the California Environmental Quality Act (CEQA) prior to loan authorization. According to SWRCB staff, funds for projects in the near future are very limited.

State Revolving Fund

Created by the Federal Clean Water Act and administered by the State Water Resources Control Board (SWRCB), the State Revolving Fund (SRF) offers low cost loans capitalized in part by federal funds. The primary objective of the SRF is to assist in the construction of publicly-owned treatment works (POTWs) for the protection and promotion of public health, safety, and welfare. The loans are distributed based on a priority system that ranks projects in classes from "A" to "F". Reclamation projects are ranked in class E and receive lower priority than projects ranked A through D. A loan term of 20 years with the first loan repayment due one year after project completion is set for projects costing under $25 million, and an interest rate of one-half the rate of the most recent government obligation bond sales is applied. The amount of funding available for reclamation projects is generally more readily available for the SRF than the WRLP. In general, projects must meet similar requirements to be eligible for either SRF or WRLP assistance; however, because the SRF includes federal funds, compliance with the National Environmental Protection Act (NEPA) and other federal regulations is required.

Small Reclamation Projects Act of 1956

Funds are provided under the U.S. Bureau of Reclamation's Small Reclamation Projects Act of 1956, which has the following objective:

> "to bring about improvement in resource management of infrastructure, to achieve more effective and efficient use of water and related resources, and to achieve broader and more contemporary public value benefits and national resource objectives that might not otherwise be implemented in the absence of those Federal assistance loan programs".

Eligibility is based on specific elements that are addressed by the proposed project. Specifically, the project must include commercial irrigation and must address at least two of the five "Natural Resources and Water Policy Objectives". The CLWA reclaimed water project would most likely address objective 2, Water Conservation to Meet Changing Water Use Demands, and objective 3, Maintaining and Enhancing the Environment. Phases of the reclaimed water project that include irrigation of tree farms would meet the requirement for including commercial irrigation; however funding of these phases would most likely be low priority because commercial irrigation is such a small percentage of these phases. The current interest rate is 7.5 percent.

Recommended Alternative

Funding through the CIP funds remains a viable option for CLWA. However, due to the low interest rates of the WRLP and the SRF programs, CLWA should consider maintaining its accumulated reserves for other purposes and finance the reclaimed water project through the WRLP or SRF. According to SWRCB staff, WRLP funds are very limited in the near future; SRF funds are generally more readily available.

It should be noted that the SWRCB closely reviews project planning and construction documents for both the WRLP and SRF loans and must conclude that the selected alternative is the most cost-effective alternative. The loans are not retroactive; therefore, SWRCB must approve the project prior to construction. It is recommended that coordination with SWRCB occur immediately following completion of the planning documents.

ECONOMIC ANALYSIS

An economic analysis was performed for the proposed reclaimed water system. Unit cost (annual cost per acre-foot of reclaimed water demand) for each phase is listed in Table 11-1. In order to calculate the unit cost, the annualized capital cost for each phase was added to the estimated annual water purchase cost and the estimated annual operations and maintenance (O&M) cost. The total annual cost (annualized capital, water purchase, and O&M) was then divided by the estimated reclaimed water demand for each phase to obtain the unit cost.

Annualized capital costs were calculated based on a 20-year period at a 4 percent interest rate. Annual water purchase costs were estimated by multiplying the reclaimed water demand for each phase by the current cost of reclaimed water as estimated by County Sanitation Districts of Los Angeles County ($60 per acre-foot). Annual O&M costs were estimated by combining estimated pumping costs, parts cost, and labor costs. Pumping costs were estimated based on 85 percent pump efficiencies, 90 percent motor efficiencies, and an electricity cost of $0.10 per kilowatt-hour. Parts costs were estimated to be 1 percent of construction costs of pump stations and 0.1 percent of construction cost of reservoirs and pipelines. Labor costs were estimated based on 3 man-days per month per phase at $25 per hour.

As shown in Table 11-1, the total average annual unit cost (1993 dollars), including annualized capital, after implementation of the completed reclaimed water system is $391 per acre-foot. This cost assumes CLWA finances construction of the project through the WRLP or the SRF. Because CLWA can utilize CIP funds to repay WRLP or SRF debt service, it will not be necessary to recover capital costs. Therefore, the average unit cost of reclaimed water is $146 per acre-foot. The unit cost of each phase based on O&M costs and water purchase costs are included in Table 11-1.

WATER RATE POLICY

To encourage its use, reclaimed water should be available at a lower rate to users than potable water. Because reclaimed water is a reliable source of supply, this cost differential should provide potential customers with the necessary encouragement to use reclaimed water. The wholesale rate of potable water is currently $145 per acre-foot. The retail rate of potable water in the Santa Clarita Valley is on the range of $100 to $150 per acre-foot more than the wholesale rate.

The principal wholesale rate strategies for reclaimed water are discussed below.

Rates Based on Costs of Service

The wholesale reclaimed water rate could be set at a level to recover costs of furnishing the reclaimed water. The estimated cost of the reclaimed water system in 1993 dollars is approximately $391 per acre-foot which is significantly greater than the $145 per acre-foot wholesale rate for potable water. This rate includes annualized capital cost, water purchase cost, and O&M cost.

Regardless of the program utilized to finance the reclaimed water system, the basic source of funds is the connection fees, standby charges, property taxes, and water rates currently collected by CLWA. Therefore, it is not necessary to include annualized capital in the cost of service since the capital costs do not need to be recovered. The estimated cost for the reclaimed water system excluding annualized capital costs is approximately $146 per acre-foot (1993 dollars) which is approximately the same as the current wholesale rate for potable water.

Rates Based on Percentage of Potable Water Rate

Although the wholesale reclaimed water rate should reflect the actual cost of providing service, it may be preferable for CLWA to base its reclaimed water rate on a percentage of the potable water rate. This is desirable when a straightforward method of calculation is preferred. Often, this method is necessary because the rate based upon costs of service exceeds the potable water rate. Based on the need to provide an incentive to utilize reclaimed water, a reclaimed water rate of 70 to 90 percent of the potable water rate is typical.

Rates by User Class

A method used by some water agencies for setting reclaimed water rates is to establish different rates for various user categories. For example, the Irvine Ranch Water District charges a rate for commercial/landscape users (including homeowner associations) that is approximately nine percent greater than the rate charged for

(1) Assumes 20 year period at 4% interest rate.

(2) Cost to purchase reclaimed water from County Sanitation Districts of Los Angeles County. Current cost estimated to be $60/acre-feet

(3) Assumes 85% pump efficiency, 90% motor efficiency, and electricity cost of $0.10 per KW-hr. Includes operation costs of booster and reuse pumps.

(4) Assumes annual parts costs to be 1% of construction costs of pumping stations, plus 0.1% of construction costs of storage reservoirs and pipelines.

(5) Assumes 3 man-days per month at $25 per hour.

085322

the larger irrigation/agricultural users. Because the cost of furnishing reclaimed water would not differ substantially between types of customers, it seems appropriate for users of CLWA's reclaimed water system to be initially charged at the same rate. However, a rate surcharge may be appropriate for users of high pressure water since pumping costs are higher.

Recommended Rate Policy

It is recommended that CLWA utilize a wholesale reclaimed water rate equivalent to the potable water rate of $145 per acre-foot and that the water purveyors utilize a retail reclaimed water rate equivalent to the potable water rate. The estimated cost of service for the reclaimed water system is $146 per acre-foot (1993 dollars) as shown in Table 11-1. Utilizing the potable rate for reclaimed water allows CLWA to recover the cost of reclaimed water service while avoiding potential problems that investor-owned water companies may face when presenting a reclaimed water rate case to the Public Utilities Commission and while assuring that the water purveyors experience no loss in revenue.

In order to provide an incentive to reclaimed water users, it is recommended the CLWA issue a monthly rebate directly to the reclaimed water users. The recommended initial rebate is $60 per acre-foot. Based on existing retail potable water rates, the rebate would result in a cost incentive for reclaimed water users of 20 to 25 percent over potable water rates.

CONNECTION FEE POLICY

Connection fees for the reclaimed water system can be approached in two ways:

- A connection fee applicable to reclaimed water can be imposed.
- A standard connection fee applicable to both potable and reclaimed water can be imposed.

The first method would require that separate connection fees be calculated for potable water and reclaimed water each year. This method would impose a connection fee based on the source of the water. In effect, CLWA would have two connection fees: one for potable water projects and one for reclaimed water projects. Connection fees would be calculated based on the respective CIP. Connection fees paid by developers seeking to use reclaimed water exclusively would be allocated specifically to the reclaimed water CIP.

The second method would be a continuation of the current method. This method considers any source of water as an additional supply contributing to the total available water supply in the Valley. "Total available water supply" is the key phrase, not "source of water." Connection fees paid by developers seeking to use potable water or reclaimed water would all be allocated to the CIP.

Recommended Connection Fee Policy

Even though it is not equally accessible throughout the Agency, reclaimed water is considered a water resource for the entire service area because it allows CLWA's other water resources to be available in areas where reclaimed water is not available. However, the reclaimed water system does not benefit each of CLWA's water service areas. Accordingly, it is recommended that a uniform connection fee be maintained for both potable and reclaimed water service.

Chapter 3. Reclamation Criteria

Article 1. Definitions

§ 60301. Definitions.

(a) Reclaimed Water. Reclaimed water means water which, as a result of treatment of domestic wastewater, is suitable for a direct beneficial use or a controlled use that would not otherwise occur.

(b) Reclamation Plant. Reclamation plant means an arrangement of devices, structures, equipment, processes and controls which produce a reclaimed water suitable for the intended reuse.

(c) Regulatory Agency. Regulatory agency means the California Regional Water Quality Control Board in whose jurisdictions the reclamation plan is located.

(d) Direct Beneficial Use. Direct beneficial use means the use of reclaimed water which has been transported from the point of production to the point of use without an intervening discharge to waters of the State.

(e) Food Crops. Food crops mean any crops intended for human consumption.

(f) Spray Irrigation. Spray irrigation means application of reclaimed water to crops by spraying it from orifices in piping.

(g) Surface Irrigation. Spray irrigation means application of reclaimed water by means other than spraying such that contact between the edible portion of any food crop and reclaimed water is prevented.

(h) Restricted Recreational Impoundment. A restricted recreational impoundment is a body of reclaimed water in which recreation is limited to fishing, boating, and other non–body–contact water recreational activities.

(i) Nonrestricted Recreational Impoundment. A nonrestricted recreational impoundment is a body of reclaimed water in which no limitations are imposed on body–contact water sport activities.

07734

085331

(j) Landscape Impoundment. A landscape impoundment is a body of reclaimed water which is used for aesthetic enjoyment or which otherwise serves a function not intended to include public contact.

(k) Approved Laboratory Methods. Approved laboratory methods are those specified in the latest edition of "Standard Methods for the Examination of Water and Wastewater," prepared and published jointly by the the American Public Health Association, the American Water Works Association, and the Water Pollution Control Federation and which are conducted in laboratories approved by the State Department of Health.

(l) Unit Process. Unit process means an individual stage in the wastewater treatment sequence which performs a major single treatment operation.

(m) Primary Effluent. Primary effluent is the effluent from a wastewater treatment process which provides removal of sewage solids so that it contains not more than 0.5 milliliter per liter per hour of settleable solids as determined by an approved laboratory method.

(n) Oxidized Wastewater. Oxidized wastewater means wastewater in which the organic matter has been stabilized, is nonputrescible, and contains dissolved oxygen.

(o) Biological Treatment. Biological treatment means methods of wastewater treatment in which bacterial or biochemical action is intensified as a means of producing an oxidized wastewater.

(p) Secondary Sedimentation. Secondary sedimentation means the removal by gravity of settleable solids remaining in the effluent after the biological treatment process.

(q) Coagulated Wastewater. Coagulated wastewater means oxidized wastewater in which colloidal and finely divided suspended matter have been destabilized and agglomerated by the addition of suitable floc-forming chemicals or by an equally effective method.

(r) Filtered Wastewater. Filtered wastewater means an oxidized, coagulated, clarified wastewater which has been passed through natural undisturbed soils or filter media, such as sand or diatomaceous earth, so that the turbidity as determined by an approved laboratory method does not exceed an average operating turbidity of 2 turbidity units and does not exceed 5 turbidity units more than 5 percent of the time during any 24-hour period.

(s) Disinfected Wastewater. Disinfected wastewater means wastewater in which the pathogenic organisms have been destroyed by chemical, physical or biological means.

(t) Multiple Units. Multiple units means two or more units of a treatment process which operate in parallel and serve the same function.

(u) Standby Unit Process. A standby unit process is an alternate unit process or an equivalent alternative process which is maintained in operable condition and which is capable of providing comparable treatment of the entire design flow of the unit for which it is a substitute.

(v) Power Source. Power source means a source of supplying energy to operate unit processes.

(w) Standby Power Source. Standby power source means an automatically actuated self-starting alternate energy source maintained in immediately operable condition and of sufficient capacity to provide necessary service during failure of the normal power supply.

(x) Standby Replacement Equipment. Standby replacement equipment means reserve parts and equipment to replace broken-down or worn-out units which can be placed in operation within a 24-hour period.

(y) Standby Chlorinator. A standby chlorinator means a duplicate chlorinator for reclamation plants having one chlorinator and a duplicate of the largest unit for plants having multiple chlorinator units.

(z) Multiple Point Chlorination. Multiple point chlorination means that chlorine will be applied simultaneously at the reclamation plant and at subsequent chlorination stations located at the use area and/or some intermediate point. It does not include chlorine application for odor control purposes.

(aa) Alarm. Alarm means an instrument or device which continuously monitors a specific function of a treatment process and automatically gives warning of an unsafe or undesirable condition by means of visual and audible signals.

(bb) Person. Person also includes any private entity, city, county, district, the State or any department or agency thereof.

NOTE: Authority cited: Section 208, Health and Safety Code and Section 13521, Water Code. Reference: Section 13521, Water Code.

HISTORY

1. New Chapter 4 (§§ 60301–60357, not consecutive) filed 4–2–75; effective thirtieth day thereafter (Register 75, No. 14).
2. Renumbering of Chapter 4 (Sections 60301–60357, not consecutive) to Chapter 3 (Sections 60301–60357, not consecutive), filed 10–14–77; effective thirtieth day thereafter (Register 77, No. 42).

Article 2. Irrigation of Food Crops

§ 60303. Spray Irrigation.

Reclaimed water used for the spray irrigation of food crops shall be at all times an adequately disinfected, oxidized, coagulated, clarified, filtered wastewater. The wastewater shall be considered adequately disinfected if at some location in the treatment process the median number of coliform organisims does not exceed 2.2 per 100 milliliters and the number of coliform organisms does not exceed 23 per 100 milliliters in more than one sample within an 30-day period. The median value shall be determined from the bacteriological results of the last 7 days for which analyses have been completed.

§ 60305. Surface Irrigation.

(a) Reclaimed water used for surface irrigation of food crops shall be at all times an adequately disinfected, oxidized wastewater. The wastewater shall be considered adequately disinfected if at some location in the treatment process the median number of coliform organisms does not exceed 2.2 per 100 milliliters, as determined from the bacteriological results of the last 7 days for which analyses have been completed.

(b) Orchards and vineyards may be surface irrigated with reclaimed water that has the quality at least equivalent to that of primary effluent provided that no fruit is harvested that has come in contact with the irrigating water or the ground.

§ 60307. Exceptions.

Exceptions to the quality requirements for reclaimed water used for irrigation of food crops may be considered by the State Department of Health on an individual case basis where the reclaimed water is to be used to irrigate a food crop which must undergo extensive commercial, physical or chemical processing sufficient to destroy pathogenic agents before it is suitable for human consumption.

Article 3. Irrigation of Fodder, Fiber, and Seed Crops

§ 60309. Fodder, Fiber, and Seed Crops.

Reclaimed water used for the surface or spray irrigation of fodder, fiber, and seed crops shall have a level of quality no less than that of primary effluent.

§ 60311. Pasture for Milking Animals.

Reclaimed water used for the irrigation of pasture to which milking cows or goats have access shall be at all times an adequately disinfected, oxidized wastewater. The wastewater shall be considered adequately disinfected if at some location in the treatment process the median number of coliform organisms does not exceed 23 per 100 milliliters, as deter-

07735

085332

mined from the bacteriological results of he last 7 days for which analyses have been completed.

Article 4. Landscape Irrigation

§ 60313. Landscape Irrigation.

(a) Reclaimed water used for the irrigation of golf courses, cemeteries, freeway landscapes, and landscapes in other areas where the public has similar access or exposure shall be at all times an adequately disinfected, oxidized wastewater. The wastewater shall be considered adequately disinfected if the median number of coliform organisms in the effluent does not exceed 23 per 100 milliliters, as determined from the bacteriological results of the last 7 days for which analyses have been completed, and the number of coliform organisms does not exceed 240 per 100 milliliters in any two consecutive samples.

(b) Reclaimed water used for the irrigation of parks, playgrounds, schoolyards, and other areas where the public has similar access or exposure shall be at all times an adequately disinfected, oxidized, coagulated, clarified, filtered wastewater or a wastewater treated by a sequence of unit processes that will assure an equivalent degree of treatment and reliability. The wastewater shall be considered adequately disinfected if the median number of coliform organisms in the effluent does not exceed 2.2 per 100 milliliters, as determined from the bacteriological results of the last 7 days for which analyses have been completed, and the number of coliform organisms does not exceed 23 per 100 milliliters in any sample.

NOTE: Authority cited: Section 208, Health and Safety Code and Section 13521, Water Code. Reference: Section 13520, Water Code.

HISTORY

1. Amendment filed 9-22-78; effective thirtieth day thereafter (Register 78, No. 38).

Article 5. Recreational Impoundments

§ 60315. Nonrestricted Recreational Impoundment.

Reclaimed water used as a source of supply in a nonrestricted recreational impoundment shall be at all times an adequately disinfected, oxidized, coagulated, clarified, filtered wastewater. The wastewater shall be considered adequately disinfected if at some location in the treatment process the median number of coliform organisms does not exceed 2.2 per 100 milliliters and the number of coliform organisms does not exceed 23 per 100 milliliters in more than one sample within any 30-day period. The median value shall be determined from the bacteriological results of the last 7 days for which analyses have been completed.

§ 60317. Restricted Recreational Impoundment.

Reclaimed water used as a source of supply in a restricted recreational impoundment shall be at all times an adequately disinfected, oxidized wastewater. The wastewater shall be considered adequately disinfected if at some location in the treatment process the median number of coliform organisms does not exceed 2.2 per 100 milliliters, as determined from the bacteriological results of the last 7 days for which analyses have been completed.

§ 60319. Landscape Impoundment.

Reclaimed water used as a source of supply in a landscape impoundment shall be at all times an adequately disinfected, oxidized wastewater. The wastewater shall be considered adequately disinfected if at some location in the treatment process the median number of coliform organisms does not exceed 23 per100 milliliters, as determined from the bacteriological results of the last 7 days for which analyses have been completed.

Article 5.1. Groundwater Recharge

§ 60320. Groundwater Recharge.

(a) Reclaimed water used for groundwater recharge of domestic water supply aquifers by surface spreading shall be at all times of a quality that fully protects public health. The State Department of Health Services' recommendations to the Regional Water Quality Control Boards for proposed groundwater recharge projects and for expansion of existing projects will be made on an individual case basis where the use of reclaimed water involves a potential risk to public health.

(b) The State Department of Health Services' recommendations will be based on all relevant aspects of each project, including the following factors: treatment provided; effluent quality and quantity; spreading area operations; soil characteristics; hydrogeology; residence time; and distance to withdrawal.

(c) The State Department of Health Services will hold a public hearing prior to making the final determination regarding the public health aspects of each groundwater recharge project. Final recommendations will be submitted to the Regional Water Quality Control Board in an expeditious manner.

NOTE: Authority cited: Section 208, Health and Safety Code; and Section 13521, Water Code. Reference: Sections 13520 and 13521, Water Code.

HISTORY

1. New Article 5.1 (Section 60320) filed 9-22-78; effective thirtieth day thereafter (Register 78, No. 38).
2. Editorial correction of NOTE filed 12-3-84 (Register 84, No. 49).

Article 5.5. Other Methods of Treatment

§ 60320.5. Other Methods of Treatment.

Methods of treatment other than those included in this chapter and their reliability features may be accepted if the applicant demonstrates to the satisfaction of the State Department of Health that the methods of treatment and reliability features will assure an equal degree of treatment and reliability.

NOTE: Authority cited: Section 208, Health and Safety Code; and Section 13521, Water Code. Reference: Section 13520, Water Code.

HISTORY

1. Renumbering of Article 11 (Section 60357) to Article 5.5 (Section 60320.5) filed 9-22-78; effective thirtieth day thereafter (Register 78, No. 38).

Article 6. Sampling and Analysis

§ 60321. Sampling and Analysis.

(a) Samples for settleable solids and coliform bacteria, where required, shall be collected at least daily and at a time when wastewater characteristics are most demanding on the treatment facilities and disinfection procedures. Turbidity analysis, where required, shall be performed by a continuous recording turbidimeter.

(b) For uses requiring a level of quality no greater than that of primary effluent, samples shall be analyzed by an approved laboratory method of settleable solids.

(c) For uses requiring an adequately disinfected, oxidized wastewater, samples shall be analyzed by an approved laboratory method for coliform bacteria content.

(d) For uses requiring an adequately disinfected, oxidized, coagulated, clarified, filtered wastewater, samples shall be analyzed by approved laboratory methods for turbidity and coliform bacteria content.

Article 7. Engineering Report and Operational Requirements

§ 60323. Engineering Report.

(a) No person shall produce or supply reclaimed water for direct reuse from a proposed water reclamation plant unless he files an engineering report.

(b) The report shall be prepared by a properly qualified engineer registered in California and experienced in the field of wastewater treatment, and shall contain a description of the design of the proposed reclamation system. The report shall clearly indicate the means for compliance with these regulations and any other features specified by the regulatory agency.

(c) The report shall contain a contingency plan which will assure that no untreated or inadequately–treated wastewater will be delivered to the use area.

§ 60325. Personnel.

(a) Each reclamation plant shall be provided with a sufficient number of qualified personnel to operate the facility effectively so as to achieve the required level of treatment at all times.

(b) Qualified personnel shall be those meeting requirements established pursuant to Chapter 9 (commencing with Section 13625) of the Water Code.

NOTE: Authority cited: Section 208, Health and Safety Code; and Section 13521, Water Code. Reference: Sections 13520 and 13521, Water Code.

HISTORY

1. New NOTE filed 12–3–84 (Register 84, No. 49).

§ 60327. Maintenance.

A preventive maintenance program shall be provided at each reclamation plant to ensure that all equipment is kept in a reliable operating condition.

NOTE: Authority cited: Section 208, Health and Safety Code; and Section 13521, Water Code. Reference: Sections 13520 and 13521, Water Code.

HISTORY

1. New NOTE filed 12–3–84 (Register 84, No. 49).

§ 60329. Operating Records and Reports.

(a) Operating records shall be maintained at the reclamation plant or a central depository within the operating agency. These shall include: all analyses specified in the reclamation criteria; records of operational problems, plant and equipment breakdowns, and diversions to emergency storage or disposal; all corrective or preventive action taken.

(b) Process or equipment failures triggering an alarm shall be recorded and maintained as a separate record file. The recorded information shall include the time and cause of failure and corrective action taken.

(c) A monthly summary of operating records as specified under (a) of this section shall be filed monthly with the regulatory agency.

(d) Any discharge of untreated or partially treated wastewater to the use area, and the cessation of same, shall be reported immediately by telephone to the regulatory agency, the State Department of Health, and the local health officer.

NOTE: Authority cited: Section 208, Health and Safety Code; and Section 13521, Water Code. Reference: Sections 13520 and 13521, Water Code.

HISTORY

1. New NOTE filed 12–3–84 (Register 84, No. 49).

§ 60331. Bypass.

There shall be no bypassing of untreated or partially treated wastewater from the reclamation plant or any intermediate unit processes to the point of use.

NOTE: Authority cited: Section 208, Health and Safety Code; and Section 13521, Water Code. Reference: Sections 13520 and 13521, Water Code.

HISTORY

1. New NOTE filed 12–3–84 (Register 84, No. 49).

Article 8. General Requirements of Design

§ 60333. Flexibility of Design.

The design of process piping, equipment arrangement, and unit structures in the reclamation plant must allow for efficiency and convenience in operation and maintenance and provide flexibility of operation to permit the highest possible degree of treatment to be obtained under varying circumstances.

§ 60335. Alarms.

(a) Alarm devices required for various unit processes as specified in other sections of these regulations shall be installed to provide warning of:

(1) Loss of power from the normal power supply.

(2) Failure of a biological treatment process.

(3) Failure of a disinfection process.

(4) Failure of a coagulation process.

(5) Failure of a filtration process.

(6) Any other specific process failure for which warning is required by the regulatory agency.

(b) All required alarm devices shall be independent of the normal power supply of the reclamation plant.

(c) The person to be warned shall be the plant operator, superintendent, or any other responsible person designated by the management of the reclamation plant and capable of taking prompt corrective action.

(d) Individual alarm devices may be connected to a master alarm to sound at a location where it can be conveniently observed by the attendant. In case the reclamation plant is not attended full time, the alarm(s) shall be connected to sound at a police station, fire station or other full–time service unit with which arrangements have been made to alert the person in charge at times that the reclamation plant is unattended.

§ 60337. Power Supply.

The power supply shall be provided with one of the following reliability features:

(a) Alarm and standby power source.

(b) Alarm and automatically actuated short–term retention or disposal provisions as specified in Section 60341.

(c) Automatically actuated long–term storage or disposal provisions as specified in Section 60341.

Article 9. Alternative Reliability Requirements for Uses Permitting Primary Effluent

§ 60339. Primary Treatment.

Reclamation plants producing reclaimed water exclusively for uses for which primary effluent is permitted shall be provided with one of the following reliability features:

(a) Multiple primary treatment units capable of producing primary effluent with one unit not in operation.

(b) Long–term storage or disposal provisions as specified in Section 60341.

Article 10. Alternative Reliability Requirements for Uses Requiring Oxidized, Disinfected Wastewater or Oxidized, Coagulated, Clarified, Filtered, Disinfected Wastewater

§ 60341. Emergency Storage or Disposal.

(a) Where short–term retention or disposal provisions are used as a reliability feature, these shall consist of facilities reserved for the purpose

07737

085334

of storing or disposing of untreated or partially treated wastewater for at least a 24-hour period. The facilities shall include all the necessary diversion devices, provisions for odor control, conduits, and pumping and pump back equipment. All of the equipment other than the pump back equipment shall be either independent of the normal power supply or provided with a standby power source.

(b) Where long-term storage or disposal provisions are used as a reliability feature, these shall consist of ponds, reservoirs, percolation areas, downstream sewers leading to other treatment or disposal facilities or any other facilities reserved for the purpose of emergency storage or disposal of untreated or partially treated wastewater. These facilities shall be of sufficient capacity to provide disposal or storage of wastewater for at least 20 days, and shall include all the necessary diversion works, provisions for odor and nuisance control, conduits, and pumping and pump back equipment. All of the equipment other than the pump back equipment shall be either independent of the normal power supply or provided with a standby power source.

(c) Diversion to a less demanding reuse is an acceptable alternative to emergency disposal of partially treated wastewater provided that the quality of the partially treated wastewater is suitable for the less demanding reuse.

(d) Subject to prior approval by the regulatory agency, diversion to a discharge point which requires lesser quality of wastewater is an acceptable alternative to emergency disposal of partially treated wastewater.

(e) Automatically actuated short-term retention or disposal provisions and automatically actuated long-term storage or disposal provisions shall include, in addition to provisions of (a), (b), (c), or (d) of this section, all the necessary sensors, instruments, valves and other devices to enable fully automatic diversion of untreated or partially treated wastewater to approved emergency storage or disposal in the event of failure of a treatment process and a manual reset to prevent automatic restart until the failure is corrected.

§ 60343. Primary Treatment.

All primary treatment unit processes shall be provided with one of the following reliability features:

(a) Multiple primary treatment units capable of producing primary effluent with one unit not in operation.

(b) Standby primary treatment unit process.

(c) Long-term storage or disposal provisions.

§ 60345. Biological Treatment.

All biological treatment unit processes shall be provided with one of the following reliability features:

(a) Alarm and multiple biological treatment units capable of producing oxidized wastewater with one unit not in operation.

(b) Alarm, short-term retention or disposal provisions, and standby replacement equipment.

(c) Alarm and long-term storage or disposal provisions.

(d) Automatically actuated long-term storage or disposal provisions.

§ 60347. Secondary Sedimentation.

All secondary sedimentation unit processes shall be provided with one of the following reliability features:

(a) Multiple sedimentation units capable of treating the entire flow with one unit not in operation.

(b) Standby sedimentation unit process.

(c) Long-term storage or disposal provisions.

§ 60349. Coagulation.

(a) All coagulation unit processes shall be provided with the following mandatory features for uninterrupted coagulant feed:

(1) Standby feeders,

(2) Adequate chemical stowage and conveyance facilities,

(3) Adequate reserve chemical supply, and

(4) Automatic dosage control.

(b) All coagulation unit processes shall be provided with one of the following reliability features:

(1) Alarm and multiple coagulation units capable of treating the entire flow with one unit not in operation;

(2) Alarm, short-term retention or disposal provisions, and standby replacement equipment;

(3) Alarm and long-term storage or disposal provisions;

(4) Automatically actuated long-term storage or disposal provisions, or

(5) Alarm and standby coagulation process.

§ 60351. Filtration.

All filtration unit processes shall be provided with one of the following reliability features:

(a) Alarm and multiple filter units capable of treating the entire flow with one unit not in operation.

(b) Alarm, short-term retention or disposal provisions and standby replacement equipment.

(c) Alarm and long-term storage or disposal provisions.

(d) Automatically actuated long-term storage or disposal provisions.

(e) Alarm and standby filtration unit process.

§ 60353. Disinfection.

(a) All disinfection unit processes where chlorine is used as the disinfectant shall be provided with the following features for uninterrupted chlorine feed:

(1) Standby chlorine supply,

(2) Manifold systems to connect chlorine cylinders,

(3) Chlorine scales, and

(4) Automatic devices for switching to full chlorine cylinders.

Automatic residual control of chlorine dosage, automatic measuring and recording of chlorine residual, and hydraulic performance studies may also be required.

(b) All disinfection unit processes where chlorine is used as the disinfectant shall be provided with one of the following reliability features:

(1) Alarm and standby chlorinator;

(2) Alarm, short-term retention or disposal provisions, and standby replacement equipment;

(3) Alarm and long-term storage or disposal provisions;

(4) Automatically actuated long-term storage or disposal provisions; or

(5) Alarm and multiple point chlorination, each with independent power source, separate chlorinator, and separate chlorine supply.

§ 60355. Other Alternatives to Reliability Requirements.

Other alternatives to reliability requirements set forth in Articles 8 to 10 may be accepted if the applicant demonstrates to the satisfaction of the State Department of Health that the proposed alternative will assure an equal degree of reliability.

§ 60400. Certification.

"Certification" means that a water treatment device or a treatment component used in water treatment devices has met the testing requirements specified in section 60435 or the testing requirements accepted by the Department pursuant to section 4057.1 (c) of the Health and Safety Code as defined in section 60440.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Sections 4057 and 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60401. Health and Safety Claim.

(a) "Health or Safety Claim" means one or more of the following:

(1) Any claim that the water treatment device or treatment component will remove or reduce a contaminant for which a primary drinking water standard as defined in Health and Safety Code section 4010.1 or a treatment requirement as authorized in sections 4023.1(c) and 4023.3(d) of the Health and Safety Code has been established.

(2) Any claim that the water treatment device or treatment component will remove or reduce a contaminant for which a national primary drinking water standard or treatment requirement has been established under the U.S. Safe Drinking Water Act (PL 93-523 and as amended under PL 99-339) (42 U.S.C. section 300g-1).

(3) Any claim that the water treatment device or treatment component will remove or reduce a contaminant which has been determined to present a health risk by the United States Environmental Protection Agency pursuant to sections 1445(a)(2) and 1445(a)(3) of the U.S. Safe Drinking Water Act (PL 93-523 and as amended under PL 99-339) (42 U.S.C. section 300j-4(a)(2) and (a)(3)).

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Sections 4010.1 4023.1, 4023.3, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60402. Independent Laboratory.

"Independent Laboratory" means a laboratory that is neither owned or operated by the manufacturer or an entity which is a parent or subsidiary company to the manufacturer of a water treatment device or treatment component nor is in apartnership with the manufacturer or entity which is a parent or subsidiary company to the manufacturer.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Sections 4057 and 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60403. Manufacturer.

(a) "Manufacturer" means any person, as defined by section 4057(c) of the California Health and Safety Code, that makes, converts, constructs, or produces water treatment devices or treatment components for the purpose of sale, lease or rent to individuals, corporations, associations, or other entities. Manufacturer also includes:

(1) Persons that assemble water treatment devices or treatment components from components manufactured by another entity.

(2) Persons who add their own product name or product identification to water treatment devices or treatment components which have been manufactured or assembled by another entity.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Reference: Sections 4057 and 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60404. Recognized Testing Organization.

"Recognized Testing Organization" means an independent laboratory which has been accredited by the Department pursuant to Health and Safety Code, division 1, part 2, chapter 7.5, section 1010 et seq.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Sections 4010.1, 4057 and 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60405. Testing Requirements.

"Testing Requirements" means the contaminant reduction and general performance requirements pursuant to section 60435.

NOTE: Authority Cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Sections 4057 and 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60406. Modification.

"Modification" means any change made to a certified water treatment device or certified treatment component which may affect its performance in meeting the testing requirements or an change in the health or safety claims made with respect to the certified water treatment device or certified treatment component.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Sections 4057 and 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60407. Certification Period.

The certification shall be valid for one year and shall be renewable for a period not to exceed five years.

NOTE: Authority cited: Sections 208, 4057.1 and 4057.2, Health and Safety Code. Reference: Sections 4057.1 and 4057.2, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60410. Certification Application.

(a) Application for certification shall be submitted by the manufacturer for each water treatment device or treatment component.

(b) A completed application shall include the following:

(1) Applicant business name, address, and phone number.

(2) A contact person, address, and phone number.

(3) The identification of each and every specific contaminant for each and every health or safety claim which is made for the water treatment device or treatment component.

(4) Product design specifications and engineering information including blueprints or similar drawing which will provide detailed information about the construction of the water treatment device and treatment components.

(5) Parts list for the water treatment device or treatment component.

(6) Test data and verification as prescribed by section 60435, 60445, 60450 or 60455.

(7) A list of all names, model numbers, or other product identifications which are used by the manufacturer to describe the water treatment device or treatment component.

(8) A statement containing the following declaration by the manufacturer: "This water treatment device or treatment component, which is identified as (insert name, model number, or other product identification) has been toxicologically reviewed and tested to verify that no substances are contributed by the unit to the treated water at levels that would adversely affect the health of the users. The toxicological review and testing was conducted pursuant to the requirements of the material review and qualifications procedures contained in the appropriate testing standard referenced in Table I of section 60435 or Table II of section 60450."

(9) The application shall be signed by a person in a principal management position.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Section 057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60415. Certification Renewal.

(a) A completed application for renewal of a certification shall be submitted by the manufacturer. A completed application shall include the following:

(1) Applicant business name, address, and phone number.

(2) A contact person, address, and phone number.

07739

085336

(3) A written statement that identifies any change to the information provided as described in section 60410(b)(7) and (8) or changes to section 60410(b)(4) and (5) which do not constitute modifications.

(4) The application shall be signed by a person in a principal management position.

(b) The manufacturer shall be responsible for making application for renewal of a certification at least 30 days prior to the expiration date. If the application is submitted after that date, a late application penalty must be paid.

(c) In the event that the application for renewal of the certification is denied by the department, the manufacturer will be notified by registered mail of the denial and the reasons for the denial. The manufacturer may appeal the denial in accordance with Government Code, title 2, division 3, chapter 5, section 11500 et seq. The registered letter providing notice of the denial will be considered the accusation within the appeal process.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Section 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60425. Modification of a Certification.

(a) Any modification made to a certified water treatment device or certified treatment component without the written approval of the Department shall void the certification.

(b) Application to modify an existing certification shall be submitted by the manufacturer. A completed application for the modification of a certified water treatment device or certified treatment component shall include the following:

(1) Applicant business name, address, and telephone number.

(2) Name of a contact person, address, and telephone number.

(3) A statement of the reasons for the modification(s).

(4) A description of the modification(s) to the certified water treatment device or certified treatment component such as changes in the health or safety claims; changes in treatment components; changes in parts which are in direct contact with the influent or product water; or changes to parts which affect the treatment process or product safety.

(6) Changes to the parts list provided pursuant to section 60410(b)(5).

(7) Changes to the product design, specifications and engineering information including blueprints or similar drawings provided pursuant to section 60410(b)(4).

(8) Changes to the list of names, model numbers, or other product identifications provided pursuant to section 60410(b)(7).

(9) A statement containing the following declaration by the manufacturer: "This water treatment device or treatment component, which is identified as (insert name, model number, or other product identification) has been to toxicologically reviewed and tested to verify that no substances are contributed by the unit to the treated water at levels that would adversely affect the health of the users. The toxicological review and testing was conducted pursuant to the requirements of the material review and qualifications procedures contained in the appropriate testing standard referenced in Table I of section 60435 or Table II of section 60450."

(10) The application shall be signed by a person in a principal management position.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Section 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60430. Processing Time.

(a) Within 45 calendar days of receipt of an application for certification, or modification of a certified water treatment device or certified treatment component, the Department shall inform the applicant in writing that the application is complete and accepted for filing, or that it is incomplete and what specific information is needed.

(b) Within 90 calendar days from the date of filing a completed application for certification or modification of a certified water treatment device or certified treatment component, the Department shall inform the applicant in writing of its decision.

(c) Within 30 calendar days of receipt of an application for renewal of certification, the Department shall inform the applicant in writing that the application is complete and accepted for filing, or that it is incomplete and what specific information is needed.

(d) Within 30 calendar days of receipt of a completed application for the renewal of certification, the Department shall inform the applicant in writing that certification has or has not been extended.

NOTE: Authority cited: Section 208, Health and Safety Code; and Section 15376, Government Code. Reference: Section 15376, Government Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60435. Testing and Testing Protocols.

(a) To be considered for certification, a water treatment device or treatment component shall be tested and found to meet the requirements set forth in Table I.

(b) The testing shall be conducted:

(1) By a recognized testing organization; or

(2) By a manufacturer pursuant to section 60445.

(c) All contaminant reduction and general performance testing shall be conducted by a laboratory which has been accredited by the Department pursuant to Health and Safety Code, division 1, part 2, chapter 7.5, section 1010 et seq. Test data submitted pursuant to section 60450 are exempt from this provision.

[2] National Sanitation Foundation Standard 58, Reverse Osmosis Drinking Water Treatment Systems, November 1986.
[3] National Sanitation Foundation Standard 44, Cation Exchange Water Softeners, December 1987.
[4] National Sanitation Foundation Standard 62, Drinking Water Distillation Systems, May 1989.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Section 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60440. Manufacturer's Testing Protocols.

(a) Whenever the testing requirements of Table I of section 60435 are not applicable for the treatment process or the specific contaminant for which certification is requested, the applicant shall submit proposed testing protocols to the Department for approval prior to the testing of the watertreatment device or treatment component.

(b) The proposed testing protocols shall include the following:

(1) Testing shall be conducted in duplicate.

(2) Testing shall be conducted under pressure and flow conditions typical of the end use of the water treatment device or treatment component.

(3) Testing shall provide an equivalent level of assurance that the performance of a water treatment device or treatment component is consistent with the performance of those water treatment or treatment components devices which are tested against the testing requirements prescribed in Table I of section 60435.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Section 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60445. Manufacturer's Test Data.

(a) Test data developed by a manufacturer and submitted to the Department pursuant to the provisions of section 60435(b)(2) shall meet all of the following requirements:

(1) The data was obtained using the testing requirements prescribed in section 60435 or the testing requirements accepted by the Department pursuant to section 4057.1(c) of the Health and Safety Code as defined in section 60440.

(2) The data was produced by a laboratory which is wholly owned by the manufacturer of the water treatment device or treatment component.

(3) The manufacturer has complied with the Department's request for information regarding the qualifications of the laboratory staff, laboratory equipment used for testing and analysis, and records related to the testing under review.

(4) The manufacturer's laboratory has been inspected by the Department's staff under a cost reimbursement agreement to recover the cost incurred to make the inspection(s).

(5) The manufacturer has performed replicate testing, as specified by the Department, during the on-site inspection. Such testing shall be required when test data submitted pursuant to this section is incomplete or there is reasonable doubt regarding the ability of the treatment process to remove or reduce one or more of the specific contaminants tested.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Sections 4057.1, and 4057.2, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60450. Prior Test Data.

When a manufacturer submits prior test data to satisfy the requirements of section 60410(b)(6), the manufacturer shall demonstrate that any test data developed before September 1, 1990 was developed by an independent laboratory or by a manufacturer's laboratory; and that the test data was developed using a testing protocol that was consistent with the applicable testing requirementset forth in Table II. All test data considered by the Department pursuant to this paragraph shall have been produced from testing that was conducted after January 1, 1983.

Table II
Testing Requirements for Prior Data

Treatment Process	Reference Standard	TESTING PROTOCOLS	
		Contaminant Reduction Requirements (Sections)	General Performance Requirements (Sections)
Mechanical Filtration	NSF Standard 53[1]	5.2, 5.2.1, 5.3, 5.3.1, 5.3.2, 5.3.3	4.2, 4.2.1, 4.2.2, 4.2.3, 4.2.4, 4.4, 5.5
Activated Carbon			
Reverse Osmosis	NSF Standard 58[2]	5.3, 5.4, 5.4.1, 5.4.2, 5.4.3	4.1, 4.7.2, 4.7.3
Cation Exchange	NSF Standard 44[3]	5.2, 5.2.1	4.3
Distillation	NSF Standard 62[4]	5.1, 5.2, 5.3	4.21, 4.5, 4.5.1, 4.5.2, 4.5.2.1, 5.4

Notes:

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60455. Extrapolation of Data.

(a) Where a manufacturer has several water treatment devices or treatment components each using the same treatment technology and they are of similar construction, the manufacturer may submit test data developed pursuant to section 60435 or the manufacturer's testing protocol accepted by the Department pursuant to section 4057.1(c) of the Health and Safety Code, as defined in section 60440, on one water treatment device or treatment component as representative of the others under the following conditions:

(1) The manufacturer submits evidence that extrapolation will provide test data that is reasonably consistent with empirical data that would be obtained from the actual testing of the water treatment device or treatment component.

(2) Extrapolation is limited to the scaling or down in size as measured by the volume of product water produced or volume of water to be treated.

(3) Scaling up shall be limited to three times greater than the size of the representative water treatment device or treatment component.

(4) Scaling down shall be limited to one third the size of the representative water treatment device or treatment component.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Section 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60460. Retesting.

(a) The manufacturer shall retest each certified water treatment device or certified treatment component every five years from the date of certification to insure continued compliance with this chapter and shall submit the results to the Department along with the application for recertification.

(b) The manufacturer shall retest a certified water treatment device or certified treatment component for the reduction of a contaminant or for a general performance requirement when the Department determines through testing pursuant to section 60435 or the manufacturer's testing protocol accepted by the Department pursuant to section 4057.1 of the Health and Safety Code, as defined in section 60440, that the water treatment device or treatment component is not meeting a requirement when the water treatment device or treatment component is used according to the manufacturer's instructions. The manufacturer shall comply with the following requirements when retesting pursuant to this paragraph:

(1) Retesting pursuant to subsection (b) shall be conducted by a recognized testing organization in accordance with section 60435 or the manufacturer's testing protocol and shall be initiated within three months of notification by registered mail of the Department's determination.

(2) The results of retesting shall be submitted to the Department within 60 days of initiating the testing.

(3) The results of retesting shall be in conformance with section 60435 or the manufacturer's testing protocol. Manufacturers of certified water treatment devices or certified treatment components determined to be out of compliance with section 60435 or the manufacturer's testing protocol will be notified by registered mail of the decertification and reason for decertification. The manufacturer may appeal the decertification in accordance with Government Code, title 2, division 3, chapter 5, section 11500 et seq. The registered letter providing notice of the decertification will be considered the accusation within the appeal process.

(c) Retesting pursuant to subdivision (a) shall not be required for a certified water treatment device or certified treatment component if the water treatment device or treatment component is listed under a product listing program operated a non-profit third party testing organization and subject to the following provisions:

(1) The listing program is operated by a recognized testing organization.

(2) The listing program includes retesting of the water treatment device or its treatment components at least every five years.

07742

085339

(3) The listing program requires that the manufacturer maintain a quality assurance and quality control program for the manufacturing of the water treatment device or treatment component.

(4) The listing program includes visits at least every two years to the manufacturing plants to inspect the manufacturing of the water treatment device or treatment component and the quality control records maintained by the manufacturer.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Sections 4057.1 and 4057.3, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60465. Product Labeling.

(a) A permanent, clear, and legible plate or label containing the following information shall be securely affixed to each certified water treatment device or certified treatment component so that such plate or label can only be removed with a purposeful effort and the plate or label shall be affixed in a readily accessible location:

(1) Equipment name.

(2) Model designation.

(3) Name of manufacturer.

(4) The statement "For conditions of use, health claims certified by the California Department of Health Services, and replacement parts, see product data sheet."

(5) The statement "California Department of Health Services Certification Number: XXXXXX."

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Section 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60470. Product Data Sheet.

(a) Each certified water treatment device shall be accompanied by a Product Data Sheet which includes the following information:

(1) A copy of the certificate by which the Department has granted certification of the water treatment device. The copy may be incorporated in the product data sheet or attached to the sheet.

(2) Service flow rate in gallons per minute or gallons per day (Liters/day) or the production rate in gallons per day (Liters/day).

(3) Rated service life of the water treatment device (where applicable).

(4) General use conditions and needs, such as maximum turbidity and bacteriological quality of source water.

(5) Model or part number and estimated cost of components that must be periodically or routinely, replaced to maintain the effectiveness of the certified water treatment device.

(6) Maximum and minimum operating temperature in degrees Fahrenheit and degrees Centigrade.

(7) Maximum and minimum operating pressure in pounds per square inch and kilograms per square centimeter.

(8) A reference to the owner's manual for general operation and maintenance requirements, and the manufacturer's warranty.

NOTE: Authority cited: Sections 208 and 4057.1, Health and Safety Code. Reference: Section 4057.1, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

§ 60475. Fees.

(a) The fees specified shall be paid pursuant to the requirements of this chapter. The fees paid are non-refundable:

(1) Certification or Recertification	$1,400
(2) Annual Renewal	$ 400
(3) Late Renewal Penalty	$ 200
(4) Modification of a Certification	$ 300

NOTE: Authority cited: Sections 208, 4057.1 and 4057.5, Health and Safety Code. Reference: Section 4057.5, Health and Safety Code.

HISTORY

1. New section filed 9-6-90; operative 10-6-90 (Register 90, No. 43).

Chapter 14. Water Permits

Article 1. Applications

§ 64001. Water Permit Application.

(a) Within 30 calendar days of receipt of an application for a permit or petition for permit modification pursuant to Section 4011 or 4019, Health and Safety Code, the Department shall inform the applicant in writing that it is either complete and accepted for filing or that it is deficient and what specific information or documentation is required to complete the application. An application is considered complete if it is in compliance with the requirements of Section 4012, Health and Safety Code. For proposed water system improvements, new water systems or a "project" as defined in Section 15378, Title 14, California Administrative Code where environmental documentation is required, a copy of such documentation shall be included in the application.

(b) Within 90 calendar days from the date of filing of a completed application, the Department shall inform the applicant in writing of its decision regarding an application.

NOTE: Authority cited: Section 15376, Government Code; and Sections 4011, 4012 and 4019, Health and Safety Code. Reference: Section 15376, Government Code; and Sections 21000–21176, Public Resources Code.

HISTORY

1. New Chapter 14 (Sections 64001 and 64002) filed 7-14-86; effective thirtieth day thereafter (Register 86, No. 29).

§ 64002. Processing Time.

The Department's time periods for processing an application from the receipt of the initial application to the final decision regarding issuance or denial of a water permit based on the Department's actual performance during the two years preceding the proposal of this section, were as follows:

(a) The median time was—7.5 months

(b) The minimum time was—1.5 months

(c) The maximum time was—85.5 months

NOTE: Authority cited: Section 15376, Government Code; and Sections 4011 and 4019, Health and Safety Code. Reference: Section 15376, Government Code; and Sections 21000–21176, Public Resources Code.

HISTORY

1. New section filed 7-14-86; effective thirtieth day thereafter (Register 86, No. 29).

Chapter 15. Domestic Water Quality and Monitoring

Article 1. Purpose and Responsibility

§ 64401. Purpose.

(a) These regulations establish primary and secondary drinking water standards for public water systems, including minimum water quality monitoring of water delivered to consumers, pursuant to Sections 4010–4037, Health and Safety Code.

(b) Primary drinking water standards contained in these regulations are based upon the National Interim Primary Drinking Water Regulations, 40 CFR Part 141, and shall be met by all public water systems, subject to any current variance, exemption or other authorized exception.

(c) Secondary drinking water standards contained in these regulations are based upon the National Secondary Drinking Water Regulations, 40 CFR Part 143, and shall be met by all public water systems, subject to any current waiver or other authorized exception.

(d) Requests for variances or exemptions from certain maximum contaminant levels of the primary drinking water standards shall be considered by the Department in accordance with Section 4021, Health and Safety Code. Procedures for consideration and granting of variances and

Article 2. Protection of Water System

Article 3. Domestic Water Supply Reservoirs

Article 1. General

7583. Definitions.

In addition to the definitions in Section 4010.1 of the Health and Safety Code, the following terms are defined for the purpose of this Chapter:

(a) "Approved Water Supply" is a water supply whose potability is regulated by a State or local health agency.

(b) "Auxiliary Water Supply" is any water supply other than that received from a public water system.

(c) "Air-gap Separation (AG)" is a physical break between the supply line and a receiving vessel.

(d) "AWWA Standard" is an official standard developed and approved by the American Water Works Association (AWWA).

(e) "Cross-Connection" is an unprotected actual or potential connection between a potable water system used to supply water for drinking purposes and any source or system containing unapproved water or a substance that is not or cannot be approved as safe, wholesome, and potable. By-pass arrangements, jumper connections, removable sections, swivel or changeover devices, or other devices through which backflow could occur, shall be considered to be cross-connections.

(f) "Double Check Valve Assembly (DC)" is an assembly of at least two independently acting check valves including tightly closing shut-off valves on each side of the check valve assembly and test cocks available for testing the watertightness of each check valve.

(g) "Health Agency" means the California Department of Health Services, or the local health officer with respect to a small water system.

(h) "Local Health Agency" means the county or city health authority.

(i) "Reclaimed Water" is a wastewater which as a result of treatment is suitable for uses other than potable use.

(j) "Reduced Pressure Principle Backflow Prevention Device (RP)" is a backflow preventer incorporting not less than two check valves, an automatically operated differential relief valve located between the two check valves, a tightly closing shut-off valve on each side of the check valve assembly, and equipped with necessary test cocks for testing.

(k) "User Connection" is the point of connection of a user's piping to the water supplier's facilities.

(*l*) "Water Supplier" is the person who owns or operates the public water system.

(m) "Water User" is any person obtaining water from a public water supply.

NOTE: Authority cited: Sections 208 and 4026, Health and Safety Code. Reference: Section 4026, Health and Safety Code.

HISTORY:

1. Repealer of Articles 1 through 10 and New Articles 1 through 4 (Sections 7583, 7588 through 7594, 7603 through 7605, and 7615 through 7622) filed 5-8-53; effective thirtieth day thereafter (Register 53, No. 8).
2. New section filed 5-26-87; operative 6-25-87 (Register 87, No. 23).

T17-7583. Purpose.

NOTE: Authority cited: Sections 208 and 4026, Health and Safety Code. Reference: Section 4026, Health and Safety Code.

HISTORY:

1. Repealer filed 5-26-87; operative 6-25-87 (Register 87, No. 23).

07746

085343

7584. Responsibility and Scope of Program.

The water supplier shall protect the public water supply from contamination by implementation of a cross-connection control program. The program, or any portion thereof, may be implemented directly by the water supplier or by means of a contract with the local health agency, or with another agency approved by the health agency. The water supplier's cross-connection control program shall for the purpose of addressing the requirements of Sections 7585 through 7605 include, but not be limited to, the following elements:

(a) The adoption of operating rules or ordinances to implement the cross-connection program.

(b) The conducting of surveys to identify water user premises where cross-connections are likely to occur,

(c) The provisions of backflow protection by the water user at the user's connection or within the user's premises or both,

(d) The provision of at least one person trained in cross-connection control to carry out the cross-connection program,

(e) The establishment of a procedure or system for testing backflow preventers, and

(f) The maintenance of records of locations, tests, and repairs of backflow preventers.

NOTE: Authority cited: Sections 208 and 4026, Health and Safety Code. Reference: Section 4026, Health and Safety Code.

HISTORY:

1. New section filed 5-26-87; operative 6-25-87 (Register 87, No. 23).

7585. Evaluation of Hazard.

The water supplier shall evaluate the degree of potential health hazard to the public water supply which may be created as a result of conditions existing on a user's premises. The water supplier, however, shall not be responsible for abatement of cross-connections which may exist within a user's premises. As a minimum, the evaluation should consider: the existence of cross-connections, the nature of materials handled on the property, the probability of a backflow occurring, the degree of piping system complexity and the potential for piping system modification. Special consideration shall be given to the premises of the following types of water users:

(a) Premises where substances harmful to health are handled under pressure in a manner which could permit their entry into the public water system. This includes chemical or biological process waters and water from public water supplies which have deteriorated in sanitary quality.

(b) Premises having an auxiliary water supply, unless the auxiliary supply is accepted as an additional source by the water supplier and is approved by the health agency.

(c) Premises that have internal cross-connections that are not abated to the satisfaction of the water supplier or the health agency.

(d) Premises where cross-connections are likely to occur and entry is restricted so that cross-connection inspections cannot be made with sufficient frequency or at sufficiently short notice to assure that cross-connections do not exist.

(e) Premises having a repeated history of cross-connections being established or re-established.

NOTE: Authority cited: Sections 208 and 4026, Health and Safety Code. Reference: Section 4026, Health and Safety Code.

HISTORY:

1. New section filed 5-26-87; operative 6-25-87 (Register 87, No. 23).

7586. User Supervisor.

The health agency and water supplier may, at their discretion, require an industrial water user to designate a user supervisor when the water user's premises has a multipiping system that convey various types of fluids, some of which may be hazardous and where changes in the piping system are frequently made. The user supervisor shall be responsible for the avoidance of cross-connections during the installation, operation and maintenance of the water user's pipelines and equipment.

HISTORY:

1. Repealer filed 5-26-87; operative 6-25-87 (Register 87, No. 23).

Article 2. Protection of Water System

7601. Approval of Backflow Preventers.

Backflow preventers required by this Chapter shall have passed laboratory and field evaluation tests performed by a recognized testing organization which has demonstrated their competency to perform such tests to the Department.

NOTE: Authority cited: Sections 208 and 4026, Health and Safety Code. Reference: Section 4026, Health and Safety Code.

HISTORY:

1. New section filed 5-26-87; operative 6-25-87 (Register 87, No. 23).

7602. Construction of Backflow Preventers.

(a) Air-gap Separation. An Air-gap separation (AG) shall be at least double the diameter of the supply pipe, measured vertically from the flood rim of the receiving vessel to the supply pipe; however, in no case shall this separation be less than one inch.

(b) Double Check Valve Assembly. A required double check valve assembly (DC) shall, as a minimum, conform to the AWWA Standard C506-78 (R83) adopted on January 28, 1978 for Double Check Valve Type Backflow Preventive Devices which is herein incorporated by reference.

(c) Reduced Pressure Principle Backflow Prevention Device. A required reduced pressure principle backflow prevention device (RP) shall, as a minimum, conform to the AWWA Standard C506-78 (R83) adopted on January 28, 1978 for Reduced Pressure Principle Type Backflow Prevention Devices which is herein incorporated by reference.

NOTE: Authority cited: Sections 208 and 4026, Health and Safety Code. Reference: Section 4026, Health and Safety Code.

HISTORY:

1. New section filed 5-26-87; operative 6-25-87 (Register 87, No. 23).

7603. Location of Backflow Preventers.

(a) Air-gap Separation. An air-gap separation shall be located as close as practical to the user's connection and all piping between the user's connection and the receiving tank shall be entirely visible unless otherwise approved in writing by the water supplier and the health agency.

(b) Double Check Valve Assembly. A double check valve assembly shall be located as close as practical to the user's connection and shall be installed above grade, if possible, and in a manner where it is readily accessible for testing and maintenance.

(c) Reduced Pressure Principle Backflow Prevention Device. A reduced pressure principle backflow prevention device shall be located as close as practical to the user's connection and shall be installed a minimum of twelve inches (12") above grade and not more than thirty-six inches (36") above grade measured from the bottom of the device and with a minimum of twelve inches (12") side clearance.

NOTE: Authority cited: Sections 208 and 4026, Health and Safety Code. Reference: Section 4026, Health and Safety Code.

HISTORY:

1. New section filed 5-26-87; operative 6-25-87 (Register 87, No. 23).

7604. Type of Protection Required.

The type of protection that shall be provided to prevent backflow into the public water supply shall be commensurate with the degree of hazard that exists on the consumer's premises. The type of protective device that may be required (listed in an increasing level of protection) includes: Double Check Valve Assembly—(DC), Reduced Pressure Principle Backflow Prevention Device—(RP), and an Air-gap Separation—(AC). The water user may choose a higher level of protection than required by the water supplier. The minimum types of backflow protection required to protect the public water supply, at the water user's connection to premises with various degrees of hazard are given in Table 1. Situations which are not covered in Table 1 shall be evaluated on a case-by-case basis and the appropriate backflow protection shall be determined by the water supplier or health agency.

TABLE 1

TYPE OF BACKFLOW PROTECTION REQUIRED

Degree of Hazard	*Minimum Type of Backflow Prevention*
(a) Sewage and Hazardous Substances	
(1) Premises where the public water system is used to supplement the reclaimed water supply.	AC
(2) Premises where there are wastewater pumping and/or treatment plants and there is no interconnection with the potable water system. This does not include a single-family residence that has a sewage lift pump. A RP may be provided in lieu of an AC if approved by the health agency and water supplier.	AC
(3) Premises where reclaimed water is used and there is no interconnection with the potable water system. A RP may be provided in lieu of an AC if approved by the health agency and water supplier.	AC
(4) Premises where hazardous substances are handled in any manner in which the substances may enter the potable water system. This does not include a single-family residence that has a sewage lift pump. A RP may be provided in lieu of an AC if approved by the health agency and water supplier.	AC
(5) Premises where there are irrigation systems into which fertilizers, herbicides, or pesticides are, or can be, injected.	RP
(b) Auxiliary Water Supplies	
(1) Premises where there is an unapproved auxiliary water supply which is interconnected with the public water system. A RP or DC may be provided in lieu of an AC if approved by the health agency and water supplier.	AC
(2) Premises where there is an unapproved auxiliary water supply and there are no interconnections with the public water system. A DC may be provided in lieu of a RP if approved by the health agency and water supplier.	RP
(c) Fire Protection Systems	
(1) Premises where the fire system is directly supplied from the public water system and there is an unapproved auxiliary water supply on or to the premises (not interconnected).	DC

(2) Premises where the fire system is supplied from the public water system and interconnected with an unapproved auxiliary water supply. A RP may be provided in lieu of an AC if approved by the health agency and water supplier. AC

(3) Premises where the fire system is supplied from the public water system and where either elevated storage tanks or fire pumps which take suction from private reservoirs or tanks are used. DC

(d) Dockside Watering Points and Marine Facilities DC

(1) Pier hydrants for supplying water to vessels for any purpose. RP

(2) Premises where there are marine facilities. RP

(e) Premises where entry is restricted so that inspections for cross-connections cannot be made with sufficient frequency or at sufficiently short notice to assure that cross-connections do not exist. RP

(f) Premises where there is a repeated history of cross-connections being established or re-established. RP

NOTE: Authority cited: Sections 208 and 4026, Health and Safety Code. Reference: Section 4026, Health and Safety Code.

HISTORY:

1. New section filed 5-26-87; operative 6-25-87 (Register 87, No. 23).

7605. Testing and Maintenance of Backflow Preventers.

(a) The water supplier shall assure that adequate maintenance and periodic testing are provided by the water user to ensure their proper operation.

(b) Backflow preventers shall be tested by persons who have demonstrated their competency in testing of these devices to the water supplier or health agency.

(c) Backflow preventers shall be tested at least annually or more frequently if determined to be necessary by the health agency or water supplier. When devices are found to be defective, they shall be repaired or replaced in accordance with the provisions of this Chapter.

(d) Backflow preventers shall be tested immediately after they are installed, relocated or repaired and not placed in service unless they are functioning as required.

(e) The water supplier shall notify the water user when testing of backflow preventers is needed. The notice shall contain the date when the test must be completed.

(f) Reports of testing and maintenance shall be maintained by the water supplier for a minimum of three years.

Article 5. Domestic Water Supply Reservoirs

7623. Intent of Regulations.

These regulations are intended to provide safeguards on domestic water supply reservoirs as part of the program to insure that water being furnished for domestic purposes is such that under all the circumstances and conditions it is pure, wholesome and potable, and does not endanger the lives or health of human beings.

NOTE: Authority cited for Article 5 (§§ 7623 through 7630): Sections 102, 203, 208, and 4010 through 4035, Health and Safety Code.

HISTORY:

1. New Article 5 (§§ 7623 through 7630) filed 12-14-56; effective thirtieth day thereafter (Register 56, No. 22).

7624. Application of Regulations.

These regulations are intended to be strictly applied to domestic water supply reservoirs operated by a domestic water purveyor and used solely or primarily for domestic water supply.

7625. Definitions.

The term "domestic water supply reservoir" as used herein means a reservoir used to impound or store water intended solely or primarily for domestic purposes.

The term "domestic water purveyor" means any person, corporation, public utility, municipality, district or other agency or institution furnishing or supplying water for domestic purposes to two or more places of human habitation by means of an integrated pipe system.

The term "distribution reservoir" as used herein means a reservoir, directly connected with the distribution system of the domestic water supply project, used primarily to care for fluctuations in demand which occur over short periods of from several hours to several days, or as local storage in case of emergency such as a break in a main supply line or failure of pumping plant.

The term "approved dual chlorination" as used herein means the application of chlorine to water by two independently operated chlorine feed installations, such installations having independent sources of power and chlorine, and independent regulation of chlorine feed. The points of chlorine feed from the two chlorinators should be separated so that the second application of chlorine will be after the full effect of the first chlorination has taken place. Rates of chlorine feed of each machine must be sufficient to provide disinfection of the flow to be treated.

7626. Application for Permit.

Any domestic water purveyor planning to allow recreational use on and around a domestic water supply reservoir, or proposing to continue the use of a domestic water supply reservoir on or around which recreation is now practiced without specific authorization in an existing water supply permit, shall submit an application for permit or for permit amendment to the State Department of Public Health.

7627. Data to Accompany Application.

Such application shall be accompanied by a detailed plan, including maps, showing the reservoir area and location of appurtenant facilities, a statement describing the details of the intended recreational use, a description of the

07753

085350

program for regulating use of the area, plans and description of the recreational and sanitary facilities to be provided, detailed description of maintenance and operation of these facilities and supervision of the people permitted in the area, the numbers of people to be allowed to use the recreational area and facilities, and procedures to control number of users. Such detailed plan shall have been approved by the governing board of the water purveyor.

7628. Guides to Evaluating Application.

In evaluating such application, the department shall be guided by the following considerations:

(1) The size of reservoir, length of time of storage in the reservoir, topography of the reservoir site, prevalence of wind-induced currents, and other factors which may induce short-circuiting of flows in the reservoir;

(2) Size of protective zone between area of recreational use of water surface, and point of withdrawal of water from the reservoir for domestic use;

(3) Type of facilities to provide treatment of water from the reservoir (no permit shall be granted unless the facilities can provide continuous and dependable disinfection);

(4) Maximum number of people to be allowed in the area at any time;

(5) Adequacy of toilet and other sanitation facilities for recreational users;

(6) Program, personnel, and financing to control the public recreational use. For this item, before permit will be granted an agreement in writing must be provided by the water purveyor and the local health department or departments having jurisdiction over the area assuring that adequate public health supervision of the recreational area and facilities will be provided.

7629. Reservoirs for Which Permits May Be Granted.

When the department finds that the intended recreational use will not render the water supply as delivered to the consumers impure, unwholesome or unpotable, permit for such use will be issued. Subject to the department findings the following types of domestic water supply reservoirs may be used for recreational purposes:

(1) Reservoirs from which water is continuously and reliably treated by filtration and chlorination; provided that for smaller water systems, under special circumstances satisfactory to the State Department of Public Health, approved dual chlorination may be acceptable;

(2) Reservoirs from which water is withdrawn by open channels or other conduits and subsequently stored again in reservoirs falling in the category of Section 7629 (1) before reaching a distribution reservoir, or before entering the distribution system or a consumer's premises.

7630. Kinds of Recreational Use Allowed or Prohibited.

Recreational use of domestic water supply reservoirs and shoreline areas shall be limited to fishing, boating, picnicking, hiking and such other recreational uses, exclusive of activities involving bodily contact with the water by persons or animals, as shall be acceptable to the State Department of Public Health. Recreational use of distribution reservoirs is prohibited.

Article 11. Delegation of Authority Pursuant to Section 4025 of the Health and Safety Code (Permits for Small Water Systems)

1. Repealer of Article 12 (Sections 7695-7701) filed 1-31-74; effective thirtieth day thereafter (Register 74, No. 5). For history of prior Article, see Register 53, No. 10.

APPENDIX D

State Guidelines

07756

085353

Guideline for the Preparation of an Engineering Report on the Production, Disinfection, and Use of Reclaimed Water

07757

085354

June 10, 1988

STATE OF CALIFORNIA
DEPARTMENT OF HEALTH SERVICES
ENVIRONMENTAL MANAGEMENT BRANCH

GUIDELINE FOR THE PREPARATION OF AN ENGINEERING REPORT ON THE PRODUCTION, DISTRIBUTION, AND USE OF RECLAIMED WATER

1.0 INTRODUCTION

The Wastewater Reclamation Criteria require the submission of an engineering report to the Regional Water Quality Control Board and the Department of Health Services before wastewater reclamation projects are implemented. The report shall be amended prior to any modification to the project. The report shall describe the manner by which the projects will comply with the Wastewater Reclamation Criteria and conform to the Guidelines for Use of Reclaimed Water. The Wastewater Reclamation Criteria are contained in Sections 60301 to 60355, inclusive, of the California Administrative Code, Title 22, and prescribe:

- Reclaimed water quality and wastewater treatment requirements for the various forms of use of reclaimed water, and
- Reliability features required for the treatment facilities to ensure safe performance.

Section 60323 of the Wastewater Reclamation Criteria specifies that the report be prepared by a properly qualified engineer, registered in California and experienced in the field of wastewater treatment.

Reclamation projects vary in complexity. Therefore, reports will vary in content, and the detail presented will depend on the scope of the proposed project and the number and nature of the agencies involved in the production, distribution, and use of the reclaimed water. The report must contain sufficient information to assure the regulatory agencies that the degree of treatment and reliability is commensurate with the proposed use, and that the distribution and use of the reclaimed water will not create a health hazard or nuisance.

2.0 PRODUCER

The producer is the public or private entity that will treat the wastewater used in the project. Where more than one agency is involved in the treatment, the responsibilities of each agency must be described.

2.1 Reclaimed Water

State the treatment processes and quality of water that are required and will be provided for each use.

2.2 Raw Wastewater

2.21 State the chemical quality.
2.22 State the proportion and type of industrial waste.

2.3 Treatment Processes

2.31 Provide a schematic of the treatment train.

2.32 Describe the treatment processes and the loading rates and/or contact times. All filtration design criteria must be provided (filtration and backwash rates, filter depth and media specifications). The expected turbidities of the filter influent (prior to the addition of chemicals) and the filter effluent must be stated.

2.33 State the chemicals that will be used, the method of mixing, the point of application, and the dosages.

2.4 Plant Reliability Features

The plant reliability features proposed to comply with Sections 60333 - 60355 of the Wastewater Reclamation Criteria must be described in detail. The discussion of each reliability feature must state under what conditions it will be actuated. When alarms are used to indicate system failure the report must state where the alarm will be received, how the location is manned, and who will be notified. The report must state the hours the plant will be manned.

2.5 Supplemental Water Supply

The report must describe all supplemental water supplies. The description must include:

- Source
- Quality
- Quantity available

2.6 Monitoring

The report must describe a monitoring program that complies with the Wastewater Reclamation Criteria, and includes the frequency and location of sampling. Where continuous analyses and recording equipment is used, the method and frequency of calibration must be stated. All analyses shall be performed by a laboratory approved by the State Department of Health Services.

2.7 Contingency Plan

Section 60323 (c) of the Wastewater Reclamation Criteria requires that the engineering report contain a contingency plan designed to prevent inadequately treated wastewater from being delivered to the user. The "Contingency Plan" must include:

- A list of conditions which would require an immediate diversion to take place;
- A description of the diversion procedures;
- Designation of the diversion area;
- A plan for the disposal or treatment of any inadequately treated effluent;

• A plan for notifying the reclaimed water user, the regional board, the state and local health departments, and other agencies as appropriate of any treatment failures that could result in the delivery of inadequately treated wastewater to the use area.

3.0 TRANSMISSION AND DISTRIBUTION SYSTEMS

Maps showing the location of the transmission facilities and the distribution system layout must be provided. The plans must include the location of all water and sewer lines. The report must describe how the transmission and distribution systems will comply with the following documents:

- Guidelines for the Distribution of Non-potable Water, California-Nevada Section AWWA
- Guidelines for Use of Reclaimed Water (DOHS)
- Regulations Relating to Cross-Connections (Title 17, Chapter 5, Subchapter 1)
- Manual of Cross Connection Control / Procedures and Practices (DOHS)

Any deviation from the above, and the necessity therefore, must be discussed in the report.

4.0 USE AREAS

4.1 Use Area Description

The description of each use area must include:

- The land use;
- The type of reuse proposed;
- The party responsible for the distribution and use of the reclaimed water at the site;
- A map showing:
  - ¬ Specific areas of use
  - ¬ Areas of public access
  - ¬ Surrounding land use
  - ¬ The location of wells in or near the use area

07760

085357

In addition to the general information, the following must be provided for these specific proposed uses:

- Irrigation
  - ¬ Type of irrigation (e.g. landscape, specific food crop)
  - ¬ Method of irrigation (e.g. spray, flood, drip)
  - ¬ The location of domestic water supply facilities in or adjacent to the use area
  - ¬ The depth to groundwater underlying the use area and a description of the quality
  - ¬ The direction of drainage and a description of the area to which the drainage will flow
  - ¬ For spray irrigation a wind rose or the best available wind data are needed
  - ¬ The proposed irrigation schedule

- Impoundments
  - ¬ The type of recreational activity to be allowed on the impoundment
  - ¬ The conditions under which the impoundment can be expected to overflow and the expected frequency
  - ¬ The direction of drainage and a description of the area to which the drainage will flow
  - ¬ The depth to groundwater underlying the use area and a description of the quality and use of the groundwater
  - ¬ A description of the soil profile underlying the use area

- Cooling
  - ¬ Type of cooling system
  - ¬ A wind rose or the best available wind data

- Groundwater Recharge
  - ¬ The appropriate information shall be determined on a case by case basis

- Other Industrial Uses
  - ¬ The appropriate information shall be determined on a case by case basis

4.2 Use Area Design

The report must discuss how the facilities will be designed to minimize the chance of reclaimed water leaving the designated use area. The design must be in conformance with the Guidelines for Use of Reclaimed Water. Any proposed deviation from the Guidelines, and the necessity therefore, must be discussed in the report. Any domestic water distribution system shall be protected from the reclaimed water in accordance with the Regulations Relating To Cross Connections.

4.3 Use Area Inspections and Monitoring

Identify the locations at the use area where problems are most likely to occur (e.g. ponding, runoff, overspray) and propose a program of inspection and reporting.

This manual has been accepted by the Water and Bathing Committee of the California Conference of Directors of Environmental Health and the Backflow Problems Committee of the California-Nevada Section, AWWA.

This manual was prepared using material from:

1. *Cross-Connection Control Committee*, Pacific Northwest Section AWWA Manual of Accepted Procedures and Practices.
2. *Manual of Cross-Connection Control* by Foundation for Cross-Connection Control and Hydraulic Research, University of Southern California.
3. *Cross-Connection Control Manual* of the Santa Barbara County Water Purveyors and Department of Health Care Services.
4. *Recommended Practice for Backflow Prevention and Cross-Connection Control*, AWWA Manual M14.
5. *Cross-Connection Control*, British Columbia Section, American Water Works Association.

FOREWORD

The major goal of the California Department of Health Services, Sanitary Engineering Section, is the distribution of a safe and potable water supply to all domestic water users. To accomplish this goal, it is essential that the water and health agencies provide a dynamic cross-connection control program. Therefore, this manual has been prepared to provide the water purveyor, the health departments, and those associated with maintaining a safe, potable supply the information necessary for proper cross-connection control.

The importance of developing and maintaining an ongoing cross-connection control program must be recognized. Backflow through unprotected cross-connections is a major cause of waterborne disease outbreaks. Between 1946 and 1970, distribution system deficiencies (cross-connections) caused more waterborne disease outbreaks in the United States than any other reported factor.[1] From 1971 to 1974, these problems caused 32 percent of all confirmed waterborne disease outbreaks involving municipal water systems. This was again the leading single cause of all outbreaks.[2] In 1975 to 1976, cross-connections were responsible for 47 percent of the disease outbreaks in municipal water systems.[3]

Outbreaks caused by cross-connections are probably much more prevalent than disease statistics indicate. Unreported waterborne disease outbreaks are estimated to occur at least two to three, and perhaps ten, times as frequently as actually reported and documented. For example, outbreaks that affect only small areas are far less likely to be detected than systemwide outbreaks caused by source contamination or treatment deficiencies. Health department officials and system operators and those associated with the distribution of water to consumers must recognize that public health protection requires sound cross-connection control and that establishing and maintaining adequate cross-connection control programs must be a high priority.

The State of California's "Regulations Relating to Cross-Connections," Title 17, California Administrative Code, are by necessity quite general and do not spell out the details of an acceptable cross-connection control program. This manual is intended as a guide in establishing adequate cross-connection control programs. An acceptable cross-connection control program should be carried out in conjunction with water distribution system facilities improvement plans to provide adequate distribution system pressure to minimize the hazards of undetected cross-connections.

LIST OF FIGURES

I. INTRODUCTION

The purpose of this manual is to assist local officials in establishing a cross-connection control program. Implementing an effective cross-connection control program requires the full cooperation of water users, water suppliers, health agencies, plumbing officials, and water supervisors. Each must carry his share of a coordinated cross-connection control program in order to prevent contamination of the potable water supply. If the drinking water system on a premises is found to be contaminated, the health agency and/or the water supplier should be promptly notified and appropriate measures taken to eliminate the contamination. The responsibilities of the entities are outlined below..

A. *Water User* (Property Owner or Consumer)

The water user has the primary responsibility to keep contaminants out of the potable water system(s). This responsibility begins at the user connection and includes any and all water distribution piping on the premises. If a cross-connection or potential for a cross-connection exists the water user, at his own expense, should install, have tested, and maintain approved backflow preventers as directed by the health agency or the water supplier. The water user should prevent the creation of a cross-connection by modifications of the plumbing system.

B. *Water Supplier*

The water supplier has the responsibility to prevent contamination of the public water system by backflow. This responsibility begins at the source and includes the entire water supplier distribution system and ends at the user connection. The water supplier should not provide water service to premises where a cross-connection exists. The water supplier has the responsibility for promulgating and enforcing laws, rules, regulations, and policies necessary to carry out their responsibilities. The water supplier should maintain adequate pressure throughout the system at all times to minimize the hazards of a cross-connection.

C. *Health Agencies*

The health agency also has the responsibility for promulgating and enforcing laws, rules, regulations, and policies to be followed in controlling cross-connections. The agency has the responsibility to insure that internal protection is provided and water utilities maintain an adequate cross-connection control program.

D. *Plumbing Officials*

The plumbing official has the responsibility for the enforcement of plumbing regulations concerned with preventing cross-connections.

E. *Water Supervisor*

The health agency or water supplier may, where appropriate, require a water user to designate a water supervisor to be responsible for the cross-connection control program within the water user's premises. This water supervisor shall review the installation and use of pipelines and equipment to assure that cross-connections are eliminated. Close control of water system piping by a water supervisor adequately trained in cross-connection control will eliminate or reduce the hazards of contamination of the water supply.

II. EXAMPLES OF CROSS-CONNECTION CONTROL PROGRAMS

The purpose of cross-connection control is to protect the public against backflow and back-siphonage of contamination occurring within both public water systems and individual premises. This objective requires that cross-connection control be applied within premises and at service connections from water suppliers. In many cases this internal protection will eliminate the need for meter protection.

In California, three different approaches reflecting local conditions have been developed to meet these needs.

A. *Local Agency Coordinated Program*

Under this program the local health agency assumes responsibility for coordinating the cross-connection control activities of the local health agency, water suppliers, and water users. The health agency reviews certain building plans and specifications, determines where and how cross-connection protection is best provided, sends testing notices, verifies that necessary testing has been completed, and conducts needed follow-ups. The water supplier assists in reviewing plans and specifications and participates in field inspections and enforcement activities.

B. *Water Supplier Contract Program*

Under this program, water suppliers have joined together to contract with a local health agency for the services of competent cross-connection control inspectors. These persons are responsible for conducting a cross-connection control program for the suppliers and health agency. Since this staff is employed by the local agency, both internal protection and premises isolation are provided. This approach works well in areas where there are many small utilities that individually are unable to support a full-time qualified person. This procedure could also be adapted to multicounty arrangements.

C. *Independent Approach*

Under this approach the local health agency and the water supplier work largely independently. Problems created by this approach may involve unnecessary expense to water users when water suppliers require installation of large devices at service connections when a smaller device used on selected internal lines would suffice. There could also be considerable duplication of effort by all concerned. There have been numerous instances where the local agency and the water supplier required duplicate reports and indicated conflicting requirements to the user. These problems can be mitigated by close coordination between the water supplier and the health agency.

III. WHERE PROTECTION IS REQUIRED

A. *Premises Isolation*

Premises isolation is used to protect the public water supply where there are actual or potential cross-connection hazards on the property. Under this philosophy, the entire premises is separated from the public water system by an approved backflow preventer. This protection is necessary if the potential health hazard is severe or if a high probability exists that piping within a premises will be changed. If inspection of the premises is restricted, the only acceptable protection for the water supplier is the installation of a backflow preventer at the user connection. However, this does not protect the people on the premises.

B. *Internal Protection*

Where the agency responsible for carrying out the cross-connection control program has access to the premises for inspection, internal protection is preferred because the people within the premises are protected and in many cases the device can be smaller and less expensive due to smaller plant piping.

Internal protection consists of area isolation and/or protection at the fixture. Protection at the fixture is installing an approved backflow preventer at the source of the potential contamination. Area isolation in confining the potential source of the contamination within a specific area. Industrialization of piping within a premises is an acceptable form of area isolation. Internal cross-connections might be eliminated by changes in the piping within the premises.

Where severe hazards or complex situations exist within the premises, internal protection should be supplemented by premises isolation.

C. *Severe Health Hazard*

There are some facilities where a severe health risk to the public and the water supplier's system exists. In this situation, both internal protection and premises isolation should be provided. A sewage treatment plant, an area where reclaimed sewage is handled under pressure, or an industry where toxic chemicals are handled under pressure are examples of this situation.

D. *Installation Requiring Continuing Service*

Whenever a user requires continuous, uninterrupted service and it is not possible to provide water service from two separate meters, provisions should be made for the installation of two approved backflow preventers in parallel. The two devices together should have the capacity to maintain the flow rate of the single service pipe.

IV. ELEMENTS OF A CROSS-CONNECTION CONTROL PROGRAM

When implementing a cross-connection control program, the water supplier or health agency should follow an organized plan. The following items should be included as a minimum:

A. A city, county, or district should enact an ordinance outlining the cross-connection control program and providing enforcement authority. For investor-owned utilities, appropriate rules of service should be enacted.

B. Specific units of the health agency and/or water supplier should be delegated the responsibility and authority to organize and carry out the cross-connection control program. The personnel in those units should be trained as to the causes and hazards of unprotected cross-connections.

C. All existing facilities where cross-connections are suspected should be listed and inspected or reinspected on a priority basis.

D. All applications for new services or for enlarging existing services should be reviewed or screened for cross-connection hazards before construction.

E. A list of approved backflow preventers and a list of certified testers should be made available to each water user required to provide backflow protection.

F. Backflow preventers should be tested as required by the health agency or water supplier.

G. Adequate records should be kept and filed for reference. These records should include, in addition to the name of the owner of the premises, the:

1. Date of inspection,
2. Results of inspection,
3. Required protection,
4. List of all backflow preventer devices in the system,
5. Test and maintenance reports, and
6. All correspondence between the water supplier, the local health authority, and the consumer.

H. Records of inspection and testing should be evaluated to determine if:

1. Devices are frequently or sufficiently reviewed to detect failure.
2. There are unusual features of a particular model of device or component.
3. Causes of failure can be eliminated.

I. A program should be established to notify the water user when his backflow preventer must be tested. (A minimum of once each year is required.) After installation or repair, a backflow preventer should be tested and approved before it is accepted.

V. CAUSES OF BACKFLOW

A "cross-connection" as defined in this manual is:

> "Any unprotected connection between any part of a water system used, or intended, to supply water for drinking purposes and any source or systems containing water or a substance that is not, or cannot be, approved as safe, wholesome, and potable for human consumption."

Backflow can occur through a cross-connection either by "back-siphonage" or "back pressure."

A. *Backflow Caused by Back-Siphonage*

Back-siphonage is backflow caused by negative or reduced pressure in the supply piping. The principal causes of back-siphonage are:

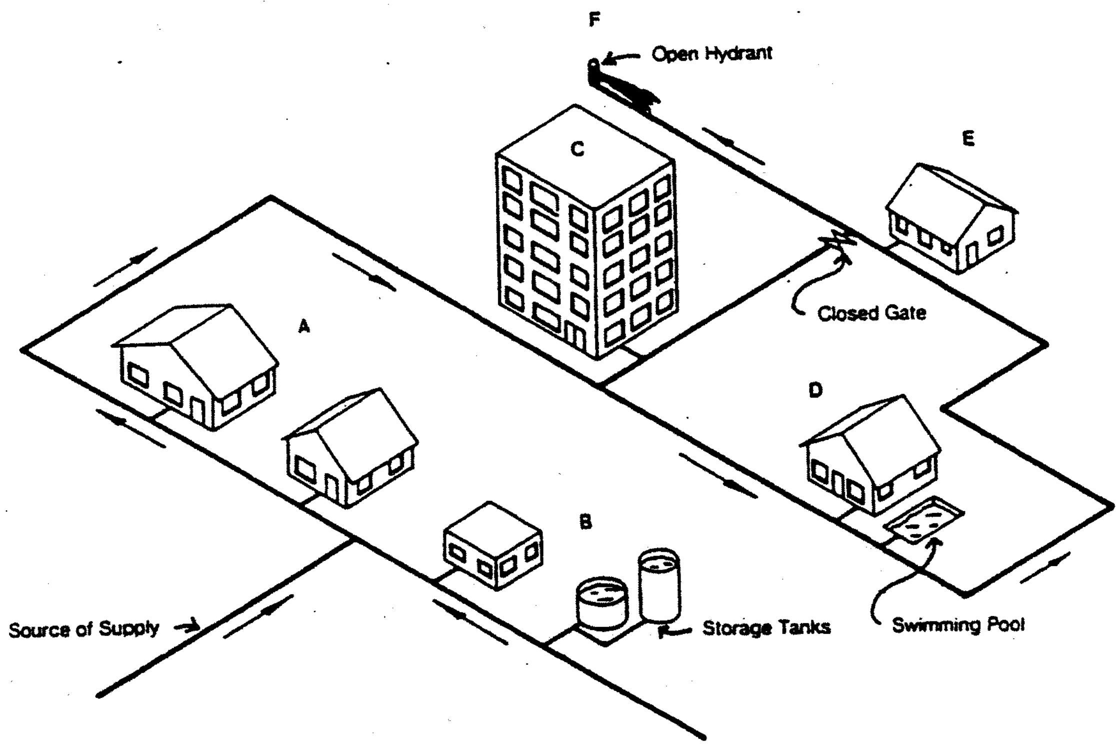
1. Undersized supply piping;
2. Waterline repairs or breaks at a location lower than a water service point;
3. Reduced water system pressure caused by high water use, such as fire fighting or water main flushing; or
4. Reduced water system pressure on the suction side of an on-line booster pump.

Example of Back-Siphonage Due to High Withdrawal of Water: The illustration on page V-2 shows how main pressure can be reduced due to high withdrawal of water causing a backflow condition. Under normal flow conditions (dotted line on graph), the distribution pressure varies from 100 psi where it enters the grid to 50 psi at the hydrant on the far side of the grid. (NOTE: Under normal flow conditions, all premises being served fall below the dotted line.) Assume the hydrant at point F is opened and the valve at point E has been accidentally left closed. The supply of water to the hydrant during high demand (solid line on graph) has been restricted due to a closed valve at point E; therefore, when the hydrant is opened, the pressure at that point drops to zero. Now the storage tank at point B, the top floors of the tall building at point C, the house and the swimming pool at point D, and the house at point E all fall about the high demand line.

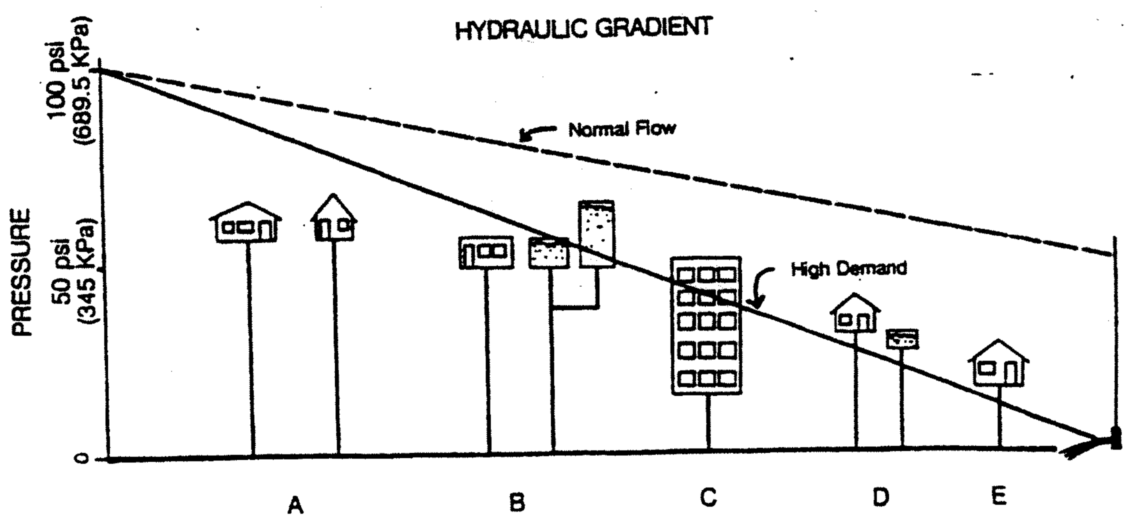
The pressure in the main has now been reduced to a point where it is lower than those areas that fall above the line. Therefore, the water will tend to run toward the lower pressure causing a potentially serious backflow condition.

The above backflow condition can be aggravated by the addition of booster pumps either on the fire truck or within a building's fire system.

BACK-SIPHONAGE DUE TO
HIGH WITHDRAWAL OF WATER



HYDRAULIC GRADIENT



07774

085371

B. *Backflow Caused by Back Pressure*

Backflow caused by back pressure occurs when the user system is at a higher pressure than the public water system. Major sources of back pressure are:

1. Booster pumps supplying water to industrial fluid piping systems;

2. Potable water system connections to pressurized industrial fluid systems, such as boilers;

3. Interconnection with other piping systems operating at higher pressures; and

4. Booster pumps in high-rise buildings or other premises to provide water for fire protection.

Example of Backflow Due to Back Pressure: The illustration on page V-4 shows how pumps on the customer's water system can increase the pressure to a point where it exceeds the public water system pressure, causing a backflow condition. This example illustrates the common practice of flushing ship fire-fighting systems by connecting to dockside freshwater supplies. As shown on the graph, under normal conditions the pressure in the main is 100 psi, and approximately 75 psi where it enters the ship's system.

After completing the flushing operation, a test is conducted to determine if the fire pumps aboard ship are operating properly. As shown on the graph, the fire system pressure is boosted to 200 pounds. If the valve at point A is accidentally left open, the fire system pressure is transferred through the freshwater supply to the city main at which point the pressure is 150 psi. Now, with the customer's water pressure higher than the public water system pressure, dockside water is forced into the public water supply.

VI. BACKFLOW PREVENTERS

A. *Approval of Backflow Preventers*

Only backflow preventers that have passed both laboratory and field evaluations by a recognized testing agency and accepted by both the water supplier and the health agency should be used.

B. *Installation Requirements*

1. *Air-Gap Separation (AG):* The air-gap separation should be located on the water user's side of and as close to the user connection as is practicable. *All piping from the user connection to the receiving tank shall be above grade and entirely visible unless water supplier and health agency approves the burial of the line.* Water take-offs between the user connection and the air-gap separation shall be protected in a manner approved by the health agency and water supplier. See illustration on page VI-2.

2. *Reduced Pressure Principle Device (RP):* The approved reduced pressure principle device should be installed on the user's side of and as close to the user connection as is practicable. The device should be installed not less than 12 inches above grade and shall be readily accessible for maintenance and testing. Water take-offs between the user connection and the RP should be protected in a manner approved by the health agency and water supplier. See illustration on page VI-3.

3. *Double Check Valve (DC):* The double check valve should be located on the user's side of and as close to the user connection as is practicable. The double check valve should be preferably above grade readily accessible for maintenance and testing. Water supplied from any point between the user connection and the DC should be protected in a manner approved by the health agency and water supplier. See illustration on page VI-4.

4. *Pressure Vacuum Breaker (PVB):* The pressure vacuum breaker should be located such that the critical level (C-L) is: (a) at least 12 inches above the highest point reached by any water beyond the device, and (b) not less than 12 inches above the surrounding grade or floor. The PVB shall be readily accessible for maintenance and testing. The PVB shall not be subjected to back-pressure. Only industrial (nonpotable) fluid may be supplied from beyond the PVB. (Refer to Glossary for definition of "critical level.") See illustrations on pages VI-5 and VI-6.

5. *Atmospheric (Nonpressure) Vacuum Breaker (AVB):* The atmospheric (nonpressure) vacuum breaker should be located such that the critical level (C-L) is at least six inches above the highest elevation of the piping system beyond the AVB. Fixtures with integral vacuum breakers manufactured and approved as a unit may be installed in accordance with their approval requirements. At no time should an AVB be subjected to back pressure. See illustrations on pages VI-5 and VI-7.

TANK SHOULD BE OF SUBSTANTIAL CONSTRUCTION AND OF A KIND AND SIZE TO SUIT CONSUMER'S NEEDS. TANK MAY BE SITUATED AT GROUND LEVEL (WITH A PUMP TO PROVIDE ADEQUATE PRESSURE HEAD) OR BE ELEVATED ABOVE THE GROUND.

C. *Testing and Maintenance*

1. Water users are responsible for inspecting backflow preventers as required by the health agency and/or water supplier. Backflow preventers should be tested only by certified backflow preventer testers.

2. Backflow preventers should be tested immediately upon installation and at least once each year the preventer continues in service unless more frequent testing is required. Reports on testing and maintenance of backflow preventers should be filed with the health agency and/or water supplier.

   a. Relocation: If an approved backflow preventer is relocated, it should be tested before it is returned to service.

   b. Repiping: If the supply line is changed, the backflow preventer should be tested before it is returned to service.

   c. Repair or Overhaul: If a backflow preventer is repaired, it should be tested before it is returned to service. In addition, the health agency and/or water supplier may require more frequent testing. (NOTE: Cleaning is a repair.)

3. Backflow preventers that were installed before a formal program was inaugurated or have a record of failure should be tested more frequently as determined by the water supplier and/or health agency.

4. All tests, repairs, overhauls, and/or replacements should be the expense of the water user.

D. *Backflow Preventer Removal*

Health agency and/or water supplier approval must be obtained before a backflow preventer is removed, relocated, or replaced.

1. All replacement backflow preventers must be approved as required in VI—Approval of Backflow Preventers, paragraph A, and must be commensurate with the degree of hazard involved.

2. Relocation: A backflow preventer may be relocated following confirmation by the health agency or water supplier that the relocation will continue to provide the required protection and satisfy installation requirements. (A retest is required.)

E. ***Records***

Where testing of devices is the responsibility of the water user, the water supplier or the health agency should notify the water user when routine testing of backflow preventers is needed and of the date by which the test must be completed. The water user should supply a copy of the test report to the water supplier and/or the health agency. Failure to supply needed copies of the test report to the water supplier or health agency could result in enforcement actions by the water supplier and/or health agency including cutoff of water service.

VII. BACKFLOW PREVENTION PROCEDURES

A. *Assessment of Hazard*

Section III, Where Protection Is Required, discusses the protection of the public water supply at the user connection and the people inside a premises. Premises isolation should be provided where internal protection will not protect the public water supply. Internal protection, however, can in some situations eliminate the hazard or protect the people inside the premises. To select a particular means or mechanical device to prevent backflow, an assessment should be made of:

1. The degree of hazard
2. The probability of a backflow occurring (factors causing the backflow)
3. Complexity of piping and probability of modification

Three degrees of hazard are considered: severe, moderate, and minor. These degrees of hazard are defined as follows:

1. *Severe:* A cross-connection or potential cross-connection involving any water or substance capable of causing death, or spreading disease and/or illness.
2. *Moderate:* An existing cross-connection or a high probability of a cross-connection being made between the domestic water piping and any pipe, vat, or tank intended for carrying or holding potable water which has a probability of becoming contaminated with any substance.
3. *Minor:* A cross-connection or potential cross-connection involving any substance which has a low probability of becoming a moderate hazard and would be aesthetically objectionable if introduced into the domestic water supply.

Because of the variable factors of hazard, probability, and extent, it is not possible to prescribe specific means of preventing backflow in all situations except for a limited number of situations discussed elsewhere in this manual. In other situations, only recommendations are made, and *persons responsible for selection of the protective measures should carefully assess the specific situation where protection is necessary.*

B. *Procedure for Protection of Potable Water Systems Within User Premises*

Protection of potable water systems within water user premises shall include, but not be limited to, the following (see illustrations on pages VII-3, 4, 5, 6, and 7):

1. *Plumbing:* Plumbing shall comply with the local plumbing code requirements.

2. *Separate Drinking Water Systems:* Whenever the health agency or water supplier determines that it is not practical to internally protect a user's water system, a separate approved potable water supply shall be provided for the on-premises users.

3. *Industrial Lines:* Industrial lines shall supply water for industrial processes or operation.

4. *Sewage Treatment Plants and Pumping Stations:* Potable water pipelines shall not be connected to sewage pumps or pipelines. Other piping, equipment, or tanks in sewage treatment plants or sewage pumping stations may be supplied only from industrial lines.

5. *Pier and Dock Hydrants:* Backflow protection shall be provided on each potable water pier head outlet used for supplying vessels at piers, docks, marinas, or waterfronts. This protection must be located where it will prevent the backflow of any water from the vessel into the potable water pipeline or into another vessel.

C. *Procedures for Premises Isolation*

The following backflow preventers are acceptable for premises isolation:

1. Air-Gap Separation (AG)

2. Reduced Pressure Principle Device (RP)

3. Double Check Valve (DC)

Cross-connection control experience has provided adequate information to establish a list of those premises where hazardous cross-connections continuously occur or where the potential hazard is so great that these premises should be separated from the public water system. The State of California, Department of Health Services, has established mandatory protection for some of these premises (see Cross-Connection Regulations, Title 17, California Administrative Code, Sections 7603 and 7604). However, it is essential that each premises be examined individually to determine the type of backflow preventer that will be required.

The following list indicates some facilities usually requiring premises isolation:

1. Sewage treatment plants; pumping stations.

2. Reclaimed waste-water areas.

3. Hospitals; clinics.

4. Laboratories.

5. Chemical plants using a water process.

6. Radioactive material processing plant.

7. Petroleum processing or storage plants.

8. Metal plating industries.

9. Piers and docks.

10. Unapproved auxiliary supply.

11. Premises where inspection is restricted.

12. Other areas specified by the enforcement agency.

VIII. RECOMMENDED BACKFLOW PREVENTER INSTALLATION PRACTICES

A. *Waste-Water and Toxic Chemicals*

An AG or RP should be provided at services to sewage treatment plants, sewage pumping stations, reclaimed water reuse areas, and areas where toxic substances in toxic concentrations are handled under pressure. Under no circumstances should there be any connection between the potable supply and piping containing liquids that may cause a severe health hazard (see page VII-2). Sewage treatment plants, reclaimed water use areas, and areas where toxic chemicals are handled under pressure should be protected by premises isolation and internal protection.

The degree of treatment of the reclaimed water is not a factor in determining the protection necessary since during periods of failure even tertiary treated waste-water is a potential health hazard.

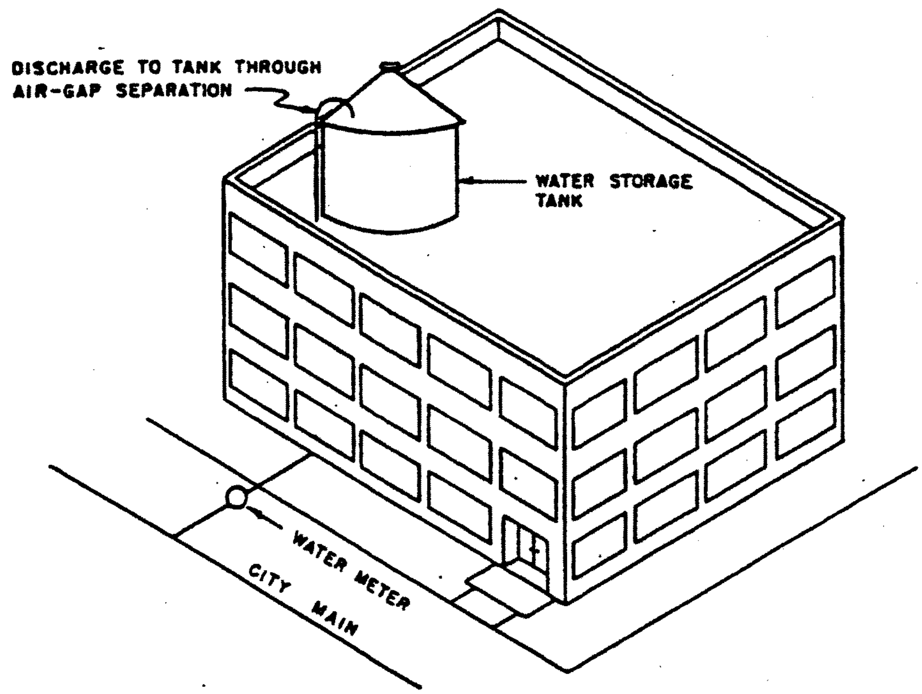
Where there are individual sewage pumping plants on the property, the service should be protected by an approved double check valve assembly and the water service in the area of the sewage pump should be protected by a RP.

B. *Auxiliary Water Systems*

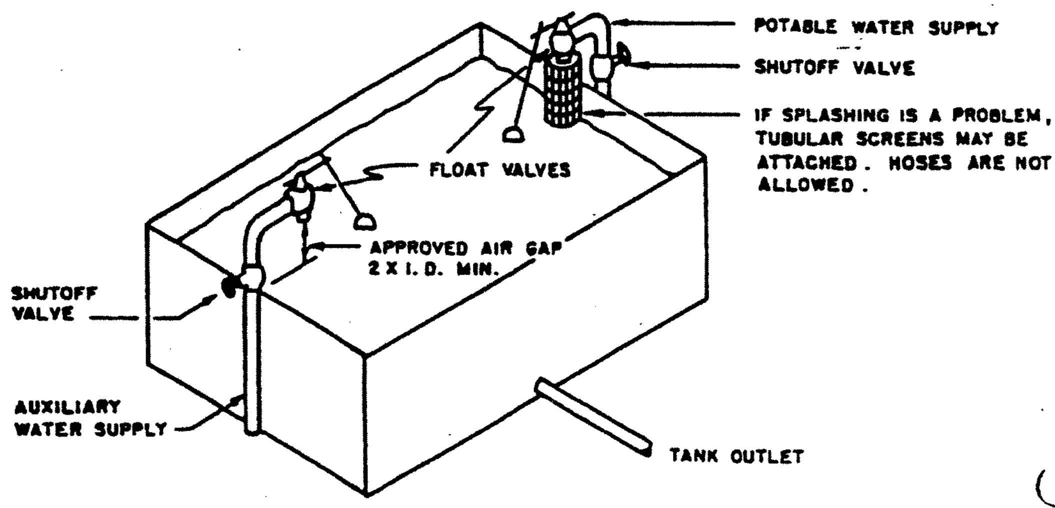
An backflow preventer should be installed at the service connection to any premises where there is an unapproved auxiliary water supply or system, even though there is no connection or cross-connection. This should be accomplished in the following manner:

1. An AG or a RP should be provided at the user connection when the auxiliary water supply is, or may be, contaminated. See illustration on page VIII-2.
2. A DC should be provided at the user connection when a moderate hazard exists in the area served or where internal protection adequately safeguards the auxiliary supply.
3. No backflow protection at the user connection is necessary if the auxiliary water system holds a valid water supply permit issued by the state or local health department and if the water supplier accepts the auxiliary source as an additional supply.

LARGE BUILDING WITH AIR GAP
AT WATER STORAGE TANK



AIR GAP AT MAKEUP TANK FOR
AN AUXILIARY WATER SYSTEM



07794

085391

C. *Irrigation Systems*

Atmospheric and pressure vacuum breakers are preferred for backflow protection on irrigation systems. These devices, however, are not adequate protection in areas where they are subject to back pressure. In the situation where there is a possibility of back pressure, a RP is required.

A RP or AG should be used in all cases where fertilizer, herbicides, or pesticides are injected into the sprinkler system.

The following are examples of:

1. *Hillside Irrigation with Water Service at Bottom*

    a. Atmospheric Vacuum Breaker: Note there are no control valves downstream from the vacuum breaker (see illustration on page VIII-5).

    b. Pressure Vacuum Breaker: Note the control valves may be located anywhere in the system (see illustration on page VIII-5).

    c. Reduced Pressure Principle Device: Note the control valves may be located anywhere in the system. Also, the fertilizer injector pump may be included in this system (see illustration on page VIII-6).

2. *Level Terrain—Multizone Irrigation System*

    a. Atmospheric Vacuum Breaker: Installed downstream of last control valve (see illustration on page VIII-7).

    b. Pressure Vacuum Breaker: No restriction on control valve location (see illustration on page VIII-7).

    c. Reduced Pressure Principle Device: May also be installed on these systems if required (see illustration on page VIII-8).

D. *Fire Systems*

A fire-fighting system with a direct connection to the public potable water system should be protected in a manner commensurate with the hazard. Fire protection systems may be classified as follows:

1. Class I

   Direct connections from domestic water mains only; no pumps or reservoir; no physical connection from other water supplies; no anti-freeze or other additives of any kind; and all sprinkler drains discharging to atmosphere, dry wells, or other safe outlets.

2. Class II

   Same as Class I, except that booster pumps may be installed in the connections from the street mains. (Booster pumps do not affect the potability of the water supply. It is necessary, however, to avoid drafting so much water that pressure in the water main is reduced below 10 psi.)

3. Class III

   Direct connection from public water supply main plus one or more of the following: elevated storage tanks; fire pumps taking suction from above-ground covered reservoirs or tanks; or pressure tanks. All storage facilities are filled or connected to public water only; the water in the tanks to be maintained in a potable condition.

4. Class IV

   Directly supplied from public mains similar to Classes I and II, connection for fire pumper truck or with an auxiliary water supply on or available to the premises.

5. Class V

   Directly supplied from public mains and interconnected with auxiliary supplies, such as: pumps taking suction from reservoirs exposed to contamination or from rivers and ponds; driven wells; mills or other industrial water systems; or systems where antifreeze or other additives are used.

6. Class VI

   Combined industrial and fire protection systems supplied from the public water mains only, with or without gravity storage or pump suction tanks.

Generally, fire protection systems of Classes I and II will not require backflow protection at the service connection.

Class III systems should be provided with minimum protection (approved double check valves) to prevent contaminated waters from backflowing into the public potable water system.

Class IV systems should be provided with a minimum of a DC at the service connection. An AG or RP may be required depending on the quality of the auxiliary supply.

Class V systems should be provided with maximum protection (AG or RP) to protect the public potable water system.

Class VI system protection depends on the requirements of both industry and fire protection and could only be determined by a survey of the premises.

A meter (compound, detector check) should not be permitted as part of a backflow protection device. An exception may be made, however, if the meter and backflow preventer are specifically designed and approved for that purpose.

E. *Dockside Watering Points and Marine Facilities*

The actual or potential hazard to any water supply system by any marine facility or dockside watering point must be evaluated on a case-by-case basis. The basic risk is that fire pumps or other pumps aboard ship could pump contaminated water back into the water supply system where it could affect other ships or other facilities located in the area. The contaminated water can also be pumped back into a public water system without adequate backflow protection. The same risk occurs in areas where dockside watering facilities are used in connection with marine construction, maintenance or repair, and permanent or semi-permanent moorages.

Minimum system protection for marine installations may be accomplished in one of the following ways:

1. Water connections directly to vessels for any purpose must have a RP installed at the pier hydrants. All hydrants in the dockside area used or available for use in providing water to vessels should be so protected. The entire dockside area should also be isolated from the water supplier's system by an AG (see illustration on page VII-5).

2. At the user connection, water delivered to marine facilities for fire protection only, where no auxiliary supply is being used and there are hydrants available for connection to a vessel's fire system, should have a RP installed at the user connection.

3. Water delivered to a marine repair facility should have a RP installed at the user connection.

4. Water delivered to small boat moorages that maintain hose bibbs on a dock or float should have a RP installed at the user connection and a VB on all hose bibbs. If a sewage pump station is provided, the area should be isolated by installation of an RP.

F. *Portable Spray and Cleaning Equipment*

All portable pressure spray or cleaning units that have the capability of connecting to any water supplier's system should be provided with an AG installation or a RP (see illustration on page VIII-12).

G. *Cross-Connection Through Air Valves*

The term "air valve" generally refers to three types of valves: air and vacuum valves, air release and combination air release valves, and vacuum valves.

The air and vacuum valve is used to automatically allow air to enter a pipe when the pipe is drained. Allowing air to enter a thin-walled pipe prevents collapse of the pipe due to a vacuum created by draining the pipe and helps to prevent a back-siphonage condition in services.

The air release valve is used to release the small amount of air that accumulates at high points in a pipeline that restricts the flow capacity of the pipe.

All air valves should be installed so as not to create a cross-connection. The valve should be installed above ground or be properly vented.

H. *Miscellaneous Uses of Water From Fire Hydrants*

A number of water suppliers allow the use of water directly from fire hydrants for flushing storm and sanitary sewers and similar uses. Where this is permitted, it is essential that a portable RP be provided to protect the water supplier's system.

IX. CERTIFICATION OF BACKFLOW PREVENTER TESTERS

In some areas, persons inspecting or testing backflow preventers are certified as backflow preventer testers by the health agency or the water supplier. This section outlines recommended features of a certification program for backflow preventer testers.

A. *Application*

Persons desiring to qualify to inspect or test backflow preventers should apply to the health agency or water supplier for certification as a backflow preventer tester.

B. *Qualifications*

The health agency and/or water supplier should evaluate the applicant's training and experience and should conduct the necessary written and performance examinations.

C. *Certification*

Upon meeting all of the requirements for certification, the health agency or water supplier should certify the applicant as a backflow preventer tester.

NOTE: A tester may be certified to test all types of backflow preventers or be restricted to certain devices or installations as determined by the health agency.

Some examples of certification are as follows:

1. *General*: A General certificate permits the tester to examine any reduced pressure principle backflow preventer, double check valve, or pressure vacuum breaker and complete and file the appropriate record.

2. *Limited:* A Limited certificate permits the tester to examine a specific type(s) of device(s) owned and operated by the tester's employer and complete and file the appropriate record.

D. *Revocation*

Certification should be rescinded immediately if a tester: (1) fails to comply with the provisions of the Cross-Connection Regulations or other rules and regulations associated with backflow protection, or (2) falsifies backflow preventer tests or reports.

X. MARKING SAFE AND UNSAFE WATER LINES AND OUTLETS

A. *Marking Safe and Unsafe Water Lines*

When premises contain dual or multiple water systems and piping, all portions of these pipelines should be painted, banded, and/or marked at sufficient intervals to clearly differentiate potable water lines from nonpotable or industrial water lines. All outlets from secondary or other potentially contaminated water systems should be posted as unsafe for drinking.

B. *Methods of Line Identification*

Identification of water lines should be as follows:

1. (a) Complete color painting of all visible parts of the pipe, or

   (b) Color band a minimum of ten inches in width, located at least every twenty-five feet of line length and on each side where a pipe passes through a wall. (This requirement concurs with the recommendations of the American Standards Association and does not conflict with either Title 17 or Title 8 of the California Administrative Code.)

and

2. (a) The type of water being transported should be lettered or stenciled on the piping adjacent to each band [refer to 1 (b) above] or at least every twenty-five feet and on each side where a pipe passes through a wall if all visible parts of the pipe are painted [refer to 1 (a) above]. The letter size and the color of the letters, and the letter background, should be such as to be immediately legible.

or

   (b) A subcolor band two inches in width identifying the type of water when applied at a visible edge of the ten-inch band described in 1 (b) above or every twenty-five feet and on each side where a pipe passes through a wall as described in 1 (a) above.

3. The names and subbanding should be maintained legible.

4. A placard identifying the color code/labeling designation should be posted at sufficient locations to allow ready identification of potable water lines.

C. *Method of Outlet Identification*

When it is necessary to identify an outlet as unsafe for drinking, the identification shall be as follows:

1. The outlet should be tagged or labeled with metal or other suitable material with applicable wording as follows:

   "DANGER—UNSAFE WATER"

   These should be securely fastened at or to each respective outlet.

2. The tag or label should be affixed in such a manner as to be immediately identifiable to the outlet user.

3. The tag or label letter size, color, and background should be such as to be easily legible.

4. The tag or label should be maintained legible.

XI. ADMINISTRATIVE PROCEDURES

A. *Water Use Survey*

1. Priority of Survey

   Water use surveys should generally be performed according to the following priorities:

   a. Review application for new service.

   b. Investigate water user premises selected depending upon the degree of hazard.

   c. Review plans as requested by building department, architect, engineer, and/or builder.

   d. Investigate existing services upon request or upon notification that a hazard may exist.

2. Initial Survey

   The initial survey should consist of a thorough investigation of all water uses and piping systems, planned or existing, within a water user's premises to identify existing hazards and/or code infractions.

   NOTE: If conditions found during the initial survey show that the safety of the public water system is endangered, service may be discontinued immediately without notice.

3. Water User Notification

   Water users should be notified, in writing, of survey findings and corrective action to be taken if required. Copies may be sent to the plumbing official. A follow-up should be made to verify correction.

   a. If there is evidence that corrective action has not been taken, a second notice should be sent to the water user.

   b. If the water user fails to respond to the second notice to correct violations, the water user and designated representative should be notified by certified mail to appear for an office hearing to show cause for noncompliance. The request shall establish a specific date, time, and place for the office hearing.

   c. The water supply to the premises may be discontinued if:

      (1) The office hearing does not provide evidence that corrective action is being taken, or

      (2) The water user does not appear for the office hearing.

4. Reinspection

   A reinspection will be made at the request of the water user to verify corrective action.

B. *Backflow Preventer Testing Program*

The program of testing backflow preventers should include:

1. Inspecting all backflow preventers to verify proper location, effective operation, and to obtain other pertinent information (manufacturer, size, type, model, serial number, ownership, etc.).

2. Maintaining a record of backflow preventers in use.

3. Maintaining a testing program for all backflow preventers in use, including:

   a. Notification of water user of responsibility to test and maintain backflow preventer, the frequency of needed test, and, if necessary, repair or replacement.

   b. Supplying necessary backflow preventer test and maintenance report forms.

C. *Additional Activities*

Persons involved in cross-connection control program should:

1. Consult with concerned parties, such as health agency, plumbing official, water suppliers, plumbers, architects, contractors, and manufacturers.

2. Coordinate with other cross-connection control programs.

3. Notify water suppliers, health agency, plumbing officials, certifying laboratories, and certified testors of consistant failures of a particular device.

4. Provide education for those involved in cross-connection control programs.

XII. WATER SHUTOFF—CAUSE AND PROCEDURE

A. *Water Shutoff Conditions*

When water uses are found that pose a clear and immediate hazard to the potable water supply and these hazards cannot be immediately abated, the shutoff procedures should be initiated. Conditions requiring water shutoff shall include, but not be limited to, the following:

1. Refusal to test backflow preventer.
2. Refusal to repair faulty backflow preventer.
3. Refusal to replace faulty backflow preventer.
4. Direct or indirect connection between a potable water system and a sewer line.
5. Unprotected direct or indirect connection between a potable water system and a system or equipment containing toxic chemicals or sewage.
6. Unprotected direct or indirect connection between potable water systems and auxiliary water systems.
7. Unprotected direct connection between potable water system and nonpotable or nonpressure system.
8. Refusal to correct violations.

B. *Water Shutoff Procedure*

When it becomes necessary to shutoff a user's water, the following steps should be followed:

1. A reasonable effort should be made to advise consumer of intent to institute water shutoff.
2. The health agency should be advised, if necessary, of pending water shutoff.

NOTE: Water supply is to remain inactive until correction of violations has been approved.

GLOSSARY

AIR-GAP SEPARATION (AG)—A physical break where a pipe or hose is connected to or discharges into a vessel or conduit, provided that the break is at least double the diameter of the pipe, measured vertically above the rim of the receiving vessel or conduit and in no case less than one inch.

APPROVED BACKFLOW PREVENTER—A backflow preventer approved or acceptable to the water supplier and the health agency.

ATMOSPHERIC VACUUM BREAKER (AVB)—A vacuum breaker designed and used so as not to be subject to continuous static line pressure.

AUTOMATIC FIRE-EXTINGUISHING SYSTEM—A fire suppression system that is designed to automatically activate in case of fire.

BACKFLOW—The undersirable flow of water or other liquids, gases, mixtures, or substances into the distribution system.

BACKFLOW PREVENTER—An effective device, means, method, or construction used to prevent backflow into a potable water system.

CONTAMINATION—An impairment of the potable water supply by any foreign substance.

CRITICAL LEVEL (C-L)—The marking on a backflow preventer at a point which determines the minimum elevation above the flood level rim of the fixture or receptacle served at which the device may be installed. When a backflow preventer does not bear a critical level marking, the bottom of the device shall constitute the critical level.

CROSS-CONNECTION—Any unprotected connection between any part of a water system used, or intended, to supply water for drinking purposes and any source or system containing water or substance that is not or cannot be approved as safe, wholesome, and potable for human consumption.

DISTRIBUTION SYSTEM—All facilities used by a water supplier to deliver water from the source or related treatment facilities to the user connections.

DOUBLE CHECK VALVE (DC)—A backflow preventer consisting of an assembly of at least two independently acting approved check valves, including tightly closing shutoff valves on each side of the check valve assembly and connections available for testing the water-tightness of each check valve.

HEALTH AGENCY—The health authority (state, county, or local) having jurisdiction.

INDUSTRIAL FLUID—Any fluid or solution which could create a contamination if introduced into a potable water system.

INDUSTRIAL LINE—A separate water piping system serving water-using devices, with a suitable backflow preventer on this line at the point of takeoff from a potable water line.

INTERNAL PROTECTION—Preventing backflow into a potable water system by creating industrial lines within a water user's system or by eliminating cross-connections by requiring or by installation of protective devices on potential sources of contamination.

PLUMBING OFFICIAL—The individual official, board, department, agency, commission, etc., established and authorized by law to administer and enforce plumbing code requirements.

POTABLE WATER—Water that is suitable, safe, or prepared for drinking.

PREMISES ISOLATION—Preventing backflow into a public water system from a user's premises by installing a suitable backflow preventer at the user connection.

PRESSURE VACUUM BREAKER (PVB)—A vacuum breaker designed to operate under conditions of static line pressure.

PUBLIC WATER SYSTEM—A system, regardless of type of ownership, for the provision of piped water to the public for domestic use, if such system has at least 5 service connections or regularly serves an average of at least 25 individuals daily at least 60 days out of the year.

RECLAIMED WATER—Water which, as a result of treatment of waste-water, is suitable for a direct beneficial use or a controlled use that would not otherwise occur.

REDUCED PRESSURE PRINCIPLE DEVICE (RP)—A backflow preventer that:

a. Incorporates two or more internally loaded check valves, an automatically operating differential relief valve located between the two check valves, two shut-off valves, and necessary appurtenances for testing.

b. Maintains pressure in the zone between the two check valves less than the pressure on the public water system side of the device.

c. Maintains the reduced pressure between the check valves in case of leakage of either check valve by discharging to the atmosphere.

d. Opens the relief valve to atmosphere to provide an air-gap separation in the backflow preventer when the inlet pressure is two pounds per square inch or less.

SERVICE CONNECTION—A connection between water supplier main and a user connection.

UNPROTECTED—When used in reference to connection between piping systems means that a suitable backflow preventer is not installed on the connection.

USER CONNECTION—The point of connection of a user's piping to the water supplier's facilities.

WATER SUPPLIER—A person who owns or operates a public water system.

WATER USER—Any person obtaining water from a water supplier.

APPENDIX A

BACKFLOW PREVENTION DEVICE FIELD TEST PROCEDURES

For Reduced Pressure Principle Devices

Equipment required:

1—Differential Pressure Gage — 0-15 psid (0.1 or 0.2 psi graduations)

NOTE: There are now three such gages on the market. They are manufactured by Midwest Instrument Co., ITT Barton, and Charles Meriam Co.

3—6 ft. lengths — ¼" I.D. high pressure hose with screw type ¼" couplings. (Midwest comes equipped with hose)

6—¼" IPS to hose adapter fittings
(Victor 50-20 or equivalent for Barton and Meriam)
(Weatherhead 44 for Midwest)

3 each adapter fittings for the range of devices — brass 1/8 x 1/4, 1/4 x 1/2, and 1/4 x 3/4

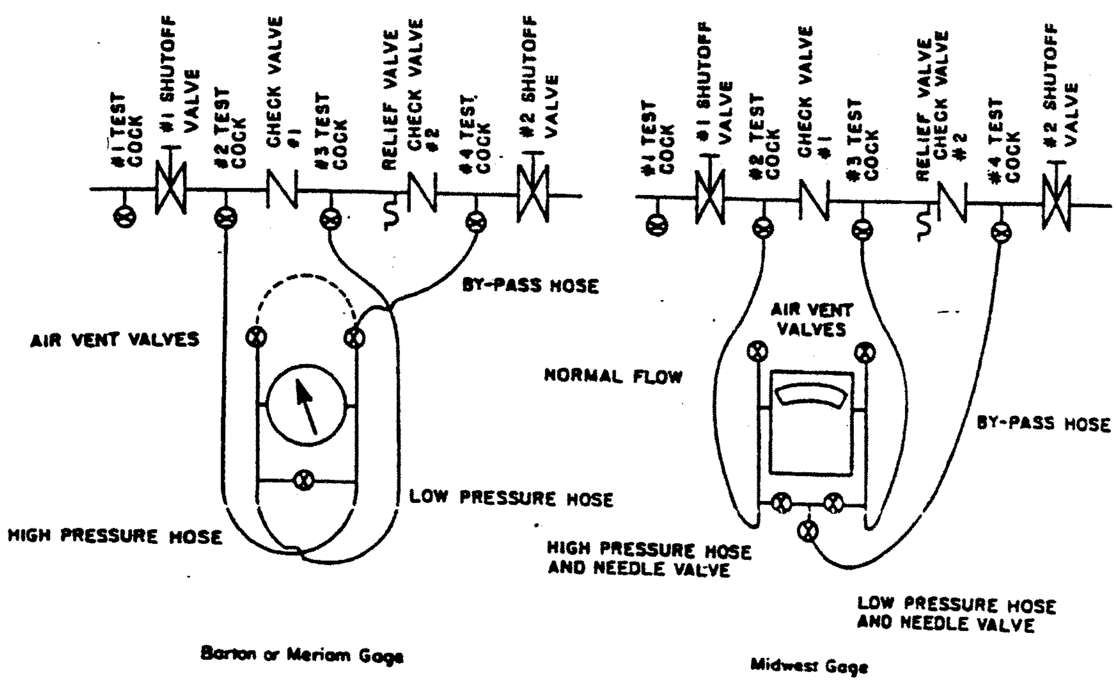

FIGURE A—1
TEST EQUIPMENT FOR REDUCED PRESSURE PRINCIPLE DEVICES

07813

085410

Field Test Procedure

TEST NO. 1

Purpose: To test the operation of the pressure differential relief valve.

Requirement: The pressure differential relief valve must operate to maintain the "zone" between the two check valves at least 2 psi less than the supply pressure.

Steps:

a. Install hose from the No. 2 test cock to the high pressure side of the differential pressure gage.

b. Install hose from the No. 3 test cock to the low pressure side of the differential pressure gage.

c. Open test cocks No. 2 and No. 3 and vent all air from the hose and gage.

d. Close No. 2 shutoff valve.

e. Observe, but do not record, the apparent pressure drop across the No. 1 check valve; during all all subsequent steps and "test" of this procedure, the differential pressure gage is "on line" showing the actual pressure drop across the No. 1 check valve.

f. For the Barton or the Meriam gage:

   1. Install a by-pass hose from the high side needle valve to the low side needle valve and vent all air before the final installation.

   2. Open the high side needle valve, then crack the low side needle valve to by-pass water from No. 2 test cock to No. 3 test cock.

   3. Watch the pressure differential drop *slowly* to relief valve opening point—record this value.

   4. Close needle valves and remove the by-pass hose.

   For the Midwest gage:

   1. With the vent hose unattached and the vent needle valve closed, open the high side needle valve and crack the low side needle valve to by-pass water from the No. 2 test cock to the No. 3 test cock.

   2. Watch the pressure differential drop *slowly* to the relief valve opening point—record this value.

   3. Close the needle valves.

TEST NO. 2

Purpose: To test the No. 2 check valve for tightness against reverse flow.

Requirement: The No. 2 check valve shall be tight against reverse flow under all pressure differentials.

Steps:

a. Maintain the No. 2 shutoff valve in a closed position (from Test No. 1).

b. Bleed a small amount of water from the "zone" by means of either the vent needle valve on the gage or through test cock No. 4 in order to reestablish the normal reduced pressure within the "zone."

c. For the Barton or Meriam Gage

   1. Install the by-pass hose from the high side needle valve to the No. 4 test cock—vent all air before final installation.

   2. Open No. 4 test cock and the high side needle valve.

   3. If the indicated differential pressure remains steady, then the No. 2 check valve is reported as "closed tight." If the pressure differential falls, then the check valve is noted as "leaking."

d. For the Midwest gage:

   1. Install the vent hose from the gage manifold to the No. 4 test cock—venting all of the air before final installation.

   2. Open No. 4 test cock and both the "high" and the "vent" needle valves.

   3. If the indicated pressure differential remains steady, then the No. 2 check valve is reported as "closed tight." If the pressure differential falls, then the check valve is noted as "leaking."

TEST NO. 3

Purpose: To determine the static pressure drop across check valve No. 1.

Requirements: The static pressure drop across check valve No. 1 shall be at least 3.0 psi greater than the pressure differential between the line pressure and the pressure in the "zone" required to open the pressure differential relief valve.

Steps:

a. With the by-pass hose connected to test cock No. 4 as in Step c or d of Test No. 2 (above), the steady state indicated pressure differential (not falling) is the actual static pressure drop across check valve No. 1 and is to be recorded as such.

b. Close all test cocks, open shutoff valve No. 2, and remove all test equipment.

Instructions for a Leaking No. 2 Shutoff Valve

In tests No. 2 and No. 3, above, the size of the by-pass hose determines the capability of this test procedure to cope with a leaking No. 2 shutoff valve. As long as the hose capacity is enough to satisfy the leak of the No. 2 shutoff valve, then the above procedure will provide valid data regarding the tightness of the No. 2 check valve and also the true pressure differential across the No. 1 check valve. If the volume of the leak of the No. 2 shutoff valve exceeds the capacity of the gage hose, then a tee may be placed in the No. 4 test cock to accommodate an additional by-pass hose from the No. 1 test cock to the No. 4 test cock.

For Double Check Valve Assemblies

A pair of calibrated bourdon tube gages or a calibrated duplex gage can also be used for field testing a double check valve assembly. The equipment needed is as follows:

a. Bourdon tube gages or duplex gage with 1 or 2 psi increments and with a range of twice the expected maximum water line pressure.

b. Needle valves and fittings as indicated in the sketch.

c. Three lengths, approximately 5 feet each, of high pressure ¼ inch hose.

d. Six Victor 50-20 fittings or equivalent.

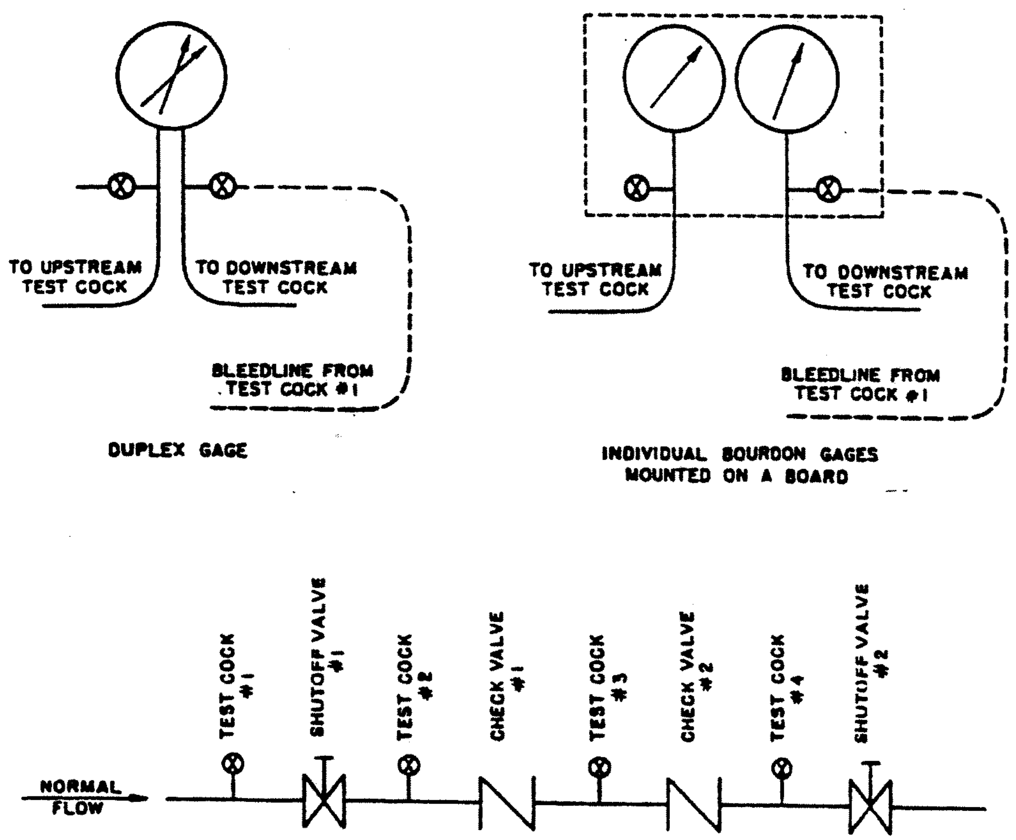

FIGURE A–2
TEST EQUIPMENT FOR DOUBLE CHECK VALVE ASSEMBLIES

Field Test Procedure

TEST NO. 1 (See Figure A–2)

Purpose: To test No. 1 check valve for tightness against reverse flow.

Requirement: The valve shall be tight against reverse flow under all pressure differentials.

Steps:

a. Connect one gage hose to test cock No. 2 and connect the other gage hose to test cock No. 3.

b. Open test cocks and vent hoses.

c. Close No. 2 shutoff valve; then close No. 1 shutoff valve.

d. By means of the needle valve, lower the pressure at test cock No. 2 about 2 psi below the pressure at test cock No. 3. If this small difference can be maintained, then check valve No. 1 is reported as "tight" or "OK." If this small difference cannot be maintained, proceed to the confirm test–Step e., etc.

e. Open shutoff valve No. 1 to repressurize the device.

f. Attach a bleed hose from test cock No. 1 to the needle valve of test cock No. 3 and vent the hose.

g. Close No. 1 shutoff valve.

h. Before tightening the bleed hose, use the needle valve on test cock No. 3 to lower the pressure in the device about 10 psi below normal line conditions; then tighten the bleed hose.

i. Simultaneously open both needle valves very slowly. If the gage shows that a greater pressure differential is created, then the check valve is reported as "tight" or "OK." If a pressure differential is not maintained, then the check valve is reported as "leaking" and the amount of leakage is visible as the discharge from the upstream needle valve.

j. Close all test cocks, remove all equipment, and reopen No. 1 shutoff valve.

TEST NO. 2

Purpose: To test No. 2 check valve for tightness against reverse flow.

Requirement: The valve shall be tight against reverse flow under all pressure differentials.

Steps: Exactly the same as in Test No. 1 except that the upstream hose is connected to test cock No. 3 and the downstream hose is connected to test cock No. 4. The bleed hose is again connected to test cock No. 1.

a. Return device to normal operating condition.

For Pressure Vacuum Breaker Assemblies

NOTE: This procedure is for the new design of loaded air relief valve pressure vacuum breakers.

Equipment required:

1–Differential pressure gage – 0-15 psid (see "Note" in Section: *For Reduced Pressure Principle Devices*)
1–Length of 1/4 inch hose with screw type couplings
1–Adapter fitting – 1/4 inch IPS x hose – brass
1–1/4" x 1/8" IPS adapter – brass

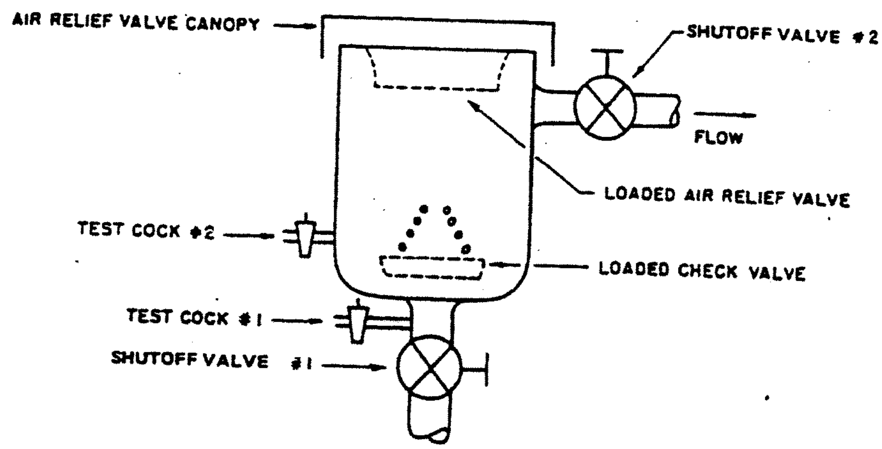

FIGURE A–3
PRESSURE VACUUM BREAKER

TEST NO. 1

Purpose: To test the opening pressure differential of the air inlet valve.

Requirement: The air inlet valve shall open when the pressure in the body is 1.0 psi above atmospheric pressure. And the air opening valve shall be fully open when the water drains from the body.

Steps:

a. Remove air opening canopy.

b. Install the high-pressure hose of the differential pressure gage to test cock No. 2 and bleed air from the hose and gage.

07819

085416

c. Close shutoff valve No. 2; then close shutoff valve No. 1.

d. Slowly open the high-pressure vent needle valve. Note and record the pressure differential at which the air inlet valve opens.

e. Close test cock No. 2 and remove equipment.

f. Open shutoff valve No. 1.

TEST NO. 2

Purpose: To test the check valve for tightness in the direction of flow.

Requirement: The check valve shall be drip-tight in the normal direction of flow when the inlet pressure is 1 psi and the outlet pressure is atmospheric.

Steps:

a. Install a transparent tube approximately 27-3/4 inches long in test cock No. 1 and fill with water.

b. Close shutoff valve No. 1.

c. Open test cocks No. 1 and No. 2. Air inlet valve will open; and, if water remains at 27-3/4 inches in the transparent tube, the check valve is reported as "tight" or "OK."

d. Close test cocks No. 1 and No. 2, remove the transparent tube, and open the shutoff valves No. 1 and No. 2.

e. Replace air opening canopy.

Alternate method using a differential gage:

Steps:

a. Attach high pressure hose of differential gage to the No. 1 test cock and vent all air from hose and gage.

b. Close shutoff valve No. 1.

c. Open test cocks No. 1 and No. 2. Air inlet valve will open; and, the differential pressure indicated by the gage will be the pressure drop across the check valve. This must be 1.0 psid or greater. Record this differential.

d. Close test cocks No. 1 and No. 2, remove gage, and open shutoff valves No. 1 and No. 2.

e. Replace air opening canopy.

APPENDIX B

AMERICAN WATER WORKS ASSOCIATION (A.W.W.A)
California-Nevada Section

RULES GOVERNING THE CERTIFICATION OF BACKFLOW PREVENTION DEVICE TESTERS

1. *General*

1.1 The purpose of these guidelines is to provide for the certification of qualified individuals for the inspection and repair of backflow prevention devices affording protection of the potable water systems as required by both federal and state statutes.

2. *Definitions*

2.1 "Approved Backflow Prevention Device" means a device that has been investigated and approved by the regulatory agency having jurisdiction.

2.2 "Approved Course of Instruction" means:

A. A course which provides a minimum of 40 hours of classroom instruction covering the theory of backflow prevention, applicable laws, the design of backflow prevention devices, the testing and maintenance of devices, and an examination; or

B. A course of instruction in a community college or the equivalent which covers the theory of backflow prevention, applicable laws, the design of backflow prevention devices, the testing and maintenance of devices, and an examination.

2.3 "Certification Administrator" or "Administrator" as used in these regulations, refers to the person employed by the Committee to administer the Backflow Prevention Device Testers Certification Program of the California-Nevada Section, A.W.W.A.

2.4 "Certified Backflow Prevention Device Tester" means a backflow prevention device tester meeting all the requirements of these guidelines and so certified by the California-Nevada Section of A.W.W.A.

2.5 "Class of Certification" shall mean that a backflow prevention device tester may be certified in one of the following categories:

A. General—Certified to test and maintain any type or manufacture of backflow prevention device.

B. Limited:

(1) Certified to test and maintain any type or manufacture of backflow prevention device within an employer's premises.

(2) Certified to test and maintain any type or backflow prevention device of a given manufacture as a respresentative of the manufacturer.

2.6 "Committee" means the Certification Committee appointed by the California-Nevada Section, A.W.W.A., and functioning as described herein, and in whom the responsibility for implementing and administering this program is vested.

2.7 "Inspection" shall mean the physical examination and testing of a backflow prevention device to verify that the backflow prevention device is functioning properly to prevent any backflow.

2.8 "Potable water system" shall mean the public water supply as well as the potable water systems within the water consumers premises.

2.9 "Repair" shall mean the return of a backflow prevention device to its proper working condition by a certified backflow prevention device tester.

2.10 "Section" means the California-Nevada Section, American Water Works Association (A.W.W.A.).

3. *Requirements for Certification*

3.1 Competency in all phases of backflow prevention device testing and repair must be demonstrated by means of education and/or experience and examination in order to be a certified backflow prevention device tester. The following are minimum requirements:

A. Educational experience—the candidate for certification shall have successfully completed an approved course of instruction in the theory, design, performance, and repair of backflow prevention devices; or

B. Show an acceptable two years of experience in the testing and maintenance of backflow prevention devices; or

C. A suitable combination of education and experience.

4. *Examination*

4.1 The Committee shall prepare such written and performance examinations as will properly reflect the knowledge and ability required of the classes of certification established.

4.2 The Committee may, at its discretion, require a comprehensive written or performance examination, or both, for a qualified person requesting certification in any classification.

4.3 The Committee shall hold examinations at times and places throughout the year as may be required and convenient.

4.4 In the event an applicant fails to appear for a scheduled examination, without prior excuse by the Administrator, he will be required to file a new application and filing fee.

4.5 In the event an applicant fails to pass an examination, he may apply for re-examination after a lapse of six months upon submission of new application and filing fee.

4.6 The Committee may, at its discretion, waive examination for applicants holding certificates or licenses issued by any organization having equivalent standards as determined by the Committee, and issue a class of certification in accordance with the requirements of this Committee.

4.7 The Committee may, at its discretion, waive examination of experienced backflow prevention device testers who have made substantial contributions to the betterment of the water industry and other persons holding valid certificates or licenses of equivalent class. Such applicants must submit a completed application along with a resume of work experience and educational background to the Committee, and upon approval after review they may be certified as a backflow prevention device tester and issued a class of certificate in accordance with the findings of the Committee.

4.8 The candidate for Certified Backflow Prevention Device Tester will be examined in two parts:

A. A written examination covering knowledge of the theory of backflow prevention, plumbing codes, device construction, testing and repair procedures, and other related areas; and

B. A performance examination showing a thorough understanding of the behavior and performance characteristics of backflow prevention devices.

5. *Certificates and Renewals*

5.1 Upon satisfactory fulfillment of the requirements provided herein, the Committee will issue a suitable certificate in behalf of the Section. The certificate will state the class of certification for which the applicant is certified.

5.2 The certificate shall indicate that the holder is Certified Backflow Prevention Device Tester.

5.3 The certificate shall be signed by the chairman of the California-Nevada Section, A.W.W.A., and the chairman of the Certification Committee.

5.4 The certificate shall bear the seal of the American Water Works Association.

5.5 Any certificate issued in accordance with these regulations shall be valid for a period of three years from date of issuance, except as hereinafter provided. At the end of that time the certificate may be renewed for a period of three (3) years, upon receipt by the administrator of a completed renewal application; and

A. Evidence of attendance at upgrading seminars to acquaint the applicant with the latest developments in the field of Cross-Connection Control. Such attendance at upgrading seminars shall be within one (1) year of the renewal date; or

B. Successfully pass a renewal written examination; and/or

C. Demonstrate competency in the proper testing and maintenance techniques of backflow prevention devices.

5.6 The Committee may, at its discretion, establish requirements in connection with the issuance of any renewal.

5.7 Certificate holders who leave employment as backflow prevention device testers may obtain renewal cards for a period not to exceed three years, after which their certificates will be considered as revoked.

5.8 Reapplication will be required, and re-examination may be required, for reinstatement of revoked certificates.

5.9 The Committee shall revoke the certificate of any person who, after a hearing before the Committee, shall be found to have obtained a certificate by fraud or deceit or displays gross negligence, incompetency, or misconduct in the performance of his duties as a certified backflow prevention device tester.

5.10 The Committee shall hear and decide any and all appeals associated with these rules.

6. *Testing Equipment*

6.1 Each backflow prevention device tester shall have at his disposal and be thoroughly familiar with the following test equipment to be used in the evaluation of the performance of the several types of devices:

A. Differential pressure gauges — used with reduced pressure principle devices and pressure vacuum breakers.

B. Duplex bourdon gauges — used with double check valve assemblies.

7. *Procedure for Certification*

7.1 Applications for certification shall be submitted to the Committee at least 30 days prior to the time set for the examination on forms prescribed by the Committee.

7.2 The Committee, with prior approval from the Executive Committee of the California-Nevada Section, A.W.W.A., shall have power to modify the classifications and requirements provided herein as needed, except that no change in classification or requirements shall be effective until 90 days after it has been announced. In all instances, requirements shall include an examination, as well as experience and educational qualifications.

8. *Appointment of Committee*

8.1 The Committee shall be appointed by the Chairman of the California-Nevada Section and shall serve for a period of one year unless reappointed. The Chairman of the Committee shall be designated by the Chairman of the California-Nevada Section.

8.2 The majority of the Backflow Prevention Device Testers' Subcommittee shall be made up of members of the Backflow Problems Committee.

9. *Fees for Certification*

9.1 The application fee for certification examination in any class shall be ten dollars ($10.00) payable to the "California-Nevada Section, A.W.W.A."

9.2 The fee for applicants residing out of the area of the California-Nevada Section shall be fifteen dollars ($15.00).

9.3 The application fee shall accompany the completed application form. The Administrator shall deposit all fees to the Section's general account or forward all fees to the treasurer of the California-Nevada Section for deposit in the Section's general account. The fee shall not be returned to the applicant because of failure to qualify for certification.

9.4 Fees for the renewal of a valid certificate shall be five dollars ($5.00).

9.5 Fees shall accompany the applications for certification or renewal.

10. *Certification Without Examination*

10.1 For persons holding valid local agency certification at the time of the adoption of this document, the Committee may waive part or all of the aforementioned examination procedure, subject to the filing of an application by said person within one (1) year from the adoption of the document.

ACKNOWLEDGEMENT

These revised guidelines were developed by the American Water Works Association, California-Nevada Section, Reclaimed Water Committee. This revision effort reflects the efforts of all of those who have served on the committee during the five year revision process. Those members' efforts are gratefully acknowledged by the three chairmen who have served during this work.

FOREWORD

Many communities in the United States are, or soon will be, reaching the limits of their available water supplies. Recent droughts in California have focused the attention of the entire country on the need for water conservation and reuse. Conventional conservation measures may enable communities to defer the need to develop additional water resources for a few years. However, use of nonpotable surface and groundwater supplies along with water reclamation and reuse will be a necessary part of any long-term water management plan.

By definition, nonpotable water is not safe for human consumption. Because of this different quality, it is important that the guidelines contain information which minimizes or eliminates the possible misuse of the water. This special attention is needed to protect the user and is consistent with other similar public health protection principles, such as backflow protection and water-to-sewer line separation.

To fulfill the necessary requirements for the use of nonpotable water, the potable water purveyor and the nonpotable water supplier must establish a cooperative responsibility to obtain and maintain water quality and system separation.

DISCLAIMER

This manual is only a guideline and does not constitute a legal or binding agreement between responsible parties from which liability could occur.

Since the regulatory agencies have jurisdiction over use of nonpotable water, additional specific requirements for individual users as well as for distribution entities may apply.

The AWWA California-Nevada Section has developed and published these guidelines for anyone involved in the use or distribution of nonpotable water. These guidelines are not intended to be used in place of local laws, regulations, or the design by engineers necessary to implement, construct, and use nonpotable water. The AWWA California-Nevada Section assumes no responsibility for the use of these guidelines. Any local agency or water professional using these guidelines should carefully study local circumstances and make additions or deletions as necessary for their individual needs.

SECTION 1

INTRODUCTION AND DEFINITIONS

1.1. PURPOSE OF GUIDELINES

The purpose of these guidelines is to provide guidance for planning, designing, constructing, and operating nonpotable water systems delivering reclaimed or other nonpotable water to multiple customers. The guidelines do not address the use of "Gray Water" or on-site treatment systems. However, ideas presented herein can be utilized by gray water or on-site users to protect the public health.

These guidelines are organized in six sections and are followed by appendices. The first section provides a brief introduction to the nonpotable water system. The second, third, and fourth sections provide design criteria for the construction of the offsite transmission, storage, pumping, and other facilities. The fifth section provides design and operating requirements for the water user's on-site facilities. The sixth section provides a description of the system management required to assure continued compliance with applicable State and local laws.

1.2. INTRODUCTION TO THE NONPOTABLE WATER SYSTEM

The nonpotable water systems referred to in these guidelines consist of the pumping, distribution, storage, and other facilities necessary to supply nonpotable water from its source to its point of use on the customer's property. The nonpotable water may be reclaimed water or a surface or groundwater supply not approved for potable water use. In a multiple supply system, potable water and nonpotable water can be used for irrigation and industrial purposes.

1.2.1. Planning Requirements: Any agency considering water reclamation and reuse or use of other nonpotable water supplies should start with a staged planning

07844

085441

program to determine the feasibility of a nonpotable water system. The planning program should involve three stages: preliminary investigations, screening of potential resources and markets, and detailed evaluation of facilities alternatives to serve selected markets, including engineering and economic feasibility, financial analysis, and environmental analysis.

The preliminary investigation stage is a fact-finding phase in which physical, economic, institutional and legal limitations should be identified. All potential sources of nonpotable water and its markets should be identified. The regulatory agencies should be consulted to determine quality requirements for a nonpotable water system. The screening of potential markets should consist of a comparison between the unit costs of potable water and of nonpotable water to the same market. The costs and pricing constraints should be evaluated under both present and future conditions to ensure that initial capital costs do not overshadow long term benefits. Present and future quantity and quality requirements should also be taken into consideration to determine if it is, and will remain, cost-effective to serve users nonpotable water. Reliability of supply, value of reclaimed water nutrients, and social benefits should also be considered, as well as possible savings in the potable system due to the reduced demand on it.

The final stage of the planning program is the detailed evaluation of the selected markets. In this stage, by looking in more detail at the conveyance routes and storage requirements of each alternative system to serve selected markets, refinements to preliminary cost estimates for delivery of nonpotable water can be made. Funding options can be compared, user costs developed, and a comparison made between the unit costs of potable and nonpotable water for each alternative system. It should also be possible to assess in more detail the environmental, institutional, and social aspects of each alternative.

These various planning stages should lead to a conceptual plan which could be the basis for the design and construction of the proposed system.

1.2.2. **Water Quality Assumptions:** For the purposes of these guidelines, it is assumed that the nonpotable water to be delivered meets the water quality requirements imposed by the regulatory agencies for the planned uses.

The quality of the nonpotable water must be protected from degradation from source to consumer. Inferior or degraded water quality could present public health hazards or not be of suitable quality for its intended use.

1.3 DEFINITIONS

Agency — The distributor of the nonpotable water.

Agency Supervisor — Persons designated by the distributor of nonpotable water who is responsible for operation and maintenance of the nonpotable water distributed system, prevention of cross-connection, and surveillance of all nonpotable water users.

Air-Gap Separation — A physical break between a supply pipe and a receiving vessel. The air gap should be at least double the diameter of the supply pipe, measured vertically above the top rim of the vessel, and in no case less than one inch.

ANSI — American National Standards Institute.

ASTM — American Standards for Testing Materials.

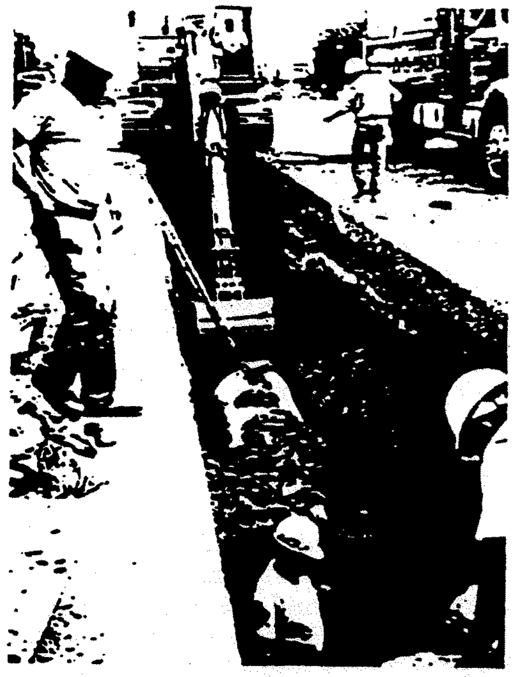
Applicant — Any person or authorized representative, firm, corporation, association, or agency who applies for nonpotable water service. The successful applicant becomes a user.

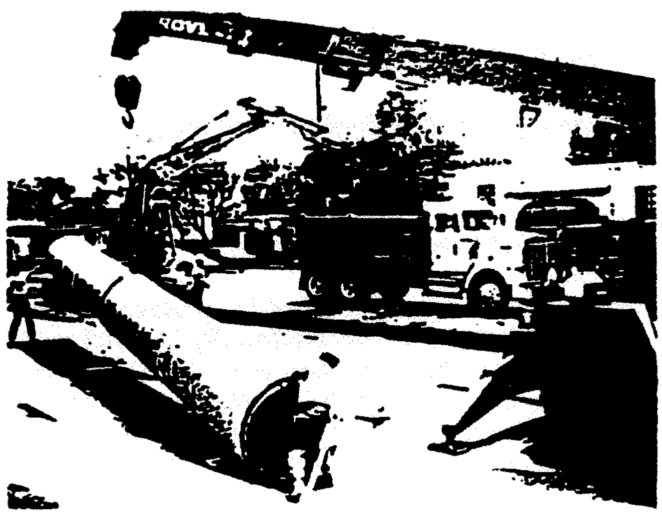
Application Rate	The rate at which water is applied to an irrigation or construction area, expressed in inches per hour.
Approved Use Area	A site with well defined boundaries, designated in a user permit issued by the agency, to receive nonpotable water for an approved use and in conformance with regulations of all applicable regulatory agencies.
Automatic System	Automatic controllers, valves, and associ ated equipment required for the program ming of effective water application rates when using nonpotable water.
AWWA	American Water Works Association.
Color Codes	Colors specified by the agency to differentiate various types of facilities (e.g.: potable from nonpotable water systems).
Contractor	A person, persons, or firm entering into a legal agreement with the agency or applicant for the performance of work on any portion of facilities subject to these guide lines.
Cross-Connection	An unprotected actual or potential connection between a potable water system used to supply water for drinking purposes and any source or system containing unapproved water. Bypass arrangements, jumper connections, removable sections, swivel or changeover devices, or other devices through which backflow could occur, should be considered to be cross-connections.

Distribution Line	For the purposes of this document distribution lines shall include all pipelines transporting non-potable water including transmission, distribution, and any other piping.
Gray Water	Wastewater other than toilet and/or urinal wastes which is reused on the premise.
Infiltration Rate	The rate at which soil will accept water.
Nonpotable Water	Any water, including reclaimed water, not meeting current potable water standards. Water which is suitable for beneficial uses excluding human consumption. Specifically excluded from this definition is "Gray Water".
Nonpotable Water System	A system serving water that is considered unsafe or aesthetically unacceptable for human consumption.
Offsite Facilities	Agency's nonpotable water facilities up to and including the water meter.
On-site Facilities	User's nonpotable water facilities down stream from the water meter.
Overspray	Water which is transmitted through the air to a location other than for which the direct application of reclaimed water is intended.
Pantone	Color standard system.
POC	Point of Connection.
Ponding	Retention of piped water on the surface of the ground or man-made surface for a period of time following the cessation of an approved reclaimed water use activity such that potential hazard to the public health may result.

Potable Water	Water which is pure and wholesome, will not endanger the lives or health of human beings, and conforms to the quality stan dards of Federal, State and local authorities for human consumption.
Potable Water System	A system serving potable water.
PVC Pipe	Polyvinyl chloride pipe.
Reclaimed Water	Water which, as a result of treatment of domestic wastewater, is suitable for a direct beneficial use or a controlled use that would not otherwise occur. Specifically excluded from this definition is "Gray Water".
Record (as-built) Drawings	Engineering plans that correctly show (1) all on-site and offsite nonpotable water facilities as constructed or modified and (2) all potable water lines and sewage lines.
Reduced Pressure Principle Backflow Prevention Device (RPPD)	A backflow preventer incorporating not less than two check valves, an automatically operated differential relief valve located between the two check valves, a tightly closing shut-off valve on each side of the check valve assembly, and equipped with necessary test cocks for testing.
Regulatory Agency	Those public agencies legally constituted by the State to protect health and water quality.
Runoff	Flow of water along the surface of the ground or other natural or manmade surfaces, including but not limited to pedestrian walkways, streets, playground surfaces, and grassy slopes.

Sealing Water	Independent water supplies to pump seals which provide sufficient sealing pressure and priming.
Spray Irrigation	Application of water for irrigation by spraying.
Unauthorized Discharge	Any release of nonpotable water that violates the regulations of the agency or any applicable Federal, State, or local statutes, regulations, ordinances, and contracts.
User (customer)	Any person, firm, corporation, association or agency receiving nonpotable water service.
User Permit	A permit issued by the agency to the applicant after the satisfactory completion of the procedure set forth in these guide lines. This permit constitutes a service agreement which legally binds the user to all applicable regulatory agencies' requirements.
User Supervisor	A qualified person designated by the user (customer) and approved by the agency who should be responsible for the installation, operation, and maintenance of the user on-site facilities, the prevention of cross-connection, and compliance with the local agency.
Windblown Spray	Dispersed, airborne particles of water transmitted through the air to a location other than that for which the direct application of reclaimed water is approved.





07851

SECTION 2

DISTRIBUTION LINES

This section is intended to provide criteria for protection against the misuse of distribution facilities. Cross-connection control is needed to prevent a nonpotable main from mistakenly being connected to a potable system. Therefore, the location, depth, mode of identification, and types of above-ground appurtenances such as air/vac assemblies, blow-offs, etc., should be studied carefully in order to avoid cross-connections or inappropriate uses with potable water use.

2.1. PRESSURE

Pressure requirements should be based on system design and practice. In any case, minimum pressure at the user's meter should be maintained at the peak demand hour. It is desirable that a pressure differential of 10 psi or greater be maintained with the potable water supply having the higher pressure.

2.2. MINIMUM DEPTH

The top of the pipe should be a minimum of 36-inches below the finished street grade.

2.3. MINIMUM SEPARATION

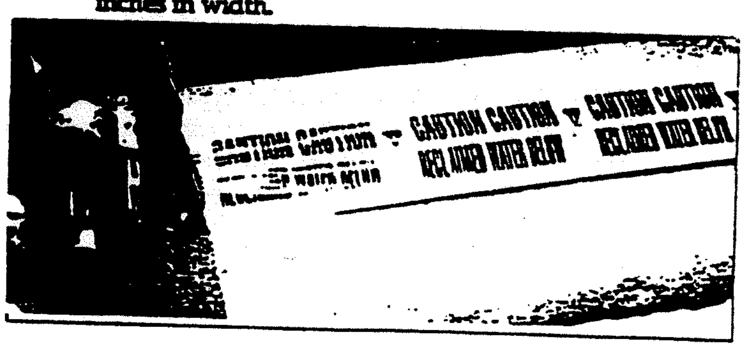
Nonpotable water lines parallel to potable water lines should be installed at least ten feet horizontally from and one foot lower than the potable water lines. Nonpotable water lines should cross a minimum of one foot below potable water lines. Where separations cannot be maintained, special construction requirements should be provided in accordance with health department requirements.

2.4. PIPE IDENTIFICATION

2.4.1. General: All new buried distribution piping in the nonpotable water system, including service lines, valves, and other appurtenances should either be colored purple, Pantone 522, and embossed or be integrally stamped/ marked CAUTION: NONPOTABLE WATER - DO NOT DRINK, or CAUTION: RECLAIMED WATER - DO NOT DRINK, or be installed with a purple identification tape, or a purple polyethylene vinyl wrap, color to be Pantone 512.

Existing potable water lines that are being converted to nonpotable use should first be accurately located and tested in coordination with regulatory agencies. If required, the necessary actions to bring the water line and appurtenances into compliance with regulatory standards should be taken. If the existing lines meet approval of the water supplier and regulatory agency, except for the pipe identification, the lines should be approved for nonpotable distribution. If verification of the existing lines is not possible, the lines should be uncovered, inspected, and identified prior to use.

2.4.2. Identification Tape: Identification tape should be prepared with white or black printing on a purple field, color Pantone 512, having the words "CAUTION: NONPOTABLE WATER - DO NOT DRINK", or "CAUTION: RECLAIMED WATER - DO NOT DRINK". The overall width of the tape should be at least three inches in width.



07853

085450

Identification tapes should be installed on the top of the transmission pipe longitudinally and should be centered. The identification should be continuous in their coverage on the pipe and should be fastened to each pipe length no more than ten feet apart. Tape attached to sections of pipe before they are placed in the trench should have flaps sufficient for continuous coverage. Other satisfactory means of securing the tape during backfill of the trench may be used if suitable for the work, as determined by the agency.

Color coded identification (caution) tape differentiating the nonpotable piping from other utility lines should be consistent throughout the service area.

2.5. VALVE BOX AND OTHER SURFACE IDENTIFICATION

2.5.1. General: Valve boxes should be the standard concrete or fiberglass box with a special triangular, heavy-duty cover. All valve covers on offsite nonpotable transmission water lines should be of non-interchangeable shape with potable water covers and with a recognizable inscription cast on the top surface.

2.5.2. Identification: All above ground facilities should be consistently color-coded (purple, Pantone 512) and marked to differentiate nonpotable water facilities from potable water or wastewater facilities.

2.6. BLOW-OFF ASSEMBLIES

Either an in-line type or end-of-line type blow-off or drain assembly should be installed for removing water or sediment from the pipe. The line tap for the assembly should be no closer than 18-inches to a valve, coupling, joint, or fitting unless it is at the end of the line. If there are restrictions on discharge or runoff, the regulatory agencies should be consulted to find an acceptable alternative.

SECTION 3

STORAGE AND SUPPLY

Because there are daily and seasonal imbalances between nonpotable water supply and demand, storage facilities may be needed in the nonpotable water system. In addition to operational storage, when reclaimed water is used as the primary source of supply, there is generally a need for seasonal storage because wastewater treatment is a continuous operation while the majority of reuse applications are seasonal in nature.

3.1. SEASONAL STORAGF

When considering the size of the reservoirs to meet irrigation requirements, open reservoirs may prove to be the most economical alternative. However, algal growth and suspended solids from open reservoirs have been recognized as sources of particles which may clog the sprinkler system. Most sprinkler system control valves and sprinkler heads can readily pass particles which go through a 30-mesh screen. This corresponds to a screen opening of 0.0233 inch or 600 microns. It is recommended that all irrigation water that enters the distribution system from open reservoirs be filtered through a filtration process similar in performance to the filters used at the reclamation plant or, as a minimum, screened through a micro strainer with a 200-mesh screen. The use of a very fine strainer or filter will maximize the suspended solids' removal at central reservoir sites and reduce any special maintenance of the local sprinkler systems.

If nonpotable water is used for filling recreational lakes or for other applications where particulates and turbidity may be troublesome, sand filtration or multimedia filtration may be more appropriate than micro screening. Suggested solutions to control the algal growth include, but are not limited to, covering the reservoir, operating at a low detention time, or adding acceptable chemicals that control growth.

3.2. OPERATIONAL STORAGE FACILITIES

The purpose of operational storage is to provide a continuous supply of water during periods of down time at the treatment plant, meet peak daily fluctuations in water demands, and allow for optimum plant operation. The size of the storage facilities depends on the degree of fluctuation and availability of supplemental supplies. Frequently, the reservoir is constructed to save cost by reducing peak period pumping charges and treatment plant construction cost by not sizing for peak demands. If there are supplementary sources to meet peak demands, smaller operational storage facilities may be used to control supplies into the distribution system. Operational storage facilities should be sized to hold at least one and one-half to two times the average summer day demand volume.

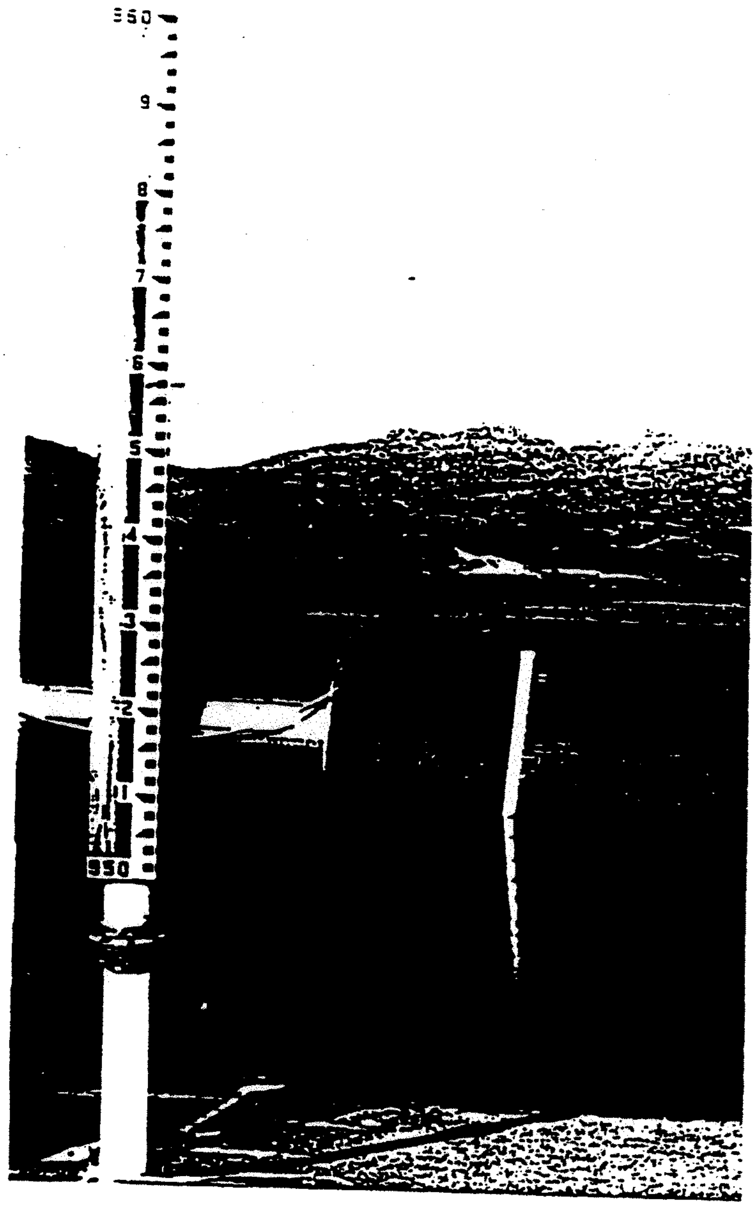
3.3. EMERGENCY STORAGE AND SUPPLY (includes backup supply)

The distribution system requires supplementary sources to meet its demand in case of a plant upset or main supply interruption. Each system's required storage capacity will be different, depending on the reliability of treatment processes, peak summertime demands, availability of other sources, the proposed reliability of the system, and the ability to recover to normal conditions.

Seasonal or operational storage facilities may be able to meet emergency storage requirements, depending on their storage capacities. If a system is lacking necessary emergency storage capacity, it should have at least one reliable supply source to meet its demand.

3.4. FENCING

Nonpotable water supply reservoirs, which are closed to the public, should be enclosed within a fenced area or other enclosure



9
8
7
6
5
4
3
2
1
950

that will restrict public access. This public safety feature should also minimize potential detrimental effects resulting from vandalism or animals.

3.5. IDENTIFICATION

All storage facilities should be identified by signs containing the words "WARNING: NONPOTABLE WATER - DO NOT DRINK" or "WARNING: RECLAIMED WATER - DO NOT DRINK", and contain the universal symbol for do not drink. The signs should have a purple background, Pantone 512, with high contrast color lettering. An adequate number of signs in English and other primary languages spoken in the area should also be posted on the surrounding fence and at the entrance of each facility.

SECTION 4

PUMPING

Agencies with pumping facilities to distribute nonpotable water should make special provisions to identify the type of water being handled, provide acceptable backflow protection, avoid release of nonpotable water in an uncontrolled manner, and provide for proper drainage of the packing seal water.

4.1. MARKING

All exposed and above ground piping, fittings, pumps, valves, etc. should be painted purple, Pantone 512. In addition, all piping should be identified using an accepted means of labeling reading, "CAUTION" NONPOTABLE WATER - DO NOT DRINK" or "CAUTION: RECLAIMED WATER - DO NOT DRINK". In a fenced pump station area, at least one sign should be posted on the fence which can be readily seen by all operations personnel using the facility.

4.2. SEALING WATER

Any potable water used as seal water for nonpotable water pump seals should be adequately protected from backflow.

4.3. SURGE PROTECTION

All pumping systems should have proper surge protection facilities to prevent damage resulting from broken piping resulting from water hammer and pressure surges.

07860

085457

SECTION 5

ON-SITE APPLICATIONS

Nonpotable water facilities may require special accessories. Because of suspended matter which may accumulate from open storage or other sources, water strainers may be required before any meter facility or other mechanical type of device such as a pressure-reducing valve. Since irrigation operations are frequently at night, automatic electronic controllers should be used on-site. Backflow prevention is required when a nonpotable water system shares a use area with a potable system. This must be accomplished with the approval of appropriate health agencies. Facility identification is as important as the separation considerations discussed earlier. Pipelines, equipment and irrigated areas should be clearly identified.

5.1. STRAINERS AT METER/POINT OF CONNECTION

5.1.1. General: Depending on the quality of the nonpotable water and type of storage utilized, strainers may be required at the consumer's meter.

5.1.2. Type: Strainers of the following types are generally satisfactory.

A. Wye strainers: Not recommended for below-ground (in vaults) installations.

B. Basket strainers: Suitable for above or below-ground (in vaults) installations.

C. Filter strainers: Normally used above ground on drip irrigation systems.

5.1.3. Placement: Strainers are normally the same size as the line and can be installed either before or after the meter.

A. Before meter: Installation before the meter will protect the meter as well as the on-site system. Maintenance in this case is the responsibility of the water purveyor.

B. After meter: Installation after the meter will not provide meter protection, and maintenance in this case is usually not the responsibility of the purveyor. It should be determined in advance whether there is a potential for debris in the water that would plug the screen in the meter.

Strainers can range in mesh size from 20 to 325. A mesh of 20 to 80 is normally adequate. An analysis of potential debris will aid in prescribing the optimum size. In order to reduce maintenance, material that will not plug on site irrigation nozzles should normally be allowed to pass.

5.2. CONTROLLERS

Controllers are used to automatically open and close on-site distribution valves.

A. They should be fully automatic.

B. They should have multiple starting times that can be selected for any time of day, seven (7) days a week, and should be equipped with moisture sensors to avoid activation during rainy periods.

C. Station durations should be capable of delivering water from one minute to 60 minutes per each start time.

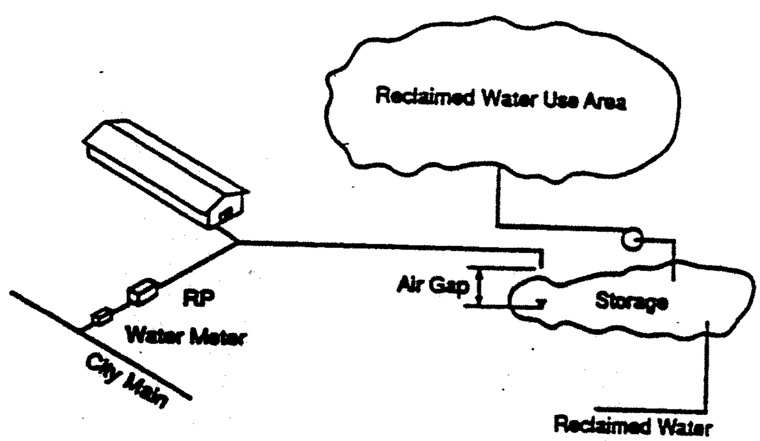
D. An appropriate sized drawing of the area served by the controller should be sealed in a plastic cover and placed in the controller and updated if the system is changed.

E. Controllers of nonpotable water should be color-coded to differentiate the nonpotable water from the potable water in accordance with Section 2.4.1. and Section 2.4.2.

F. Controllers should be labeled inside and outside, warning that the system is utilizing nonpotable water. The labels should also alert the system's owner/maintenance personnel of any important constraints on the operation of the system in accordance with Section 2.4.1. and Section 2.4.2.

5.3. BACKFLOW PROTECTION

If a connection between potable and nonpotable water systems is necessary, an approved air gap must be provided to protect the potable water system.



If a premises is supplied with both potable water and nonpotable water, then backflow protection with an approved air gap (AG) must be provided at the potable water service connection. A reduced pressure principle device (RPPD) backflow prevention

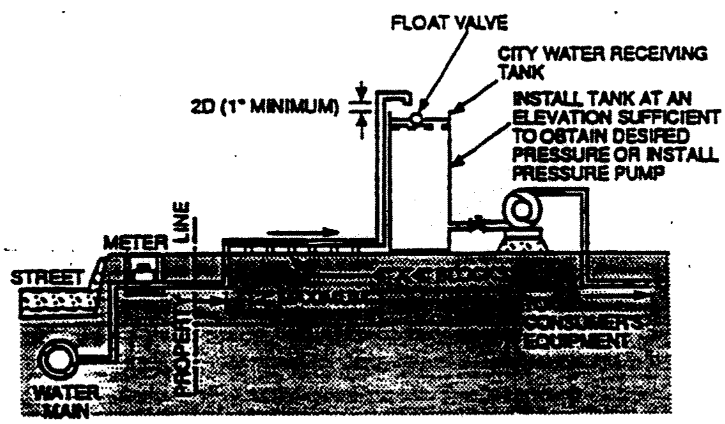
07863

085460

device may be provided only when approved by the health department and potable water supplier.

Backflow prevention devices are not normally used on nonpotable water systems. However, an agency should maintain the water quality in a nonpotable distribution system. A backflow prevention device may therefore be needed at a specific meter where on-site exposures would impact the quality of the nonpotable supply. If temporary potable water connections to the nonpotable water system are required, the connections should be protected in the same manner as a permanent connection. Exceptions may be necessary under special circumstances, but in any case, should not be allowed unless approved by the potable water supplier and regulatory agencies.

5.4 PIPE IDENTIFICATION



AIR-GAP SEPARATION

New on-site pipelines should be identified as nonpotable water pipes by using a purple color code, Pantone 522 for pipe and other appurtenances, Pantone 512 for marking tapes, labels, signs, etc., and markings, differentiating them from potable water piping.

All piping and valves must also be appropriately labeled or continuously taped with appropriate identification.

When an existing potable water line is converted to nonpotable usage, the water line should be accurately located and tested in coordination with regulatory agencies. If required, necessary actions should be taken to bring the water line and appurtenances into compliance with regulatory standards. If the existing line meets the approval of the water supplier and regulatory agency, except for the pipe identification, the line should be approved for nonpotable distribution. If verification of the existing line is not possible, the line should be uncovered, inspected, and identified prior to use.

5.4.1. Warning Tape: A warning tape should be installed on pressure and/or non-pressure laterals. A purple tape, Pantone 512, with black or white lettering stating "CAUTION: NONPOTABLE WATER - DO NOT DRINK" or "CAUTION: RECLAIMED WATER - DO NOT DRINK" should be fastened directly to the top of the pipe. The tape should run continuously the entire length of the pipe and should be at least 3-inches in width. It is recommended that the identification tape be locator type marking tape.

5.4.2. Colored Pipe: The use of purple colored pipe, color Pantone 522, or purple polyethylene vinyl wrap, Pantone 512, with the words "CAUTION: NONPOTABLE WATER - DO NOT DRINK" or "CAUTION: RECLAIMED WATER - DO NOT DRINK", printed on the pipe, or tape, is an acceptable alternative. The warning should be stamped on opposite sides of the pipe, repeated every three feet.

5.5. SYSTEM IDENTIFICATION

A nonpotable water system should be identified in such a manner as to differentiate it from a potable water system.

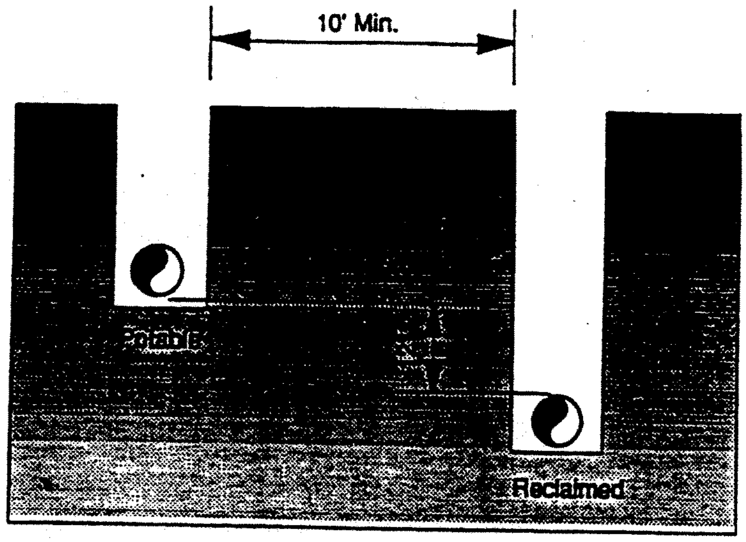
5.5.1. Hose Bibs: Hose bibs should not be allowed on nonpotable irrigation systems. Quick couplers should be used if hose connections are necessary. Fittings should prevent interconnection between the potable and nonpotable systems. Hoses used with the nonpotable system should not be usable with potable water systems. Signs should be used to identify the nonpotable quick coupling. When potable quick couplers are within 60 feet of the nonpotable system, both should be equipped with appropriate signs.

5.5.2. Potable Water System Lines: When potable water is being supplied to an area also being supplied with nonpotable water, the potable water main should also be identified. A warning tape with the words "CAUTION—DRINKING WATER LINE" should be fastened directly to the top of the potable water pipe and run continuously the entire length of the pipe. This tape should be at least 3-inches in width. The color code should differentiate potable water from nonpotable water.

5.6. PROXIMITY OF UTILITIES

5.6.1. Horizontal Separation: A 10-foot separation of the nonpotable water pipe should be maintained at all times between a potable water pipe and/or a parallel sanitary sewer system. If a 10-foot separation is not possible, special construction methods should be considered. Common trench construction should not be permitted. In any event, a minimum of a 4 foot horizontal separation should be maintained.

5.6.2. Vertical Separation: The potable water pipe should be installed a minimum of one foot above the nonpotable water pipe, which in turn, should be installed a minimum of one foot above a sanitary sewer system. If a one foot separation is not possible, the approval for special construction requirements should be obtained from the regulatory agencies.



5.7. DRINKING FOUNTAINS/PUBLIC FACILITIES

Potable water drinking fountains and other public facilities should be placed out of the irrigation area in which nonpotable water is used, or otherwise protected.

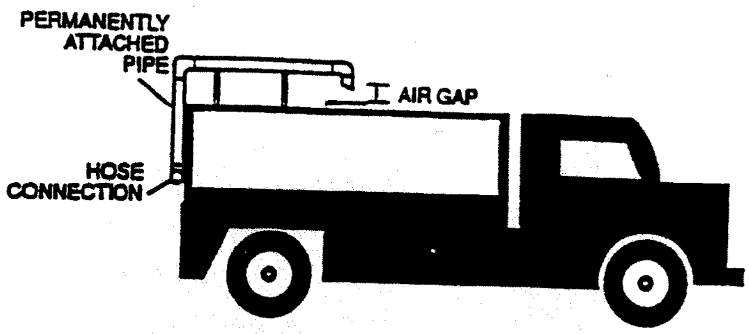
Exterior drinking fountains and other public facilities should be shown and called out on the construction plans. If no exterior drinking fountains, picnic tables, food establishments, or other public facilities are present in the design area, then it should be specifically stated on the plans that none are to exist.

5.8. CONSTRUCTION WATER

Water trucks, hoses, drop tanks, etc. should be identified as containing nonpotable water and not suitable for drinking.

07867

085464



5.8.1. Permits: The use of nonpotable water for construction purposes requires approval of the appropriate regulatory agencies. Sufficient time should be allowed to acquire the necessary permits prior to beginning construction.

5.8.2. Uses: Nonpotable water used for construction purposes may be used for soil compaction during grading operations, dust control and consolidation and compaction of backfill in nonpotable water, sanitary sewer, storm drain, gas and electric pipeline trenches. Reclaimed water may not be suitable for water jetting and consolidation or compaction of backfill in potable water pipeline trenches.

5.8.3. Equipment: Equipment operators should be instructed about the requirements contained herein and the potential health hazards involved with the use of nonpotable water.

Nonpotable water should not be introduced into any domestic water piping system. No unprotected connection should be made between equipment containing nonpotable water and any part of a domestic water system.

5.8.4. Ponds: Ponds used for storage of construction nonpotable water should be fenced and posted to limit public access.

07868

085465

5.9. SPECIFIC PROVISIONS

Some restrictions are placed on the operation of nonpotable water systems as a matter of good practice and to protect public health. The following restrictions applied by the regulatory agencies should be included in the detailed design:

5.9.1. Runoff Conditions: Conditions which directly or indirectly cause a runoff outside of the approved use area are prohibited.

5.9.2. Ponding Conditions: Conditions which directly or indirectly cause ponding (puddles of standing water) outside of or within the approved use area are prohibited.

5.9.3. Overspray Conditions: Conditions which directly or indirectly permit windblown spray or overspray to pass outside of the approved use area are prohibited.

5.9.4. Unapproved Uses: Use of nonpotable water for any purpose other than those explicitly approved in the currently effective user permit issued by the operating agency, and without the prior knowledge and approval of the appropriate regulatory agencies, shall be prohibited.

5.9.5. Reuse/Disposal in Unapproved Areas: Reuse/disposal of nonpotable water for any purpose, including approved uses, in areas other than those explicitly approved in the currently effective user permit issued by the operating agency, and without the prior knowledge and approval of the appropriate regulatory agencies, shall be prohibited.

5.9.6. Cross-Connection: Cross-Connections resulting from the use of a nonpotable water service, whether by design, construction practice, or system operations, shall be prohibited.

5.9.7. Hose Bibs: Hose bibs on nonpotable water systems shall be prohibited. Replacement of hose bibs with quick couplers is recommended. (See 5.5.1)

5.9.8. Food Establishments/Public Facilities: In order to prevent food from being exposed to spray from the irrigation system, nonpotable water irrigation systems should not be installed near food establishments or public facilities such as picnic tables and drinking fountains (see 5.7.).

5.10. IRRIGATION APPLICATION RATE AND PRACTICE

An irrigation system designed with nonpotable water should specify type of sprinkler, placement of sprinkler, type of soil, type of plants, slope, hardscape, etc., to be used so as to prevent runoff, ponding and overspray.

5.10.1.-Runoff: Nonpotable water should be applied at a rate that does not exceed the infiltration rate of the soil. The irrigation system should not be allowed to operate for a time longer than the landscape's water requirement. If runoff or ponding occurs before the landscape's water requirement is met, the automatic controls should be reprogrammed with additional watering cycles to meet the requirements and prevent runoff.

5.10.2. Irrigation Period: To the extent possible, the operation of the irrigation system should be during periods of minimal public use of the approved area. Such periods of operation should remain within any general period of nonpotable water irrigation operation specified by the agency.

5.11. EQUIPMENT AND FACILITIES

Any equipment or facilities such as tanks, temporary piping or valves, and portable pumps which have been used with nonpotable water should be cleaned and disinfected before removal from the approved use area for use at another job site. This disinfection and cleaning should ensure the protection of the public health in the event of any subsequent use as approved by the agency supervisor and the disinfection process should be performed in his or her presence.

5.12. WARNING SIGNS AND LABELS

Agency warning labels should be installed on designated facilities such as, but not limited to, controller panels and washdown or blow-off hydrants on water trucks, and temporary construction services. The labels should indicate that the system contains nonpotable water that is unsafe to drink.

Where nonpotable water is used for recreational impoundments, warning signs should be installed to notify that the water in the impoundment is unsafe to drink. A detailed plan should be prepared showing placement and spacing of the proposed signs. Where nonpotable water is used for irrigation, warning signs should be installed, and contain as a minimum, 1/2" black or white letters on a purple, Pantone 512, background notifying the public that the water is unsafe to drink.

Warning signs and labels should read "CAUTION: NONPOTABLE WATER - DO NOT DRINK", or "CAUTION: RECLAIMED WATER - DO NOT DRINK", and should be in both English and other language(s) common to the particular area. The signs should include the international system for do not drink.

SECTION 6

SYSTEM MANAGEMENT

Proper system management is crucial to protection of public health. Quality control, use control, operation and maintenance control, cross-connection prevention and assurance against violation of the agency requirements are some of the system management considerations.

6.1. QUALITY CONTROL

All nonpotable water delivered to users from agency facilities should conform to requirements established by the appropriate regulatory agencies.

6.2. CONTROL OF ON-SITE USE

6.2.1. On-site Use Requirements: Only after the appropriate applications have been filed and authorization has been granted by the appropriate agency shall nonpotable water be furnished for the intended uses.

6.2.2. User Supervisor: The user should include in the application for nonpotable water service the following information regarding the individual designated as user supervisor: name, address, and telephone number at which this individual or designated representative can receive messages during "off hours." The agency should approve the designated person, or reject the designation for just cause. It should be the responsibility of the user to notify the agency of a change in designation of the user supervisor. Following such notification, the agency should again perform its evaluation.

The user supervisor should be aware of the entire system within his or her responsibility and of all applicable conditions of nonpotable water use. The user supervisor should be responsible for the installation, operation and maintenance of pipelines and cross-connection equipment.

6.2.3. Allowed Uses for Nonpotable Water: The uses of nonpotable water include landscape irrigation, agricultural irrigation, construction water, industrial process water, recreational impoundment, etc. Each such use should be considered for approval by the agency on a case-by-case basis.

Determination of allowed uses should be in accordance with the standards of treatment and water quality regulations of the State. The agency may set forth specific requirements as conditions prior to approving any such uses and/or require specific prior approval from the appropriate regulatory agencies.

6.2.4. Emergency Connections to Potable Water Systems: Permanent emergency connections to the potable water system are prohibited. A temporary connection to the potable water system under special emergency conditions may be made only after the agency has received approvals from the water purveyor, State and local health departments. (See 5.3).

6.2.5. Responsibility for Maintenance: Unless otherwise specified, the user is responsible for maintaining all on-site facilities (downstream of the user's service meter). Unless otherwise specified, all on-site facilities are under the ownership of parties other than the agency.

6.3. FACILITIES OPERATION (Also see Appendix A)

6.3.1. On-site Facilities: The user shall be responsible for the operation and surveillance of on-site domestic water distribution and nonpotable water distribution facilities to avoid cross-connections.

6.3.2. **Agency Supervisor:** The agency should designate an agency supervisor to be responsible for the operation of the offsite distribution system for the surveillance of all users and for the determination of water quality as it relates to compliance with requirements of regulatory agencies. The name and designated function of this individual should be listed by the agency in the service application form and should be kept updated at the agency office.

The agency supervisor should be knowledgeable of the entire system and of all applicable conditions of nonpotable water use. The agency supervisor should be the ontact person for the agency in all matters between the user and the agency and between the agency and the regulatory agencies concerning the operation of the nonpotable water system. The agency should require that the user supervisor obtain instruction in the use of nonpotable water, such instruction being provided or approved by the agency.

6.3.3. **On-site Nonpotable Water Facilities:** The operation and surveillance of all on-site nonpotable water systems facilities should be under the management of the user supervisor designated by the user and approved by the agency. The agency should have the right to enter upon the user's premises during reasonable hours for the purpose of inspecting the nonpotable facilities and their operation. The user should have the following responsibilities in relation to the operation of the on-site facilities:

A. Make sure that all operations personnel are trained in and familiarized with the use of nonpotable water.

B. Furnish the operations personnel with maintenance instructions, controller charts, and record drawings to insure proper operation in accordance with the on-site facilities design.

C. Prepare and submit to the agency required record drawings.

D. Notify the agency of any and all updates or proposed changes, modifications or additions to the on-site facilities. Changes should be approved by the agency and should be designed and constructed according to the requirements, conditions and standards set forth in the agency's requirements.

E. Insure that the nonpotable water facilities remain in accordance with the agency's requirements. (See 5.9).

F. Operate and control the system in order to prevent direct human consumption of nonpotable water and to control and limit runoff. The user should demonstrate responsibility for any and all subsequent uses of the nonpotable water.

G. Report to the agency any and all failures in the nonpotable water system that cause an unauthorized discharge of nonpotable water.

H. Comply with any and all applicable Federal, State and local statues, ordinances, regulations, contracts and requirements prescribed by the agency. In the event of violation, any charges and penalties may be applied and collected by the appropriate regulatory agency.

I. Install and maintain signs at all facilities.

6.4. NONPOTABLE WATER SYSTEMS

The agency should monitor and inspect the entire nonpotable water system including both on-site and offsite facilities. The agency should conduct system monitoring programs, maintain all systems as deemed necessary, and provide reports as requested by regulatory agencies. The agency, in monitoring, record keeping, and providing reports, should have the right to enter the user's premise during reasonable hours. The purpose of inspecting on-site nonpotable water facilities and areas of nonpotable water use is to assist the user in complying with requirements.

6.5. VIOLATIONS

6.5.1. Determination: The agency should reserve the right to determine whether a violation of the guidelines has resulted from any action or occurrence which is the responsibility of a user. If the violation constitutes a violation of any regulatory agency requirement, the agency should make its determination on behalf of the concerned regulatory agency. If a violation is verified, the agency should notify the user and confirm that it is corrected.

6.5.2. Specific Violations: Specific violations should include those which directly cause noncompliance with any one of the specific prohibitions as listed in the permit issued by the regulatory agency. However, by definition, noncompliance with any condition or conditions of the guidelines of the regulatory agency, whether willingly or by accident, should constitute a violation.

6.5.3. Notification: It should be the responsibility of the user to notify the agency of any and all failures in a nonpotable water system whether or not in the user's opinion the failures resulted in violations. It should also be the responsibility of the user to notify the agency of any and all violations which occur as a result of the user's action, the action of the operations personnel, or any use of the nonpotable water service. If there are any doubts regarding whether a violation has occurred, the user should notify the agency so that a determination can be made.

Notification of failures and violations should be made as soon as possible or, in any event, no later than noon on the next regular working day following the occurrence. Such notification should be made by telephone to the agency supervisor or designated representative.

6.5.4. Corrective Action: If the agency supervisor's investigation results in the determination that a violation has occurred, then it should be the responsibility of the user to initiate corrective action. A timetable for completing the corrections should be negotiated with the agency supervisor by the user, with the final approval of the agency. Such corrections may involve human factors, such as additional training or procedures modifications, as well as physical alterations to the system.

If corrective actions are required, the user should submit to the agency, in writing, a statement describing the violation or violations, summarizing the corrective action to be taken and setting forth the negotiated timetable. This written submittal should be received by the agency supervisor. Until the corrections are completed and approved by the agency, the use of nonpotable water should continue only to the extent permitted by the agency and other regulatory agencies.

The user should keep a written log of all system failures and violations, including corrective action taken. The log should be reviewed by the agency regularly.

6.5.5. Appeal: If the user believes there is just cause, he or she may appeal the determination of the agency supervisor to the agency. Such appeal should be presented in writing and should state the conditions which the agency supervisor has determined to be a violation and the user's opinion to the contrary. The action of the agency should be final.

6.5.6. Revocation: Failure to permanently cease all violations within the time stated should result in revocation of the user permit by the agency and termination of nonpotable water service.

6.6. PENALTIES

6.6.1. Authority: The agency should retain the authority to assess penalties against any nonpotable water user for just cause as determined by violations against any regulations, ordinances or contracts.

6.6.2. **Findings:** Depending on the nature of the violation and any resulting corrective action program, the user should be subject to penalty by the agency. Penalties should be assessed only by the agency or its authorized agent and be based on findings as presented by agency staff or as presented in the case of user appeal.

6.6.3. **Enforcement:** The responsibility for the enforcement of penalty assessments should rest with the agency staff. The staff should employ whatever legal means necessary to ensure that the agency's action is enforced.

APPENDIX A

ADMINISTRATIVE PROCEDURES

A.1. GENERAL

The following describes the required procedure for an applicant to obtain service from the agency for the proposed service area and to obtain approval for construction of facilities to be dedicated for operation and maintenance by the agency.

A.2. PRELIMINARY INVESTIGATION

The user should meet with the agency at the earliest possible date to determine whether the property to be developed is within the agency's nonpotable service boundaries. At this time, the availability of existing facilities should also be reviewed (It should be the responsibility of the user to request confirmation that the agency has sufficient capacity). In some areas, a preliminary feasibility investigation and report may be necessary. The user should file directly with the agency supervisor, a map describing the area to be served, the tentative tract map, plot plans, preliminary prints of streets, construction plans and such other materials as the agency may request for use in its investigation.

A.3. SERVICE APPLICATION

An application for nonpotable water service should be submitted to the agency only after the agency has received a report of preliminary investigation determining the feasibility of the proposed service. Approval for service should be indicated by the agency by issuing a user permit to the applicant. The user permit should come into force only after construction of the subject project is completed and final acceptance has been granted by the agency and approval for service start-up given.

The application for nonpotable water service should be made in writing and signed by the user, who may be the owner or authorized representative. The application form should be furnished by the agency and should request information concerning the applicant's company, the user's relationship to the subject property as legal owner, tenant, or lessee; the type of nonpotable water use; a boundary description of the property to be served; the purpose for which the properties to be served; the purpose for which the property is to be used; the estimated consumption of nonpotable water; the designation of user supervisor; any special conditions for service pursuant to these guidelines; and periods of intended use of nonpotable water. Certain technical information derived from the design and peculiar to the type of nonpotable water use may also be requested.

Upon receipt of an application, the agency should review the application and make such investigation as deemed necessary. The agency may prescribe specific requirements in writing to the user as to the design of the facilities, the manner of construction, the method of operations and the conditions of service. An evaluation should be performed which will establish that all information included on the form is consistent with the guidelines and the applicable requirements of the regulatory agencies.

A.4. CONTROL OF DESIGN

The agency should approve all nonpotable water system designs.

A.4.1. **Offsite Facilities:** The design of any portion of the offsite facilities and the preparation of plans and construction specifications should be approved by an engineer registered by the State.

It should be the responsibility of the user to meet with the agency in order to determine what requirements, if any, there may be for phasing stages of nonpotable water distribution line installation. It should also be the responsibility of the user to coordinate its activities with those of the agency in the development of the mainstream portions of the nonpotable water distribution system.

The agency should reserve the right to determine the size of the service connection and should also have the right to determine the kind and size of all appurtenances to the service including pressure reducing valve and water meter. The agency should make the service connection and install the meter with its own personnel or through contracted labor. All pressure reducing valves are to be installed and maintained by the user.

Other design requirements for offsite facilities should be found in the agency's design specifications. AWWA, ANSI and ASTM Standards are to be used for all materials.

A.4.2. **On-site Facilities:** The design of the on-site facilities and the preparation of plans and construction specifications should be the responsibility of a landscape architect or engineer registered with the State.

In those areas where water is not immediately available for use when the design area is ready for construction, the on-site facilities should nevertheless be designed to use nonpotable water. Provisions should be made and these guidelines followed to allow for connection to the nonpotable water system when it becomes available. In the interim, potable water should be supplied to the on-site facilities through an approved temporary potable water connection. An approved reduced pressure backflow prevention device should be required as long as the on-site facility is using potable water. This device should be provided and installed by the user to the satisfaction of the potable water supplier and the health department.

Only when the agency makes the connection to the nonpotable water system should the user remove the backflow preventer. All points of connection to the agency's offsite facilities should be determined by the agency. The local health department should be notified of all action taken with backflow prevention devices.

The on-site facilities should be designed to meet the peak moisture demand of all plant materials used within the design area and to apply irrigation water in a manner compatible with the infiltration rates of the soil types within the approved use area. Infiltration rates should be included with the design. The irrigation system should be designed to prevent discharge onto areas which are not approved for use and to prevent ponding and/or runoff.

Other design requirements for on-site facilities should be found in the agency's design specifications.

A.4.3. Construction Water Facilities: Service connections for the construction use of nonpotable water should be provided by the agency at locations convenient to the user but at the discretion of the agency. The service should include a valved connection to a nonpotable water distribution main and a water meter whose capacity should be determined by the agency from information supplied by the user in the user permit application. The agency should make the connection to the main and install the meter.

A.4.4. Conversion of Existing Facilities to Nonpotable Water: All facilities converted from a potable to a nonpotable facility should conform to these guidelines. The facilities to be converted should be investigated in detail, including review of any record drawings, preparation of required reports and determinations by the agency of measures necessary to bring the system into full compliance with guidelines.

The plans and specifications for the converted system should be submitted to and reviewed by the agency, State and local health departments.

A.5. EXAMPLE DESIGN AND INSPECTION CONTROL PROCEDURES

The following design and inspection control procedures should be considered as a guideline.

A.5.1.1. Master Development Plan: Before the agency can issue a preliminary will-serve letter for a proposed development, the user should submit two sets of tentative master development plans showing the plan of the proposed nonpotable water system for review and approval by the agency. The agency, when reviewing a preliminary nonpotable water system design for the planned development, should take into consideration the following:

A. Existing nonpotable water transmission main locations and sizes.

B. Agency's nonpotable water master development plan.

C. Agency's design specifications.

D. Applicant's irrigation requirements.

The agency should return one "red-lined" copy of the reviewed master development plan to the applicant showing any corrections and/or comments. The master development plan, as corrected, should then be considered approved by the agency; however, the user should make the corrections noted and should re-submit two sets of the revised plans to the agency.

A.5.1.2 Improvement Plans: The user should submit to the agency two sets of each of offsite and on-site (individual tract) nonpotable water system improvement plans for review and approval. The agency should return one "red-lined" set of the reviewed improvement plans to the user showing any corrections and/or comments. The user should make the corrections noted, should respond to the agency's comments appropriately and should provide the agency with copies of the required easements to the agency if recorded by separate instrument. Upon completing these requirements to the satisfaction of the agency, the user should bring the original drawings to the agency for signature of approval. Four sets of completely signed and approved nonpotable water system improvement plans should be furnished to the agency at least two working days before the required pre-construction conference prior to commencing work.

A.5.1.3. Pre-construction Conference: A pre-construction conference should be held at least 24 hours before starting construction. The contractor's working foreman and/or job superintendent, the user's tract superintendent and the agency's engineer and inspector should be present. The purpose of this meeting should be to resolve any questions on agency specification requirements to obtain the contractor's construction procedural schedule, and to disclose and discuss any known circumstances that might affect job installation.

A.5.1.4. Inspection of Work: All work should be subject to inspection by the agency and should be left open and uncovered until approved by the appropriate agency authority.

A.5.1.5. Agency Authority: The agency should at all times have access to the work during construction and should be provided reasonable assistance for ascertaining full knowledge regarding the process, workmanship and character of materials used and employed in the work. No pipe, fittings or other materials should be installed or backfilled until inspected and approved by the agency. The contractor should give due notice to the agency inspector in advance of backfilling as well as all other inspection phases so that proper inspection may be provided. Inspection of the work should not relieve the contractor any obligations to complete the work as prescribed by the agency's standards. Defective work should be made good before any testing or final inspection will be permitted. Any defective work or unsuitable materials may be rejected notwithstanding the fact that such defective work and unsuitable materials had been previously overlooked by the agency. The agency should have the authority to suspend the work wholly or in part for such time as it may deem necessary due to the failure of the contractor to carry out orders given by the agency inspector or to perform any provisions of the plans and specifications. The contractor should immediately comply with the written order of the agency to suspend the work wholly or in part. The work should be resumed only when methods or defective work are corrected as ordered and approved in writing by the agency.

A.5.1.6. Final Inspection: Before final acceptance, the agency inspector, accompanied by the contractor's superintendent or foreman, should make a final inspection of all work.

A.5.2. GRANTING OF EASEMENT TO THE AGENCY

Prior to the agency's signing the improvement plans for the nonpotable water facilities required to serve the area for which user has requested service from the agency, the user should have prepared, processed, granted, recorded, and conveyed to the agency all easements required by the agency for operating, maintaining, modifying or replacing the facilities. All easements should be recorded with the local county recorder.

A.5.3. DEDICATION OF FACILITIES TO AGENCY

Upon completion and final inspection of all work, the user should file a request for dedication to and formal acceptance of the facilities by the agency. The user should also furnish the agency a report of actual costs of said facilities, a proper bill of sale and record drawings of the facilities. Upon said acceptance, the agency should give approval for the construction of the nonpotable water facilities.

A.5.4. GUARANTEES

The user should be responsible for any and all repairs and replacement to agency facilities for a period of one year from the date of acceptance without expense whatsoever to the agency. In the event the user fails to comply with the aforementioned conditions, the agency is authorized to proceed to have the defects repaired and made good at the expense of the user who should pay the cost and charges including attorney fees and other incidental costs involved thereof, immediately upon demand.

A.5.5. ISSUING OF USER PERMIT (SERVICE AGREEMENT)

The user permit issued by the agency to the user should constitute a legally binding service agreement between the two parties. The user permit should incorporate these guidelines and any additional requirements prescribed by the agency to ensure continued operation of the nonpotable water system or to protect the pubic health. The user permit should be issued only upon confirmation by the regulatory agencies. The agency should assign an accounting-number to each permit issued.

A.5.6. ESTABLISHING SERVICE CONNECTIONS

Following the completion of construction and/or installation of the nonpotable water facilities and the submittal and approval of record documents, if required, the user should request the agency to install the service connection, accompanied by all requisite fees for installation and connection.

A.5.7. SERVICE START UP

Following final acceptance of the project by the agency, the user should request service start-up. The agency, upon receipt of such request, should apprise the regulatory agencies of the intent to begin service, set the meter, turn on the service, and then confirm such start-up to the regulatory agencies.

APPENDIX B

INSTITUTIONAL ARRANGEMENTS

CALIFORNIA

B.1 OVERVIEW

Ongoing water reclamation and reuse in California has been implemented with relative ease from an institutional standpoint. As the quantity of nonpotable water use increases together with new and emerging applications, institutional implementation of water reuse projects will also become more challenging. The purpose of this Appendix is to generally outline the major potential institutional issues that may need to be investigated and resolved prior to completing a particular nonpotable water program. It is not intended to present solutions but rather is a document to provoke thought. The Appendix includes discussion of contractual requirements, potable water backup systems, water rights, financing sources, agency communications and needs, paralleling issue, and regulatory policy references.

B.2 CONTRACTUAL REQUIREMENTS

A key factor in implementing a water reuse program is the successful negotiation of an acceptable contract for the use of the nonpotable water. Some of the basic points that may be required by supplier and/or user are listed below. The tabulation is not intended to be a required list of items for all agreements, and may not be all-inclusive.

A. Delineation and responsibilities of all parties to the project (i. e. customer, purveyor, system operator, sanitation/reclamation authority, regional funding agency).

B. Description of facilities for delivery and distribution of nonpotable water (including on-site facilities as required, and ownership).

C. Quantity of nonpotable water to be purchased; including maximum/minimum rates, backup supply rates, project entitlements,

D. Quality of water, including numerical objectives, provisions for variation, regulatory compliance.

E. Operating obligations of parties,

F. Pricing policy, including discount rates to provide incentives, adjustments during contract duration, auditing provisions, impact of potential grants/loans, provisions for avoided energy costs.

G. Billing and payment provisions.

H. Limitation of use.

I. Terms and amendments.

J. Limitations on contractual commitments.

K. Indemnification

B.3. POTABLE WATER BACKUP SYSTEMS

Because nonpotable water is distributed for a variety of uses (i.e. recreational lakes, landscape irrigation, etc.) the need for a potable water back-up system should be evaluated on a case by case basis. Two general scenarios provide a beginning point for determining the need and extent of domestic water backup supplies.

In cases where nonpotable water is being used for fire protection, such as in remote areas where an adequate supply of potable water is not available for drinking and fire flow, or where high volume industrial users are using nonpotable water for process water a back-up system with a short response time should be considered. Under these circumstances hydraulic controls should be included in the system to allow for immediate switching over to potable water in the event of an outage. However, consideration should be given to health department requirements which prohibit converting nonpotable water piping to potable water without special pipeline connection requirements.

In situations where on-potable water is being used for agricultural or landscape uses where outages beyond three days would cause serious plant damage, provisions to allow for conversion should be included. Under this emergency scenario, provisions in the design of the potable and nonpotable distribution systems should be included to allow for a conversion within the three day window. An example would be installing a pair of tee connections between the two pipelines which could be exposed and connection by means of a reduced pressure principle device, or through an air gap into a standpipe.

B.4. WATER RIGHTS

In the planning of a nonpotable water system, water rights issues may need to be addressed. When the producer of nonpotable water is not the same entity as the distributor of potable domestic water, the issue as to who should distribute the nonpotable water should be negotiated. Resolution of this issue may best be addressed in a memorandum of agreement or contract.

Such an agreement could also address other topics such as: a) transfer of rights between public authorities; b) rights to downstream diversion of nonpotable water discharge to a watercourse; and c) nonpotable water producer rights until discharged or "abandoned".

B.5. FINANCING SOURCES

Sources for financing nonpotable water projects can be generally divided into two categories, financing for retrofit programs, and financing for new projects.

B.5.1. Local Projects Funding Program - Because retrofitting existing potable water systems with nonpotable water is considered a 'conservation' measure, these projects can seek funding from a variety of State and Federal water conservation grants. The Metropolitan Water District through its "Local Projects" program will often participate in the cost of retrofit projects if it can be confirmed that these projects will reduce the use of domestic water. An additional source of revenue for financing retrofit projects could be obtained by delaying the changeover from domestic water to nonpotable water rates for a fixed period of time. This source of funding does not result in the direct payment of funds, but rather through avoided costs for purchasing treated water, or other treatment costs.

Additional information on local projects program financing can be obtained from the following:

Local Projects Program
Metropolitan Water District of Southern California
Post Office Box 54153
Los Angeles, CA 90054

B.5.2. State Funding Sources - In addition to the previously mentioned State and Federal Grant funds which may be available for new projects as well, the cost to fund new projects can be obtained through user fees, connection/capacity charges, bond funds, and/or State loans. The State Water Resources Control Board implemented the Water Reclamation Loan Program established under the Clean Water Bond Laws of 1984 and 1988. Loans can be made for approved projects for up to 20 years at an interest rate equal to one-half of the rate paid by the State on preceding general obligation bonds.

Additional information on nonpotable water project financing can be obtained from the following sources:

Office of Water Recycling
State Water Resources Control Board
P.O. Box 944212
Sacramento, CA 94244-2120

B.6. AGENCY COMMUNICATIONS AND NEEDS

Implementation of a nonpotable water project can involve numerous agencies and/or entities to fulfill particular project responsibilities. The interrelationship of such entities in conceptually depicted on Figure C-1. Communications among involved agencies during the project planning process are vital to its success. Inter-agency memorandums-of-understanding (MOU) or memorandums-of-agreement (MOA) are helpful to formally define each agency's role, rights and responsibilities in project execution.

An MOU among the State Water Resources Control Board, California Department of Health Services and the California Department of Water Resources is currently being promulgated to guide the regulatory implementation of nonpotable water projects. Issues on such projects can also involve various departments within a municipality; therefore, inter-department communications are also suggested. A municipal Fire Department should be consulted whenever nonpotable water is to be proposed for fire protection purposes or other uses involving fire hydrants.

It may be necessary to formulate a new public entity (i. e. joint powers agency, community services district) to effectively implement a nonpotable water project. Legal advice should be obtained in these instances, and also regarding other project institutional needs.

B.7. PARALLELING ISSUE

It has been claimed by certain private water purveyors that distribution of nonpotable water constitutes a duplication of service under Sections 1501 through 1506 of the Public Utility

07893

085490

Code. Under these sections of the Codes, an entity providing water service to an area is due fair compensation when another entity encroaches on the original utilities service territory. The service provided by the second entity must be the same type of service the original entity provided.

The value of compensation in this type of situation could be determined as the value of facilities rendered useless, or reduced in value by loss of earnings resulting from loss of market. However, nonpotable water projects implemented in a water-short area may result in a positive off-setting benefit to the private water purveyor. In water reuse applications involving potential duplication of service, communications should lead to a project of mutual benefit.

B.8. REGULATORY POLICY REFERENCES

The following is a partial list of current references on regulatory policies regarding nonpotable water projects:

A. California Code Of Regulations, Title 22, Division 4, Chapter 3, "Wastewater Reclamation Criteria".

B. California Department Of Health Services - Environmental Management Branch: "Guidelines For Use Of Reclaimed Water".

C. California Department Of Health Services - Environmental Management Branch; "Guideline For The Preparation Of An Engineering Report On The Production, Distribution, And Use Of Reclaimed Water".

APPENDIX C

INSTITUTIONAL ARRANGEMENTS

NEVADA

C.1. OVERVIEW

Water reclamation, reuse and the use of raw water is on the increase in Nevada due to constraints on the drinking water supply. As the quantity of nonpotable water use increases together with new and emerging applications, institutional implementation of water reuse projects will also become more challenging. The purpose of Appendix C is to generally outline the major potential institutional issues that may need to be investigated and resolved prior to completing a particular nonpotable water program. It is not intended to present solutions but rather to provoke thought. Appendix C includes a discussion of the following topics:

a. Contractual Requirements
b. Potable Water Backup Systems
c. Water Rights
d. Financing Sources
e. Agency includes and Needs
f. Regulatory Policy References
g. Design References

C.2. CONTRACTUAL REQUIREMENTS

Most of the potable water used in Southern Nevada is from the Colorado River. The amount of Colorado River water available is based on consumptive use, which is defined as diversions less return flows. After the water is used and treated it becomes available for reuse as nonpotable water. The reuse reduces the returned flow to the river and decreases the diversion capability by the amount of the reuse. If the reuse substitutes for a use that would otherwise be met with potable water there is no loss in total supply.

A key factor in implementing a water reuse program is the successful negotiation of an acceptable contract for the use of the nonpotable water. Some of the basic points that may be required by supplier and/or user are listed below. The tabulation is not intended to be a required list of items for all agreements, and may not be all-inclusive.

A. Delineation and responsibilities of all parties to the project (i. e. customer, purveyor, system operator, sanitation/reclamation authority, regional funding agency).

B. Description of facilities for delivery and distribution of nonpotable water (including on-site facilities as required, and ownership).

C. Quantity of nonpotable water to be purchased; including maximum/minimum rates, backup supply rates, project entitlements,

D. Quality of water, including numerical objectives, provisions for variation, regulatory compliance.

E. Operating obligations of parties,

F. Pricing policy, including discount rates to provide incentives, adjustments during contract duration, auditing provisions, impact of potential grants/loans, provisions for avoided energy costs.

G. Billing and payment provisions.

H. Limitation of use.

I. Terms and amendments.

J. Limitations on contractual commitments.

K. Indemnification

L. Conservation incentives

M. Seasonal requirements

C.3. POTABLE WATER BACKUP SYSTEMS

Because nonpotable water is distributed for a variety of uses (i.e. recreational lakes, landscape irrigation, etc.) the need for a potable water back-up system should be evaluated on a case by case basis. Two general scenarios provide a beginning point for determining the need and extent of domestic water backup supplies.

In cases where nonpotable water is being used for fire protection, such as in remote areas where an adequate supply of potable water is not available for drinking and fire flow, or where high volume industrial users are using nonpotable water for process water a back-up system with a short response time should be considered. Under these circumstances hydraulic controls should be included in the system to allow for immediate switching over to potable water in the event of an outage. However, consideration should be given to health department requirements which prohibit converting nonpotable water piping to potable water without special pipeline connection requirements.

In situations where non-potable water is being used for agricultural or landscape uses where outages beyond three days would cause serious plant damage, provisions to allow for conversion should be included. Under this emergency scenario, provisions in the design of the potable and non-potable distribution systems should be included to allow for a conversion within the three day window. An example would be a potable water connection to a non-potable water reservoir with a suitable air gap.

C.4. WATER RIGHTS

In the planning of a nonpotable water system, water rights issues may need to be addressed. When the producer of nonpotable water is not the same entity as the distributor of potable domestic water, the issue as to whom should distribute the nonpotable water should be negotiated. Resolution of this issue may best be addressed in a memorandum of agreement or contract.

Such an agreement should also address other topics such as: a) transfer of rights between public authorities; and b) rights to downstream diversion of nonpotable water discharge to a water-course.

In the State of Nevada, all wastewater effluent is a water of the State and a permit must be obtained to place this resource into use. Under state law the owner of the treatment works must obtain the primary permit for the storage of water and a secondary permit must be obtained by the user.

Additional information on water rights for nonpotable water use can be obtained from the following sources:

1) Department of Conservation and Natural Resources
Division of Water Resources
State Engineers Office
123 W. Nye Lane
Carson City, Nevada 89710

2) Nevada Revised Statutes, Chapter 533

C.5. FINANCING SOURCES

Financing for nonpotable water projects may be available through the State Revolving Loan Fund. Information on nonpotable water project financing can be obtained from:

Department of Conservation and Natural Resources
Division of Environmental Protection
Bureau of Wastewater Treatment Services
123 W. Nye Lane
Carson City, Nevada 89710

C.6. AGENCY COMMUNICATIONS AND NEEDS

Implementation of a nonpotable water project can involve numerous agencies and/or entities to fulfill particular project responsibilities. The interrelationship of such entities is conceptually depicted on Figure C-1. Communications among involved agencies during the project planning process are vital to its success.

It is the policy of the Nevada Division of Environmental Protection (NDEP) to oversee and regulate the distribution of reclaimed wastewater and the regulatory agency responsible for distribution of raw water systems is the Consumer Health Protection Services.

An Effluent Management Plan must be submitted to the NDEP for review and approval before any reclaimed wastewater use may begin. It is the future goal of the NDEP to permit all treatment works which use, store or transfer reclaimed wastewater.

Issues on nonpotable water projects can also involve various departments within a municipality; therefore, inter-department communications are also suggested. A municipal Fire Department should be consulted whenever nonpotable water is to be proposed for fire protection purposes or other uses involving fire hydrants.

State Regulatory Agencies with jurisdiction over nonpotable water reuse include:

1) Nevada Division of Environmental Protection
   Bureau of Wastewater Treatment Services
   123 W. Nye Lane
   Carson City, Nevada 89710

2) Consumer Health Protection Services
   Health Division
   Department of Human Resources
   505 East King
   Carson City, Nevada 89710

C.7. REGULATORY POLICY REFERENCES

The following is a partial list of current references on regulatory policies regarding nonpotable water projects:

1. Nevada Division of Environmental Protection: "GUIDELINES FOR WASTEWATER TREAT MENT PLANT EFFLUENT REUSE", Final Draft - April 11, 1990.

2. Draft Amendment to the Nevada Administrative Code 445.1555 "Reuse of Effluent by Irrigation".

3. Nevada Department of Environmental Protection; Memorandum on Requirements for Effluent Management Plan, dated March 21, 1991.

4. Nevada Administrative Code 445

5. Nevada Revised Statute 445

C.8. DESIGN REFERENCES

In addition to design criteria and details which may be applicable with the local agency, the following reference materials should be used as design references:

1. Water Pollution Control Federation Manuals of Practice.
2. Recommended Standards for Sewage Works (Ten State Standards).
3. Nevada Administrative Code 445.180 Design and Construction of Treatment Works, and Nevada Administrative Code 445 Public Water System Construction.
4. U.S. Environmental Protection Agency Technology Transfer Manuals.
5. AWWA Standards.
6. Specifications for Public Works Construction.

APPENDIX D

OTHER USES FOR NONPOTABLE WATER

This section deals with nonpotable water uses which are currently under development, or uses which are currently in use in limited situations. While these uses are currently not universally approved, or a part of every nonpotable system, they constitute applications which are being considered for full or increased implementation, and should be considered when performing planning and evaluation of nonpotable water distribution systems.

D.1. COOLING TOWER SUPPLY WATER

In industrial applications cooling towers typically rely on domestic water supplies to provide make-up water. This application requires a continuous supply of water, and after use either discharges that water in the form of steam, or backwashes the cooling system into the sanitary sewer system, or other approved means. Since this water is not consumed by people at any point in its use, reclaimed water or other suitable nonpotable water should be considered for this application. Several communities have existing applications of this type, specifically Glendale, CA, and Burbank, CA. At the Chevron refinery in Oakland, CA reclaimed water is now proposed to be used in large industrial cooling tower applications. Because this use of nonpotable water is not specifically weather, or seasonally dependent, it provides a continuous year round market for reclaimed water.

D.2. COMMERCIAL/INDUSTRIAL BUILDING INTERIOR USE

Evaluations of water use patterns in commercial office buildings has indicated that an estimated 70 to 80% of the domestic water used by these facilities is used for flushing toilets, urinals, and priming floor drain trap primers. Several projects are currently underway to use reclaimed water for these uses. Orange County Water District, Fountain Valley, CA, and the Las Virgenes Water District, Calabasas, CA are currently constructing two story administrative office buildings with dual plumbing systems. The Irvine Ranch Water District, Irvine, CA has undertaken an even more aggressive program toward implementing this type of use. The Irvine Ranch Water District has facilitated the construction of several high-rise office towers (six floors and higher) with dual plumbing systems for using reclaimed water for flushing toilets, urinals, and priming floor drain trap primers. It is estimated that there will be as many as twenty-four such buildings prior to ultimate buildout.

All of these applications share several common features.

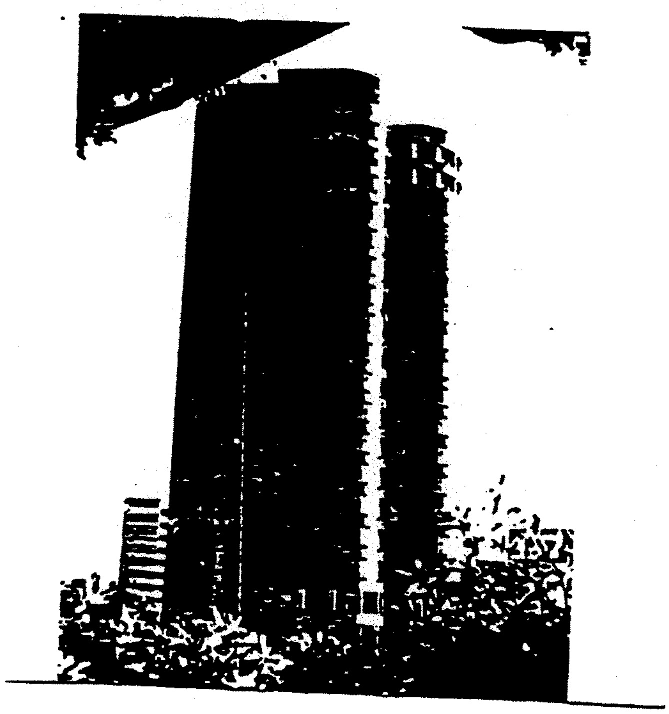
A. All piping within the buildings is copper piping installed in accordance with the requirements of the Uniform Plumbing Code.

B. All reclaimed water piping is wrapped with reclaimed water warning tape, which is colored purple, and imprinted with warning statements.

C. All reclaimed water system control valves are locking lever handle ball valves. These valves are equipped with locks which are installed after the system is checked for cross-connections, and placed into service, with local and state health department approval.

D. Warning signs are installed in the opening of the valve access panels installed in the wall, a Spanish language version is also installed on the inside of the valve access door. Warning signs are also installed in the equipment rooms to notify maintenance personnel that the equipment is handling reclaimed water and certain safety precautions should be followed.

E. An interior separation is installed inside the wall to make sure that the reclaimed water and domestic water pipes are shielded from each other, and to further mitigate potential inadvertent cross connections.



F. Signs are installed in the bathrooms indicating to the users that the facility is equipped with reclaimed water for flushing toilets and urinals as a water conservation measure.

G. In addition to the various physical features of this system, annual testing procedures, and a comprehensive management plan are put into place.

The use of reclaimed water for flushing toilets and urinals, and priming floor drain traps in commercial buildings could provide significant water savings, but will require extensive coordination between state and local health agencies, cognizant building authorities, local builders, engineers, affected trade unions, and Regional Water Quality Control Board. While these are specialized applications within an overall water reclamation system, they should be evaluated as part of the system planning, to determine the extent to which these applications are feasible for the particular reclamation agency.

D.3. FIRE FIGHTING

Since fire fighting water supplies are typically considered stand-by capacity because the use of this capacity is limited to situations where there is a fire, many agencies have begun evaluating the feasibility of shifting this load to the nonpotable water supply system. This use has the advantage of shifting the fire flow demand to the nonpotable system, thus reducing the size of the domestic water distribution pipelines, pump stations, and storage reservoirs. However users who have not provided for this demand on the nonpotable system may have to duplicate many of the domestic water distribution system components. This application of nonpotable water should be pursued in areas where the cost of expanding domestic water supplies is prohibitive based on the potential domestic water use such as rural areas, areas on the outskirts of development, or where a readily available source of nonpotable water exists.

D.4. LARGE RESIDENTIAL ESTATES

Although the use of nonpotable water for irrigating the landscaping around the average single family dwelling is not included in these guidelines, there is a size of lot which may lend itself to this application. Single family dwellings erected on large lots (one acre or more) provide a sufficiently large point demand to warrant consideration for reclaimed or nonpotable water irrigation. These large estate lots, or "ranchettes", are large enough to typically employ a landscape maintenance service, include an extensive landscape irrigation system, and yield a water demand commensurate with the size of the system. Several agencies in California are working with the state and local health officials to develop standards for this type of application. As a result this type of non-traditional use of nonpotable water should be evaluated in reclamation planning.

Guidelines for Use of Reclaimed Water

07910

085507

June 10, 1988

State of California
Department of Health Services
Environmental Management Branch
GUIDELINES FOR USE OF RECLAIMED WATER

I. General

A. Reclaimed water shall meet the Regional Water Quality Control Board (RWQCB) requirements and the requirements specified in the "Wastewater Reclamation Criteria." (Title 22, Div. 4, Section 60301 through 60355). These guidelines apply to those reclaimed water use areas supplied water from sewage treatment plants having reliability features and operational histories meeting the Regional Water Quality Control Board and "Wastewater Reclamation Criteria" requirements. Additional precautions may be required where these conditions are not met.

B. Reclaimed water should be confined to the authorized use area.

1. Direct or windblown spray should be confined to the area designated and approved for reclamation.

2. Precautions should be taken to assure that reclaimed water will not be sprayed on any facility or area not designated for reclamation such as passing vehicles, buildings, domestic water facilities or food handling facilities.

C. Notification should be provided to inform the public that reclaimed wastewater is being used. The notification should include the posting of conspicuous warning signs with proper wording of sufficient size to be clearly read.

D. Public contact with reclaimed water should be minimized except where specifically approved by the health agencies and the Regional Water Quality Control Board.

E. The reclaimed water distribution and transmission system piping should comply with the design requirements contained in the California-Nevada Section AWWA publication "Guidelines for Distribution of Nonpotable Water."

1. All piping, valves and outlets should be marked to differentiate reclaimed water from domestic or other water.

2. All reclaimed water controllers, valves, etc., should be affixed with reclaimed water warning signs.

F. All reclaimed water valves, outlets, quick couplers, and sprinkler heads should be of a type, or secured in a manner that only permits operation by personnel authorized by the user.

G. Use or installation of hose bibbs on any irrigation system presently operating or designated to operate with reclaimed water, regardless of the hose bibb construction or identification, should not be permitted.

H. There should be at least a 10-foot horizontal and 1-foot vertical separation (with the domestic water above the reclaimed water pipeline) between all pipelines transporting reclaimed water and those transporting domestic water.

I. Plans and specifications for the reclaimed and domestic water systems should be submitted to the Sanitary Engineering Branch of the State Department of Health Services and the local health department for review and approval before construction of new reclamation facilities or system conversion.

J. An air-gap separation or reduced pressure principle device shall be provided at all domestic water service connections to reclaimed water use areas. (Title 17, Chapter 5, Section 7604).

K. There shall be no connection between the potable water supply and piping containing reclaimed water. Supplementing reclaimed water with water used for domestic supply shall not be allowed except through an air-gap separation. (Title 17, Chapter 5, Section 7604).

L. Supplementing reclaimed water with water from irrigation or industrial wells should not be allowed except through an air gap or reduced pressure principle device.

M. Drinking water facilities should be protected from direct or windblown reclaimed water spray.

N. Tank trucks and other equipment which are used to distribute reclaimed water should be clearly identified with warning signs.

O. There should be no irrigation or impoundment of reclaimed water within 500 feet of any well used for domestic supply or 100 feet of any irrigation well unless it can be demonstrated that special circumstances justify lesser distances to be acceptable.

P. Adequate measures should be taken to prevent the breeding of insects and other vectors of health significance, and the creation of odors, slimes or unsightly deposits.

Q. A user supervisor should be appointed by the user. The user supervisor should be responsible for installation, operation and maintenance of the reclamation system, prevention of potential hazards, implementing these Guidelines, and coordination with the cross-connection control program of the water purveyor or the local health department.

R. The user should maintain as-built plans of the use area showing all buildings, domestic and reclaimed water facilities, the sewage collection system, etc. Plans should be updated as modifications are made.

S. A contingency plan including notification of the RWQCB and health agencies should be developed outlining the action to be taken in the event effluent quality fails to meet required standards.

T. Inspection, supervision and employee training should be provided by the user to assure proper operation of the reclaimed water system. Records of inspection and training should be maintained by the user.

U. The producer and/or user should submit a monthly report to the State Department of Health Services and the local health agencies containing:

1. The quality and quantity of water reclaimed.

2. The use (the method of irrigation and the crop(s) and area(s) irrigated).

3. The reason for noncompliance with standards, if appropriate and the corrective action taken.

II. <u>Landscape Irrigation</u>

A. At parks, playgrounds, schoolyards, other areas (e.g. golf courses with contiguous residential development) where the public has similar access or exposure, and other areas irrigated with oxidized, coagulated, clarified, filtered, disinfected wastewater having a 7- day median number of coliform organisms not exceeding 2.2/100 ml, and a maximum concentration of coliform organism not exceeding 23/100 ml in any sample:

(The reclaimed water treatment and quality stated above also applies at use areas having adjacent property where the public may be subject to direct or indirect contact with reclaimed water spray for example; golf courses with contiguous residential development).

1. Adequate signs should be posted indicating that reclaimed wastewater is used for irrigation and is not safe for drinking (e.g. ATTENTION: RECLAIMED WASTEWATER - DO NOT DRINK).

B. At golf courses not included in A. above irrigated with oxidized, disinfected wastewater having a 7-day median number of coliform organisms not exceeding 23/100 ml or any two consecutive coliform samples not exceeding 240/100 ml:

1. Irrigation should only be practiced when golfers are not present.

2. Adequate signs should be posted indicating that reclaimed wastewater is used for irrigation and it is not safe for drinking or contact (e.g. ATTENTION: RECLAIMED WASTEWATER AVOID CONTACT - DO NOT DRINK).

3. Score cards should indicate that reclaimed wastewater is used.

4. Irrigation with reclaimed water should not occur in areas where food is handled or consumed.

5. Irrigation should be controlled to prevent ponding and runoff of reclaimed water unless acceptable to the Regulatory Agency.

C. At cemeteries irrigated with oxidized, disinfected wastewater having a 7-day median number of coliform organisms not exceeding 23/100 ml or any two consecutive coliform samples not exceeding 240/100 ml:

1. Irrigation should be scheduled for times the public is not present.

2. Adequate signs should be posted indicating that reclaimed wastewater is used for irrigation and it is not safe for drinking or contact (e.g. ATTENTION: RECLAIMED WASTEWATER AVOID CONTACT - DO NOT DRINK).

3. Potable water should be supplied for flower containers.

4. Irrigation should be controlled to prevent ponding and runoff of reclaimed water unless acceptable to the Regulatory Agency.

D. Highway landscape and other landscaped areas irrigated with oxidized, disinfected wastewater having a 7-day median number of coliform organisms not exceeding 23/100 ml or any two consecutive coliform samples not exceeding 240/100 ml:

1. Signs should be posted along the perimeter at points of access to the use area indicating that reclaimed wastewater is used for irrigation and it is not safe for drinking or contact (e.g. ATTENTION: RECLAIMED WASTEWATER AVOID CONTACT - DO NOT DRINK).

2. Irrigation should be controlled to prevent ponding and runoff of reclaimed water unless acceptable to the Regulatory Agency.

III. Impoundments

A. Nonrestricted recreational impoundments containing oxidized, coagulated, clarified, filtered, disinfected wastewater having a 7-day median number of coliform organisms not exceeding 2.2/100 ml and a maximum concentration of coliform organisms not exceeding 23/100 ml in more than one sample in a 30-day period:

1. Impoundments should have perimeter signs indicating that the wastewater stored is not safe for drinking (e.g. ATTENTION: RECLAIMED WASTEWATER - DO NOT DRINK).

2. Runoff should be prevented from entering the pond unless the impoundment is sized to accept the runoff without discharge or an NPDES permit has been issued for the discharge.

3. There should be no discharge of reclaimed water to any pond with less than one foot of freeboard unless discharge from the pond is allowed by NPDES permit.

B. Restricted recreational impoundments containing oxidized, disinfected wastewater having a 7-day median number of coliform organisms not exceeding 2.2/100 ml:

1. Impoundments should have perimeter signs indicating that the wastewater stored is not safe for drinking or body contact (e.g. ATTENTION: RECLAIMED WASTEWATER AVOID CONTACT - DO NOT DRINK).

2. Runoff should be prevented from entering the pond unless the impoundment is sized to accept the runoff without discharge or an NPDES permit has been issued for the discharge.

3. There should be no discharge of reclaimed water to any pond with less than one foot of freeboard unless discharge from the pond is allowed by NPDES permit.

C. Landscape impoundments containing oxidized, disinfected wastewater having a 7-day median number of coliform organisms not exceeding 23/100 ml:

1. Impoundments should have perimeter signs indicating that the wastewater stored is not safe for drinking or body contact(e.g. ATTENTION: RECLAIMED WASTEWATER AVOID CONTACT - DO NOT DRINK).

2. Runoff should be prevented from entering the pond unless the impoundment is sized to accept the runoff without discharge or an NPDES permit has been issued for the discharge.

3. There should be no discharge of reclaimed water to any pond with less than one foot of freeboard unless discharge from the pond is allowed by NPDES permit.

IV. Agricultural Reuse Area Guidelines

A. At areas irrigated with undisinfected primary or undisinfected secondary effluent:

1. Warning signs reading "SEWAGE DISPOSAL AREA - KEEP OUT" should be posted at least every 500 feet with a minimum of one sign at each corner and one at each access road.

2. Fencing or other barriers should be installed where needed to restrict public access.

3. The perimeter of the disposal area should be graded to prevent ponding along public roads or other public areas.

4. Setbacks

a. Surface Irrigation - setbacks should be established where needed to restrict public contact.

b. Spray Irrigation - there should be no irrigation within 500 feet of the authorized spray boundary. A setback of less than 500 feet may be approved if warranted by the use area design. Some of the use area characteristics to be taken into account are: wind velocity and direction, topography, sprinkler characteristics and controls.

B. At areas irrigated with oxidized, disinfected, wastewater having a 7-day median number of coliform organisms not exceeding 23/100 ml:

1. Perimeter warning signs indicating that the reclaimed wastewater is not safe for drinking or contact (e.g. WARNING: RECLAIMED WASTEWATER AVOID CONTACT - DO NOT DRINK) should be posted at least every 500 feet with a minimum of one sign at each corner and one at each access road.

2. Fencing should be installed where needed to restrict public access.

3. The perimeter of the disposal area should be graded to prevent ponding along public roads or other public areas.

4. Setbacks

a. Surface Irrigation - Setbacks should be established where needed to restrict public contact.

b. Spray Irrigation - The amount of setback is to be determined by the use of the adjoining property.

C. At areas irrigated with oxidized, disinfected wastewater having a 7-day median number of coliform organisms not exceeding 2.2/100 ml:

1. Warning signs indicating that the reclaimed wastewater is not safe for drinking or contact (e.g. WARNING: RECLAIMED WASTEWATER AVOID CONTACT - DO NOT DRINK) should be posted with a minimum of one sign at each corner and one at each access road.

2. Fencing or other barriers should be installed where needed to restrict public access.

3. The perimeter of the disposal area should be graded to prevent ponding along public roads or other public areas.

4. Setbacks

a. Surface Irrigation - Setbacks should be established where needed to restrict public contact.

b. Spray Irrigation - The amount of setback is to be determined by the use of the adjoining property.

D. At areas irrigated with oxidized, disinfected, coagulated, clarified, filtered, disinfected wastewater having a 7-day median number of coliform organisms not exceeding 2.2/100 ml:

a. Warning signs indicating that the reclaimed wastewater is unsafe to drink (e.g. WARNING: RECLAIMED WASTEWATER - DO NOT DRINK) should be posted every 500 feet with a minimum of one sign at each corner and one at each access road.

E. The following table indicates the minimum degree of treatment for the specific types of crops and methods of application:

TREATMENT GUIDELINES FOR AGRICULTURAL USE OF RECLAIMED WATER

MINIMUM DEGREE OF TREATMENT FOR TYPE OF CROP AND METHOD OF APPLICATION

TYPE OF CROP	PRIMARY EFFLUENT	OXIDIZED, DISINFECTED TO 23 mpn/100 ml	OXIDIZED, DISINFECTED TO 2.2 mpn/100 ml	OXIDIZED, COAGULATED CLARIFIED, FILTERED, DISINFECTED TO 2.2 mpn/100 ml

* - Not allowed

1. Not acceptable for root crops or crops where edible parts touch the ground.

2. Processed food crops must undergo extensive commercial, physical, or chemical processing sufficient to destroy pathogenic agents. Processing does not include washing, pickling, fermenting, or milling.

3. Edible portion of plant does not contact the ground.

4. Not for human ingestion.

5. No spraying within 30 days of fruit formation.

07919

085516

V. Guidelines for Worker Protection

A. Workers should be informed of the potential health hazards involved with contact or ingestion of reclaimed water, and should be educated regarding proper hygienic procedures to protect themselves and their families.

B. Precautionary measures should be taken to minimize worker contact with reclaimed water.

1. Workers should not be subjected to reclaimed water sprays.

2. Workers should be provided with protective clothing when there will be more than casual contact with the reclaimed water.

3. Where oxidized, coagulated, clarified, filtered, disinfected wastewater is used, less stringent precautions may be allowed.

C. Safe drinking water should be supplied for workers. Where bottled water is provided, the water should be in contamination-proof containers and protected from reclaimed water and dust.

D. Handwashing facilities should be provided.

E. Precautions should be taken to avoid contamination of food taken into reclaimed water use areas. Food should not be taken into areas still wet with reclaimed water.

F. Workers should be notified that reclaimed water is in use. Notification should include the posting of conspicuous warning signs with proper wording of sufficient size to be clearly read.

In those locations where English is not the primary language of the workers, the signs should be in the appropriate language as well as English.

G. An adequate first aid kit should be available on location.

Guidelines for the Use of Reclaimed Water for Construction Purposes

07921

085518

June 10, 1988

State of California
Department of Health Services
Environmental Management Branch
GUIDELINES FOR THE USE OF RECLAIMED WATER
FOR
CONSTRUCTION PURPOSES

Controls at Treatment Plant

1. Reclaimed water used for soil compaction, dust control, and other construction purposes where the workers or the public have similar access or exposure shall be at all times an adequately disinfected, oxidized wastewater. The wastewater shall be considered adequately disinfected if the median number of coliform organisms in the effluent does not exceed 23 per 100 milliliters, as determined from the bacteriological results of the last seven days for which analyses have been completed, and the number of coliform organisms does not exceed 240 per 100 milliliters in any two consecutive samples.

2. Unless otherwise specified, all applicable sections of the Wastewater Reclamation Criteria must be complied with, including the design, operational, and reliability requirements.

   a. Exceptions to specified sections of the criteria will be considered by the Department of Health Services on an individual case basis.

Controls on Hauling and Use

1. Use sites must be approved by the Regional Water Quality Control Board and the State and local health departments.

2. Truck drivers should be instructed as to the requirements contained herein and the potential health hazards involved with the reuse of wastewater.

3. Tank trucks and other equipment which contain or come in contact with reclaimed water should be clearly identified with warning signs.

4. Tank trucks used for reclaimed water should be thoroughly cleaned of septage or other contaminants prior to use.

5. Use of reclaimed water should not create any odor or other nuisance.

6. Reclaimed water should be confined to the authorized use area.

   a. Ponding or runoff of reclaimed water should not occur.
   b. Aerosol formation during uses involving spraying should be minimized.

7. Reclaimed water should be applied so as to prevent public or employee contact with the water.

8. Reclaimed water must not be introduced into any permanent piping system and no connection shall be made between the tank truck and any part of a domestic water system.

9. Tank trucks should be cleaned and disinfected after the project is completed.

10. Tank trucks used to transport reclaimed water shall not be used to carry domestic water.

A GUIDE TO SAFE RECLAIMED WASTEWATER USE, PIPELINE CONSTRUCTION AND INSTALLATION

INTRODUCTION: As a result of increasing availability of reclaimed wastewater and the consequent need or desire for the transmission and use thereof, this Department has found it necessary to develop the following guidelines for reclaimed wastewater pipeline construction, installation and safe reclaimed wastewater use for the protection of domestic water supplies and public health.

1. Reclaimed wastewater shall meet requirements specified in "Wastewater Reclamation Criteria": Title 22, Division 4, Chapter 3, Section 60301 through 60355 of the California Code of Regulations and regulations and guidelines of the regulatory agencies.

2. Reclaimed wastewater use shall be compatible with State Department of Health Services and Regional Water Quality Control Board requirements.

3. Plans and specifications for reclaimed wastewater distribution, use and operational practices shall be submitted for review and approval to the County of Los Angeles Department of Health Services prior to implementation.

4. Prior to commencing construction the Contractor shall contact the Los Angeles County Department of Health Services to arrange for inspection of all on-site reclaimed and potable water work. No excavation or open trench may be backfilled without first securing Health Department approval. If any piping, reclaimed or potable, is installed prior to plan check approval and/or inspection, all or any portion of the system may be required to be exposed and corrected as necessary.

5. **SEPARATION** - In order to minimize construction accidents resulting in pipeline breaks, infiltration of wastewater from leaking wastewater lines into domestic water lines, or accidental cross-connections between reclaimed wastewater and potable water systems, maximum attainable separation of reclaimed wastewater lines and potable water lines shall be practiced.

   a. <u>Parallel construction:</u> there shall be at least a ten foot (10') separation, all distances measured from pipeline outside diameter.

07925

085522

DRAFT

b. Cross-Over construction: As perpendicular as possible; one foot (1') separation, with potable above reclaimed; full pipe length centered over crossing.

c. Alternate Cross-Over construction (distance not maintained): Either the potable or reclaimed water lines may be sleeved with the same class piping for one full pipe length (minimum ten feet) centered over the cross-over.

d. The reclaimed wastewater system shall be constructed in conformance with potable water system construction standards and in accordance with all other governing codes, rules and regulations.

e. Unused or abandoned potable water lines are to be severed as close to water mains as practical, capped and a ten-foot section of abandoned line removed and cemented under Health Department supervision.

Existing On-site piping - To the extent feasible, maximum separation of reclaimed wastewater and potable water lines shall be practiced upon system addition or modification.

6. IDENTIFICATION: - All reclaimed wastewater lines (pressure/non-pressure), valve boxes, hydrants and appurtenances shall be identified to clearly distinguish between reclaimed wastewater and potable water systems.

a. **RECLAIMED WASTEWATER** - All buried reclaimed wastewater lines (pressure/non-pressure) shall be identified by continuous lettering on three inch (3") minimum width purple tape with one inch black or white contrasting lettering bearing the continuous wording "Caution Reclaimed Water" permanently affixed at ten foot intervals atop all horizontal piping, laterals and mains. Identification tape shall extend to all valve boxes and/or vaults, exposed piping, hydrants and quick couplers.

The use of purple colored pipe with continuous wording "Caution Reclaimed Water" printed on opposite sides of the pipe is an acceptable alternative to warning tape.

b. **POTABLE WATER** - All potable water lines shall be installed in accordance with the Uniform Plumbing Code and all other governing codes, rules and regulations. Buried potable water lines shall be identified by continuous lettering on three inch (3") minimum width blue tape with one inch

07926

085523

white lettering bearing the continuous wording "Potable Water" permanently affixed at ten foot intervals atop all horizontal piping, laterals and mains. Identification tape shall extend to all valve boxes and/or vaults, exposed piping and hydrants.

DRAFT

Identification tape is not necessary for extruded colored PVC with continuous wording "Potable Water" printed in contrasting lettering on opposite sides of the pipe.

c. Exposed piping, valve boxes, vaults, control valves, quick coupling valves, outlets and related appurtenances shall be color coded and labeled or tagged to differentiate reclaimed wastewater from potable water, ie.,

   i. "Caution Reclaimed Water Do Not Drink" in black or white contrasting lettering on a purple background.

   ii. "Potable Water" in white lettering on a blue background.

Tags shall be identified with the appropriate wording on both sides. Tags identifying reclaimed water shall have the appropriate wording on one side and symbol on the opposite side.

7. Aquifers shall be protected against contamination by reclaimed wastewater via deteriorated or inadequately protected waterwell casings by correcting these physical deficiencies. Reclaimed wastewater shall not be sprayed on well pump installations and appurtenances.

8. An <u>on-site water supervisor</u> having the responsibility for the protection of the potable water system from cross-connections, shall be appointed as provided for under Title 17, Section 7586, California Code of Regulations. The water supervisor shall be responsible for installation, operation, and maintenance of the reclaimed wastewater and potable water systems, prevention of potential hazards, implementing these guidelines and coordination with the cross-connection control program of the water purveyor and this Department. Authorizations for piping changes or additions to either the potable or reclaimed wastewater systems shall be subject to review and approval by the water supervisor. The name and position of this individual shall be reported to the water purveyor and the County of Los Angeles Department of Health Services.

DRAFT

9. As-built plans shall be prepared and updated as necessary by the user showing the location of reclaimed wastewater and potable water system piping.

10. In areas of public access to reclaimed wastewater systems, hose bibbs shall not be permitted in order to prevent the unauthorized use of reclaimed wastewater. Quick-couplers are permissible in lieu of hose bibb outlets and shall only be connected to reclaimed wastewater lines.

    In areas not accessible to the public, hose bibbs may be permitted provided they are properly identified with permanently affixed tags, labels, or plates with the wording "Reclaimed Water - Do Not Drink" in English and symbol.

11. Exposure of drinking fountains and picnic tables to direct reclaimed wastewater spray shall be minimized by a combination of selective location of such equipment and by appropriate irrigation system design.

    a. Reclaimed wastewater spraying shall be done in hours of least public exposure.

    b. Areas where reclaimed wastewater is released, used or impounded shall be posted (e.g., RECLAIMED WATER - DO NOT DRINK), to inform the public that reclaimed water is being used.

    c. Irrigation practice shall be controlled to prevent surface runoff of reclaimed wastewater from lands owned or controlled by the user.

12. **BACKFLOW PROTECTION**

    a. There shall be no interconnection between the Potable Water System and the Reclaimed Water System within the user's premises.

    b. A dye or pressure test must be utilized to confirm the physical separation of the reclaimed and potable water systems. Said testing shall be performed in conjunction with the Water Purveyor and this Department and conducted before the introduction of reclaimed wastewater.

07928

    c. Contact the local water purveyor regarding required backflow protection at the potable water

d. In order to maintain the water quality in a reclaimed wastewater distribution system a backflow prevention device(s) may be required at the reclaimed wastewater meter or at specific on-site locations where said use could degrade the quality of the reclaimed wastewater supply.

OPINION APPROVING WATER MANAGEMENT PROGRAM AND AUTHORIZING SERVICE AREA EXPANSION

TABLE OF CONTENTS

OPINION APPROVING WATER MANAGEMENT PROGRAM AND AUTHORIZING SERVICE AREA EXPANSION

I. Summary

The Commission approves Valencia Water Company's (Valencia) 1999 Water Management Program (WMP) and Advice Letters (ALs) 88 and 90, requesting permission to expand its service area. Approval of these advice letters authorizes Valencia to provide water service to the North Valencia 2, Mountain View, West Creek, and Tesoro del Valle development projects. Upon completion of the projects, Valencia would add a total of approximately 6020 customers to its service area, and the incremental water demand would be 5,011 acre-feet per year (AFY).

The respective Environmental Impact Reports (EIRs) for these four development projects were previously certified either by Los Angeles County or the City of Santa Clarita acting as "lead agency" under the California Environmental Quality Act (CEQA). Along with its Proponents' Environmental Assessment (PEA), as required by Rule 17.1 of the Commission's Rules of Practice and Procedure, Valencia submitted copies of these EIRs, with a motion requesting approval of its ALs 88 and 90 covering the four projects. The Commission staff reviewed these EIRs and concluded that the EIRs were complete and adequate for purposes of the Commission's review.

As a "responsible agency" pursuant to the CEQA Guideline 15096, the Commission has considered the environmental assessments contained in the environmental documents for the four related land development projects that encompass ALs 88 and 90. The Commission concludes that all environmental impacts that may be associated with the extensions of water service proposed by ALs 88 and 90 were within the scope of the environmental impact reviews that were performed in connection with the related land development projects.

The Commission rejects the arguments of Sierra Club and the County of Ventura that the Commission should assume the role of lead agency and issue an EIR on the WMP and all water supplies shown as available in the WMP before it can address ALs 88 and 90.

After review of the WMP in conjunction with ALs 88 and 90, the Commission concludes that the water supplies that the WMP demonstrates to be available provide an ample margin of safety to allow Valencia to serve new customers to the extent contemplated by ALs 88 and 90.

II. Factual Background Regarding Valencia's Water Supplies

Valencia is a Class A water utility offering public utility water service for a mix of residential and commercial land uses in portions of the Santa Clarita Valley of Northern Los Angeles County. It is one of the four retail water purveyors serving the Santa Clarita Valley, the others being Newhall County Water District, Santa Clarita Water Company, and Los Angeles County Waterworks District 36. The Castaic Lake Water Agency (CLWA) performs a wholesale function, contracting for water supplies from the State Water Project (SWP) and potentially other sources, treating those supplies in its Rio Vista and Earl Schmidt Treatment Plants, and delivering them to the four retail purveyors for service to end-use customers. Since CLWA's acquisition of Santa Clarita Water Company in 1999, Valencia is the only one of these entities subject to regulation by the Commission.

The primary source of water supplies for the Santa Clarita Valley historically has been groundwater pumped from the Alluvial Acquifer and the underlying Saugus Formation. Beginning in 1980, CLWA has delivered imported water from the SWP into the Valley, supplementing these groundwater supplies, and more recently CLWA has undertaken plans to deliver highly treated recycled water from existing water reclamation plants operated by the County Sanitation Districts of Los Angeles County.

Valencia's own water system includes 18 wells in the Alluvial Aquifer, five wells in the Saugus Formation, and six connections, called turnouts, to CLWA's system by which Valencia receives SWP water from CLWA. Valencia generally produces water using a mix of about 50% groundwater and 50% imported water, with some variation in the mix depending on peak demands and weather conditions.

The groundwater basin in the Santa Clarita Valley is unadjudicated, meaning that neither Valencia nor the other purveyors have adjudicated water rights that dictate their water supply. The total supply available to all purveyors in the basin and the ability of Valencia to access those supplies determines the amount available to Valencia to meet its long-term supply needs.

III. Procedural Summary

A. Events Before This Proceeding

Until recently, Commission staff regularly approved advice letter filings authorizing Valencia to extend its service area boundaries to encompass new developments upon confirming the adequacy of Valencia's water supply and facilities to meet anticipated demand for service.

Broader issues regarding such authorizations were brought to the Commission's attention by a complaint filed in September 1998 by the Angeles Chapter of the Sierra Club (Sierra Club), which alleged that Valencia and other water retailers had overpumped the Alluvial Aquifer; consequently, the complaint challenged the adequacy of available water supplies to meet the future demand represented by proposed housing developments for which preliminary plans showed Valencia as the likely provider of water services. Sierra Club sought an order from the Commission determining that Valencia had reached the limit of its capacity to supply new customers without harm to current customers. The Commission dismissed the complaint, stating that it would "adjudicate Valencia's capacity to serve additional customers in the proceedings where Valencia seeks authorization to serve those customers." (*Sierra Club v. Valencia Water Company*, Decision (D.) 99-04-061, Conclusion of Law 4.)

Meanwhile, in March and April 1999, Valencia had filed ALs 84 and 85, seeking authority to expand its service area to serve an additional 3,400 homes. Sierra Club protested these advice filings, alleging insufficient supply due to overpumping of groundwater, inadequate SWP supply, and a lack of storage or means of conveyance for imported water. By Resolution W-4154, adopted August 5, 1999, the Commission found, based on staff review, that Valencia's water supply was adequate to serve the additional service territory requested in ALs 84 and 85, and so approved the advice letters. However, the Commission also adopted the staff recommendation that Valencia be ordered to prepare an updated WMP to enable the Commission and all interested parties to evaluate the effects of further expansion of its service area on its water supply.[1]

B. This Proceeding

On December 17, 1999, Valencia responded to Resolution W-4154 by filing its application seeking approval of an updated WMP. Protests to the application were filed by Sierra Club, Santa Clarita Organization for Planning the

[1] Sierra Club's request for rehearing of Resolution W-4154 was denied in D.99-11-032.

Environment (SCOPE), Friends of the Santa Clarita River (Friends of the River), County of Ventura (Ventura), and the Ratepayer Representation Branch of the Commission's Water Division staff (Water Division).[2] A prehearing conference (PHC) was held on February 8, 2000, before Commissioner Josiah Neeper and Administrative Law Judge (ALJ) Bertram Patrick, in Los Angeles, and a Scoping Memo and Ruling of Assigned Commissioner was issued February 18. The Scoping Memo noted agreement among the parties that the issues in this proceeding should include (1) whether Valencia's current and planned water supplies are sufficient to meet future customer needs; and (2) whether the Commission should approve Valencia's updated WMP.

The Scoping Memo noted Sierra Club's and Ventura's (jointly referred to as Protestants) contentions that the proceeding also should consider the total future demand for water in the Santa Clarita Valley and the impact of Valencia's proposed water use on downstream water users. After referencing and quoting at length the Commission's observations in D.99-04-061 about its limited role and authority in water supply planning matters, the Assigned Commissioner concluded that it was "not appropriate to expand the scope of this proceeding to include modeling of basin wide surface/groundwater flows and a comprehensive analysis of water to the entire region water supply, as requested by Ventura," and so ruled that the scope of the proceeding would be limited to the two issues set forth above, and that the reliability of SWP supplies and the availability of groundwater supplies is relevant only to the extent that these

---

[2] Because Sierra Club, SCOPE, and Friends of the River were jointly represented by counsel and have taken common positions throughout the course of this proceeding, they are referenced jointly as "Sierra Club."

affect the supply to Valencia's present and future customers. (Scoping Memo, pp. 5-6.)

On March 20, 2000, Valencia filed AL 88, seeking authority to expand its service area to include portions of two land developments, known as North Valencia Annexation-2 (North Valencia 2) and Mountain View, both generally abutting the northerly boundaries of Valencia's existing service area and together comprising 1,898 dwelling units on 484 acres of mixed use development. On September 19, 2000, Valencia filed AL 90, requesting permission to extend service to two additional land developments, West Creek and Tesoro del Valle, north and west of the North Valencia 2 area and together presenting the potential for adding 4,122 dwelling units into Valencia's service area.

In accordance with the established schedule, the parties proceeded to serve prepared direct and rebuttal testimony in April and May, 2000. Six days of evidentiary hearings were held in Los Angeles during late May and early June, 2000. The schedule for submission of briefs was suspended, however, due to Ventura's motion on May 22, the first day of hearing, asking the Commission to determine that this proceeding involves a "project" under the terms of the CEQA, Public Resources Code § 21000 *et seq.*, and relevant regulations. Sierra Club filed a similar motion on May 30.

In D.00-10-049, the Commission ruled on Sierra Club's and Ventura's motions relating to CEQA. The Commission confirmed its past conclusions that the Commission's role in water use decisions is significantly more limited than that of other state and local agencies, "with a focus upon ensuring that each jurisdictional water utility provides its customers with 'just and reasonable service, …and facilities as are necessary to promote the safety, health, comfort, and convenience of its patrons, employees, and the public.'" (D.00-10-049, mimeo., at 8.)

The Commission recounted the course of events leading to Valencia's filing of the present application, noting that the filing of an updated WMP apart from a general rate case "is unusual, but was adopted to provide a forum to review the issues raised earlier by Sierra Club." (*Id.* at 7.) The Commission also discussed the pending ALs 88 and 90, noting that "while they have not been formally consolidated with the WMP, and remain separate filings, they are related, and both ALs 88 and 90 are dependent upon the WMP." (*Id.* at 8.) Specifically, "the Commission's stated intent is that approval of advice letters such as AL 88 and AL 90 can only occur after Commission approval of Valencia's WMP." (*Id.*)

On the question whether Valencia's application for approval of the WMP constitutes a "project" under CEQA, the Commission concluded that "CEQA is applicable to the present WMP together with ALs 88 and 90." (*Id.* at 22, 24 (Conclusion of Law 1).) Noting that local agencies had prepared EIRs for each of the development projects to which ALs 88 and 90 relate, the Commission saw no reason to duplicate CEQA reviews already conducted by other agencies. Accordingly, the Commission ordered Valencia to file a Proponent's Environmental Assessment (PEA) addressing "the service area expansions proposed in ALs 88 and 90 and reflected in the WMP," while also submitting copies of any EIRs relating to the ALs, along with evidence of any final local agency actions relating to those EIRs. (*Id.*, Ordering Paragraph 1.)

On November 13, 2000, Valencia made the required submissions, formally filing its PEA. On the same day, following the guidance of Commission staff, Valencia also filed a Motion for Review and Approval of Tariff Changes

Proposed by ALs 88 and 90, asking that the Commission consider granting approval of the ALs in this proceeding, concurrently with its action on the WMP.

On November 18, 2000, a PHC was held to discuss the scope of CEQA review and to establish procedures for that and related purposes. In PHC statements and a reply to Valencia's motion, Sierra Club and Ventura contended that environmental review of the WMP should not be limited to the incremental increases in demand associated with ALs 88 and 90, and that the WMP must be approved *before* the Commission can address the advice letters. Valencia responded that both CEQA and D.00-10-049 mandate that ALs 88 and 90 be considered concurrently with the WMP, because D.00-10-049 essentially held that the WMP and the advice letters are part of the same project and, for CEQA purposes, all elements of a project must be considered together.

In a ruling issued December 21, 2000, the Assigned Commissioner confirmed the Commission's intent "to consider Advice Letters 88 and 90 in conjunction with the WMP." Noting that a WMP, in isolation, is simply a planning document that does not typically provide a water utility any entitlement for future expansion of its service area, the Assigned Commissioner recalled the discussion in D.00-10-049 explaining the facts that made this case "somewhat unique." After extensively quoting from that decision, the Assigned Commissioner concluded that all responsible interests would be served by having the Commission "conduct its CEQA review and its substantive consideration of both the WMP and ALs 88 and 90 through a concurrent process, culminating in a single Commission decision addressing the relevant issues … within the 18-month time frame mandated by statute." The Assigned Commissioner specifically ruled that the "project" for CEQA review purposes was the WMP "in conjunction with ALs 88 and 90," and instructed the ALJ to proceed with review of the PEA consistent with D.00-10-049.

On May 11, 2001, the ALJ issued a ruling noting that Commission staff had reviewed the documents filed by Valencia comprising its PEA and that staff found the PEA to be complete for CEQA review purposes for each of the development projects that Valencia now seeks Commission authority to serve. The ALJ set further days of hearing on the advice letters and also to allow updating of the record related to the WMP, if necessary.

Pursuant to the ALJ's ruling, the parties served further prepared testimony and held two more days of evidentiary hearing in Los Angeles on June 12-13, 2001. Opening and reply briefs were filed by Sierra Club, Valencia, and Ventura, and this proceeding was submitted for decision on August 27, 2001.

IV. The Proper Role of the Commission Under CEQA

The real question raised by Protestants is whether Valencia's application requesting Commission approval of the WMP (and associated ALs) reveals a regulatory gap in regard to the long-term water supply planning in the Santa Clarita Valley, and if so, is the Commission the agency to fill that gap? Protestants would say "yes," based on their perception that (1) environmental review conducted locally is incomplete, and (2) the WMP is a planning document requiring at least a program EIR. Valencia says "no" to these questions, based on its belief that (1) environmental review (including cumulative impacts analysis) was conducted by the local permitting authorities, and (2) the build-out analysis performed already by CLWA and Los Angeles County, constitute the long-term supply planning for CEQA purposes, <u>not</u> the WMP.

For the reasons set forth below, we conclude that the Commission's proper role in this matter is that of a responsible agency, and consistent with the extent of its jurisdiction, is limited to determining the adequacy of water supply to meet the needs of Valencia's present and future customers.

A. Position of Ventura

Ventura argues that CEQA does not permit the Commission to limit its statutory responsibilities to that of a responsible agency. Ventura relies on *Planning & Conservation League v. Department of Water Resources* (2000) 83 Cal.App.4th 892, 903-905. Ventura characterizes the WMP as "a continuing program with an interim 10-year Los Angeles County Development Monitoring System (DMS) horizon and long-term 20-year planning horizon." Ventura contends that as a "lead agency" having the principal responsibility for approving the WMP, which may have a significant effect on the environment, the Commission must require an EIR to be prepared for the WMP. According to Ventura, ALs 88 and 90 are sub-projects supported by EIRs prepared for their underlying land developments with an incremental water demand of about 5,011 AFY. Ventura contends that the WMP on which the ALs rely is the larger project planning document to inventory regional water supplies available in the amounts indicated to meet project demand for the 10- to 20-year horizon of the WMP. Ventura argues that CEQA review of such general planning documents should be accomplished by a program EIR to evaluate a series of actions related geographically as logical parts of a chain of contemplated actions. Ventura cites *Sierra Club v. County of Sonoma* (1992) 6 Cal.App.4th 1307, 1316.

B. Position of Sierra Club

Sierra Club argues that the Commission must assume the role of lead agency for CEQA purposes and address every potentially significant effect caused by usage of all the water resources shown as available in the WMP. According to Sierra Club, no agency has prepared an EIR on the impacts of Valencia's WMP, and none of the development project EIRs that Valencia submitted for Commission review addresses the cumulative impacts of Valley-wide water demands in the WMP's 10-year growth projection.

C. Position of Valencia

Valencia contends that Ventura has misunderstood the scope and contents of the EIRs[3] that were prepared, approved, and certified by the local lead agencies for the four land development projects for which ALs 88 and 90 propose that Valencia should provide water service. Further, Valencia disputes Protestants' arguments that (1) the four development project EIRs "did not even purport to evaluate any impacts beyond the incremental 5,011 AFY demand"; and (2) "if the Commission does not require an EIR for this WMP, no environmental review of the Santa Clarita Valley regional water supply delivery capability will ever occur." Valencia points out that the two most recent of these EIRs, in particular, include cumulative impact assessments, especially focusing on the adequacy of water supplies to meet long-term growth to the extent of full build-out of the Santa Clarita Valley, including the Newhall Ranch Specific Plan.

Valencia also points out that the EIRs evaluated not only the demand projected for the immediate projects and Los Angeles County's DMS buildout, which is within the scope of the WMP, but also CLWA's Integrated Water Resource Plan (IWRP) Valley-wide buildout scenario, extending well beyond the WMP both in time and scale. Valencia submits that the cumulative

---

[3] Or, for the Mountain View project, the Mitigated Negative Declaration.

environmental impacts analysis presented in those EIRs includes just the type of "environmental review of Santa Clarita Valley regional water supply delivery capability" that the Protestants are concerned will never be done if the Commission does not do it with respect to the WMP.

D. Discussion

We endorse the principle that a utility project must satisfy environmental review, including (where appropriate) the review of cumulative impacts of the project in conjunction with other projects. We find, however, that the projects at issue here have received environmental review from other permitting authorities, and we may satisfy our own CEQA duties within the role accorded a responsible agency.

In the case before us, it is the extension of Valencia's water service to the four development projects covered by ALs 88 and 90 that must be the subject of the Commission's environmental assessment. The extension of such water service was one element of each development project, and the environmental impacts of the extension of water service were assessed and studied within each of the environmental topical areas addressed by each of the four development project EIRs. Each of the EIRs included a chapter on "Water Resources" and a chapter on "Water Service," and these chapters of the most recent EIRs – for the North Valencia 2 and West Creek developments – analyzed data and reached conclusions similar to those presented in Valencia's WMP.

None of the EIRs prepared for the North Valencia 2, Mountain View, Tesoro del Valle, or West Creek developments concluded that there would be significant impacts with respect to water service or water supply. All of the EIRs concluded that there were no significant water supply impacts, as an adequate supply of water existed for the anticipated demand of all projects within the then-current DMS, which included the cumulative demand of all four of those projects. Accordingly, the analysis of water facilities construction and water resource issues in these EIRs is sufficient for the Commission's consideration of the environmental impacts of the present project - "review and approval of the WMP in conjunction with ALs 88 and 90."

Approval of the advice letters by the Commission will entitle Valencia to serve the four development projects associated with the advice letters. Approval of the WMP will not "entitle" Valencia to pump groundwater or to take deliveries of SWP water from CLWA. Those "entitlements" already exist. In fact, because the groundwater basin that Valencia serves is unadjudicated and because of CLWA's "first come, first serve" policy for distributing SWP water, Valencia and the other three water purveyors in the basin (Santa Clarita Water Company, Newhall County Water District, and Los Angeles Water District No. 36) require no additional entitlement to obtain the water supplies they may need to serve customers within their authorized service areas. The only entitlement before the Commission is for Valencia to expand its service area to serve the four new developments.

The relevant EIRs have already considered, and mitigated as necessary, the potential environmental impacts of the provision of water service to the four land development projects. In the relevant EIRs, the only additional consideration presented by Valencia's ALs 88 and 90 is whether Valencia should be the provider of that water service. We find that Valencia's ready access to sources of water supply and the contiguous location of the land developments to its present service area make it the lower cost provider of water service to the future customers in these developments.

Considering the shared character of the water resources available to Valencia and other retail water purveyors in the Santa Clarita Valley, such as the unadjudicated groundwater basin and the water resources, including SWP water, available on a "first come, first served" basis through CLWA, it can be seen with certainty that there is no possibility of significant environmental impacts arising from the choice of Valencia, rather than one of the other retail purveyors, to provide water service to the North Valencia 2, Mountain View, Tesoro Del Valle, and West Creek developments. Accordingly, we conclude that no further review of environmental impacts is required with regard to the Commission's authorization of Valencia to be the water provider.

The CEQA Guidelines define a "responsible agency" as "a public agency which proposes to carry out or approve a project, for which a lead agency is preparing or has prepared an EIR or negative declaration." (14 Cal. Code Regs. ("CEQA Guidelines"), § 15381.) For purposes of CEQA, the term "responsible agency" includes all agencies other than the lead agency that have "discretionary approval power" over the project. (*Id.*) The approvals referred to in the definition are those *within the jurisdiction* of the responsible agency, rather than approval of the project as a whole. (See, e.g., Public Resources Code § 21153(c).)

In the present case, the Commission has responsibility for approving ALs 88 and 90, which are necessary water service approvals for the four land development projects whose respective EIRs were certified either by Los Angeles County or the City of Santa Clarita as lead agencies. Thus, the Commission is a responsible agency with respect to providing water service to each of those approved projects.

To comply with CEQA, a responsible agency must consider the final EIR prepared by the lead agency and reach its own conclusions on whether and how to approve the project involved. (CEQA Guidelines 15096(a), (f).) Before reaching a decision, a responsible agency must consider the environmental effects identified in the EIR of those activities that it is required to approve or carry out (in this case, the provision of water service), and it must independently decide whether to require additional environmental documentation. (Pub. Res. Code § 21002.1(d); CEQA Guidelines 15096(a), (f).) Under CEQA Guideline 15096(g)(1), a responsible agency need consider and adopt alternatives or mitigation measures designed to mitigate or avoid direct or indirect environmental effects *only with respect to those parts of the project it decides to* carry out, finance or *approve*.

A responsible agency, like a lead agency, must make the findings required by Public Resources Code § 21081 and CEQA Guideline 15091. In view of the limited scope of the responsible agency's role, it is sufficient for a responsible agency to indicate it has considered the EIR and to make or adopt findings only for environmental impacts that will result from the responsible agency's decision and that are subject to its jurisdiction.

Thus, as a responsible agency with respect to the provision of water service for the four approved development projects that AL 88 and 90 propose to have Valencia serve, the Commission's obligation is to review the EIR for each of the development projects with particular attention to the discussion of, and findings on, the environmental impacts related to water resources.

The Commission, in its role as responsible agency, has reviewed the EIRs and the WMP. Furthermore, this proceeding has produced a thorough and extensive evidentiary record covering the supply and demand requirements of the water purveyors in the Santa Clarita Valley, including Valencia, for the time frame covered by the WMP. This proceeding has entailed one interim decision by the Commission, numerous rulings, two prehearing conferences, testimony by 18 expert witnesses, eight days of hearings covering 1,100 transcript pages, and receipt into evidence of 66 exhibits. This record amply supports our determination to act as a responsible agency under CEQA.

We now turn to Ventura's arguments regarding the proper application of CEQA in this proceeding. Ventura contends that CEQA requires the Commission, before approving Valencia's WMP, to evaluate the environmental impacts of increases in groundwater pumping over the next 20 years to the levels shown as available in the WMP. According to Ventura, "[t]he decision at issue now is the approval of Valencia's WMP," and so "the long-term consequences of the WMP's increasing reliance upon groundwater sources to meet cumulative regional demand" must be the subject of CEQA review.

In this proceeding, the Commission determined that the WMP "in conjunction with" ALs 88 and 90 was a "project" for CEQA purposes. The combination of a general WMP plus the advice letter specific requests for entitlements on the basis of that WMP is what the Commission found to comprise a "project" requiring assessment of potential environmental impacts. (D.00-10-049, mimeo. at 22, 24 (Conclusion of Law 1).

Ventura refuses to accept that the application of CEQA to this proceeding is with respect to "the WMP in conjunction with ALs 88 and 90." According to Ventura, "this proceeding concerns three separate requests for approval" of the WMP, AL 88, and AL 90, and "the language 'in conjunction with' does not permit CEQA review of ALs 88 and 90 instead of the WMP." Nor, according to Ventura, may the Commission substitute EIRs prepared for the four development projects for CEQA review of the WMP as a whole, or focus environmental impact assessment on the incremental demand increase of 5,011 AFY for ALs 88 and 90 instead of the regional impacts of supplying water in the quantities listed in WMP Figure III-2, attached as Appendix A to this decision.

We believe that Ventura's position is unsustainable either procedurally or substantively. Procedurally, the definition of the "project," for CEQA purposes, is "the WMP in conjunction with ALs 88 and 90." D.00-10-049 made that determination, and the Assigned Commissioner's ruling of December 21, 2000 confirmed it. But the WMP, standing alone, is not a "project," and so it makes no sense and it is not legally required for the Commission to undertake a review of the potential environmental impacts of the possible use of all the water resources that the WMP presents as "available" over the ten to 20-year forecast period of that document.

While recognizing the applicability of CEQA to the "project" that was "the WMP together with ALs 88 and 90," the Commission also noted that local lead agencies had prepared EIRs for the land development projects to which AL 88 and AL 90 relate, and saw no reason to duplicate CEQA reviews already conducted by those lead agencies. This is why the Commission ordered Valencia to submit, along with its PEA, copies of any EIRs relating to the advice letters and evidence of any final local agency actions relating to those EIRs. (D.00-10-049, mimeo. at 22-23, 25 (Ordering Paragraph 1).)

Ventura complains that Valencia's approach entirely avoids CEQA review of the WMP. That is not true. Valencia has accepted the need for environmental assessment with respect to the defined "project" – the WMP in conjunction with ALs 88 and 90 – and has furnished all relevant documentation used by the local lead agencies that conducted full-blown EIRs with respect to the development projects that ALs 88 and 90 proposed to serve. Analysis of the environmental documentation for those projects, including the demand projected for the DMS buildout and for the long-term WMP Valley-wide buildout scenario as provided with the PEA, reveals a high degree of consistency with the evidentiary record developed in this proceeding with respect to the WMP.

Ventura claims that CEQA requires evaluation of the environmental impacts of "making available" the quantities of water estimated in WMP Figure III-2, with particular attention to "making available" the increment of water supplies estimated in comparison to what is now being relied upon. The problem with this assertion is that the WMP does not, and Commission approval of the WMP will not, "make available" any water supplies. The WMP merely estimates the volumes of water resources that are and will become available from various sources. To that extent, the WMP is – as noted above – simply a planning document.

Ventura's reliance on *Planning & Conservation League v. Department of Water Resources* (DWR) (2000) 83 Cal.App. 4th 892, 903-905 is misplaced. The issue in that case was the delegation of DWR's responsibility to prepare an EIR to another party. In the case before us, there is no such delegation – the EIRs have been prepared and certified by the lead agencies for the four development projects that are the subject of ALs 88 and 90. Also, the Commission is not delegating the responsibility for preparing an EIR for the WMP itself, because no such EIR is required for the WMP standing alone.

The Commission was clear, in this case, to identify the "project" for CEQA purposes as the WMP "in conjunction with" ALs 88 and 90.

Some of the actions that will "make available" new sources of water supply for the Santa Clarita Valley will be actions already taken or to be taken in the future by public agencies such as CLWA or by private entities that require permits or planning approvals from local or state agencies. Those actions will call for assessment of potential environmental impacts in accordance with CEQA. The WMP does not have such impacts; its impacts arise in connection with the demand-related entitlements – ALs 88 and 90 – that may be granted in conjunction with approval of the WMP and that may generate a 5,011 AFY near-term increase in Valencia's water demand. It is the impacts associated with that 5,011 AFY demand increase that are properly the subject of CEQA review in connection with this proceeding. These and other impacts of the four development projects are fully addressed in the four sets of environmental documents already completed and certified by the local agencies.

Given the Commission's role as a responsible agency reviewing EIRs certified by local lead agencies, Ventura's citation to the *County of Sonoma* case and its "low threshold requirement for initial preparation of an EIR" is simply beside the point – EIRs have been prepared and certified by the lead agency which include extensive analyses of project and cumulative impacts on water supplies. As responsible agency, the Commission has reviewed those EIRs and the findings supporting them. The EIRs did not identify any significant environmental impacts related to water service or water supply. No further CEQA review is required.

We believe that the analyses in these EIRs are sufficient to meet the requirements of CEQA. The local lead agencies have approved and certified all the EIRs, and their actions are final and no longer subject to judicial review, except in the case of West Creek, for which a timely petition for writ of review was filed and remains pending, but without any injunctive effect.

V. The WMP[4]

WMP Figure III-2 summarizes total water supply available for Valencia and the other retail purveyors. It shows a range of supply from 156,900 acre-feet (AF) to 142,800 AF from wet years to dry years, respectively, with the relatively high "dry year" value achieved through inclusion of "firming" supplies.

Protestants contend SWP deliveries, especially during drought years, will not be sufficient to avoid overpumping, thereby causing permanent damage to the groundwater basin. Also, Protestants contend that the reliance on certain groundwater supplies should be reduced, due to a contamination problem, and that water demand for the proposed Newhall Ranch Specific Plan should be included in the WMP.

---

[4] The Urban Water Management Planning Act, Water Code § 10610 *et seq.*, originally enacted in 1983, requires every urban water supplier – of which Valencia is one – to prepare and adopt an urban water management plan (UWMP) and to update its plan at lease once every five years. (§§ 10620, 10621.) The adopted and amended plans must be filed with DWR, which must, in the succeeding year, submit a report to the Legislature summarizing the status of such plans. (§ 10644.) Water purveyors, such as Valencia, are required to include in their UWMPs descriptions of their service areas, identification of existing and planned sources of water, description of the reliability of their water supplies, quantification of past, present and projected water use, and description of water demand management measures being implemented or planned. (§ 10631.)

Similarly, the Commission, following its investigation into the effects of drought on the regulated utilities, requires Class A water utilities to file a WMP with each general rate case application (D.90-08-055). Typically, a WMP filed with the Commission is an updated version of the water utility's last UWMP, as is Valencia's WMP filed in this proceeding.

Valencia disputes these assertions. Among various rebuttal arguments, Valencia endorses CLWA's management practice of securing additional entitlements and "firming supplies" only three to five years before needed, to avoid imposing unneeded costs on its current customers.

We find that the WMP provides a reasonable estimate of the water supplies available, including groundwater from the Alluvial Aquifer and the Saugus Formation, imported water from SWP, supplies to be acquired through CLWA's capital improvement program, and recycled water. Also, we find that CLWA's plan for short-term drought, firming water supplies when availability of SWP water is reduced in times of drought, is reasonable, and that the WMP need not be modified to account for the Newhall Ranch Specific Plan. These findings are discussed and supported below.

A. Water Demand

WMP Figure III-2 shows that the updated demand for both existing and Valley-wide DMS build-out is calculated as 87,010 AF. The WMP relies on Los Angeles County's DMS to forecast future water demands, noting that the County maintains DMS and includes in that data base existing and projected water demands from all development projects for which a tract or subdivision map has been filed. According to Valencia, the County's DMS report provides the most accurate and up-to-date summary of all building activity and corresponding water demands likely to receive water service from Valencia and the other retail purveyors in the foreseeable future.

For Valencia itself, the WMP report estimates total demand of 23,088 AF in 2000 rising to 32,406 in 2010 and 40,978 AF in 2020. This forecast for Valencia reflects an annual usage factor for single-family residential connections of 0.6 AFY and a long-term growth rate of 800 customers per year. Similarly, in accordance with the Commission's preferred methodology, Valencia calculates demand separately for each customer class and aggregates the result.

Donald Howard, a civil engineer with experience performing technical studies and testifying before the Commission on behalf of a range of water utilities, prepared an independent analysis of future water use for Valencia. He concurred with Valencia's analysis of usage by customer class, and performed his own study using a Commission-recommended forecasting program. The results of his study indicated somewhat lower future usage by the bulk of Valencia's customers than projected in the WMP. To be conservative, he recommended using the Valencia's WMP results for long-term purposes, but believed his projections were more accurate for the shorter term. Howard's testimony is uncontroverted.

Protestants asked our consideration of the long-term consequences of planning changes under consideration by the County of Los Angeles in connection with the Newhall Ranch Specific Plan. This is a project of the Newhall Land and Farming Company that may eventually lead to the construction of real estate developments including some 21,000 homes. Robert DiPrimio, Valencia's president and policy witness, stated that the WMP's demand projections do not account for development that may occur pursuant to the Newhall Ranch Specific Plan, because no tract maps have yet been filed with the County for any significant portion of such developments, and so the water demands associated with such developments are not in DMS. He testified that as a water utility manager, he was unwilling to include in his Water Management Program such projects that do not have local approval and are not included in DMS. When asked about the sources of water supply if Valencia were to serve the Newhall Ranch Specific Plan, he refused to speculate, noting that the proponents of that as-yet unapproved project were proposing sources of supply that may be additional to those reflected in the WMP.

DiPrimio explained that the DMS does not have a time frame associated with it, but he estimated that it covers approximately ten years of development activity. He stated that the WMP's projections of demand for Valencia's own operations, however, look 20 years into the future. These longer-term demand projections do not take into account the prospects for serving Newhall Ranch Specific Plan or any other specific development – they are simply based on an extension of Valencia's long-term experience of residential customer growth at an average rate of 800 customers per year.

He argued that this long-term estimate reflects upswings and downswings in the economy, and so is useful regardless of any specific land development plan that might be approved. He viewed the 800 customers per year growth estimate as "conservative" (on the high side). He pointed out, based on his experience, that in the late 1980s there had been a significant level of growth in the Santa Clarita Valley and when the recession occurred, the number of new customers dwindled to practically zero.

We find that the WMP does not need to separately take into account at this time any additions that may result from the Newhall Ranch Specific Plan. To the extent that any part of the project gets built, in the near term, it is accounted for in the WMP by the 0.6 AFY usage figure and the customer growth rate of 800 customers per year testified to by witnesses Howard and DiPrimio. In any event, Newhall Ranch Specific Plan is not included in ALs 88 and 90. If Valencia proposes to serve Newhall Ranch Specific Plan, we will require the company to file an application requesting authority to expand its service area, provide an updated WMP and advice letter covering any such project. In the meantime, for purposes of approving the WMP in conjunction with ALs 88 and 90, we find the demand forecast set forth in the WMP to be reasonable.

B. The Alluvial Aquifer and the Saugus Formation

Water purveyors in the Santa Clarita Valley pump their groundwater supplies from two aquifers: the Alluvial Aquifer and the deeper Saugus Formation.

For the Alluvial Aquifer, WMP Figure III-2 shows as available 40,000 AFY in a wet year and 32,500 AFY in a dry year. For the Saugus Formation, it shows as available 20,000 AFY in a wet year and 11,000 AFY in a dry year. Sierra Club and Ventura say these groundwater resources would be overpumped, if pumped to the full extent shown.

Sierra Club foresees a shortfall in water supply if the Newhall Ranch Specific Plan is built within the 10-year planning horizon of the WMP and SWP supplies are curtailed to 4,562 AFY as happened in 1991. Sierra Club contends that even if as shown in WMP Figure III-2, the Alluvial Aquifer and Saugus Formation provide 43,500 AFY in a dry year, these aquifers would supply less than half of the 104,000 AFY demand requirement. According to Sierra Club, such accelerated pumping would overdraft the aquifers at a rate never experienced before.

Ventura has similar concerns. Ventura argues that pumping at rates considerably in excess of the combined average historical pumping rate of about 36,000 AFY would greatly stress the groundwater basin, more so with the addition of the Newhall Ranch Specific Plan.

Valencia disputes the assertions. Valencia witness Joseph Scalmanini, a consulting engineer with expertise in groundwater hydrology, found no long-term trends toward overuse of these aquifers. In reviewing groundwater level data, Scalmanini consistently found that groundwater levels over the last 30 years were generally higher than over the preceding two decades (the 1940s and 50s). He also found that groundwater quality variations in the Alluvial Aquifer correlated inversely with precipitation and stream flow, without any sustained trend toward water quality degradation. He endorsed the groundwater management practices of maximizing use of the Alluvial Aquifer in the context of a previously reported perennial yield of 32,500 AFY. He noted that this management practice includes intermittent "stressing" of the aquifer by pumping in excess of the perennial yield value for one or more years, without long-term adverse effects.

Regarding the Saugus Formation, Scalmanini testified that there has been no quantification of its perennial yield, although Richard Slade recently estimated short-term yield of up to 40,000 AFY. He also found support in recent experience for a management approach that contemplates pumping up to 40,000 AFY from the Saugus Formation in drought years, followed by periods of lower pumpage to allow recovery of water levels and storage. He considered the components of the overall groundwater supply shown in WMP Figures III-2 to be "very conservative," and he particularly endorsed the logic of relying on the Saugus Formation for firming water supply in dry years.

The only contrary witness with expertise in hydrology was Ventura's Steven Bachman. He presented an analysis of the adequacy of water supplies for Valencia's future use by comparing a long-term demand curve included in CLWA's draft IWRP with a significantly modified version of the available supplies shown in WMP Figure III-2. His major departures from the WMP were to set a maximum dry-year yield from the Alluvial Aquifer of 25,000 AFY and to look to the Saugus Formation as the only source for dry-year firming supply, discounting to zero the prospects for firming from other sources, both State and private. Based on these and other assumptions, Bachman concluded that the Saugus Formation would be in perpetual overdraft beginning in 2011. Bachman also considered water quality data that suggested to him a general deterioration of water quality in the Saugus Formation, as measured by total dissolved solids (TDS), with increased pumping.

Valencia argues that Bachman's assessment of the WMP's supply scenarios was arbitrary. According to Valencia, a fundamental defect in Bachman's approach was that he contrasted a current snapshot of supply availability to a trend line of demand growth 10, 20, and even 50 years into the future. Valencia witness DiPrimio considers the IWRP's Valley build-out scenario, the source of Bachman's 50-year view, beyond the scope of the WMP and this proceeding. According to DiPrimio, Bachman also disregarded numerous potential future water supplies available to CLWA and the retail water purveyors, and the fact that beyond a relatively modest baseload contribution, the Saugus Formation is intended to be used to meet demands when imported water supplies are reduced during droughts.

Valencia witness Richard Slade addressed Bachman's claim about deteriorating water quality in the Saugus Formation. He studied the same data and concluded that although TDS had increased slightly over time in all five wells studied, the TDS increase was not related to groundwater production from any of the wells. He found "no evidence to suggest that more intensive pumping of the Saugus Formation will increase TDS concentrations in the water supply."

Sierra Club witnesses Plambeck and Kotch challenged Valencia's planned reliance on groundwater resources. Plambeck asserted that the Santa

Clara River "has been over-drafted beyond its safe, perennial yield for the past six years and in 1999 it was over-drafted by more than 10,000 AF." She also claimed that there was no hydrological study that supports extraction from the Saugus Formation of more than 20,000 AFY. Likewise, Kotch pointed to a "trend of overextraction" from the Alluvial Aquifer.

Valencia witness Scalmanini contends that Plambeck's and Kotch's assertions about "overdrafting" from the Alluvial Aquifer fail to recognize that the perennial yield of an aquifer system is a long-term value, and that "overdraft" cannot be concluded simply because recent pumping has exceeded a long-term average number, even if for several years. Further, Scalmanini dismissed the assertion that the system has been pumped in excess of perennial yield over the past six years as not "even close to correct" – especially in view of the "absolute[ly] constant water-level condition throughout the time period that you're asking me about." In short, Valencia believes that its estimate of available groundwater resources and its reliance on those resources to meet both normal and dry year needs, is reasonable.

We find the WMP's reliance on groundwater from the Saugus Formation is within reasonable limits, and we reject Ventura's contention that the Saugus Formation will be in overdraft by the year 2011. Ventura witness Bachman reached this conclusion by using a demand figure of 105,500 AFY for the year 2010 obtained from CLWA's draft IWRP report. He compared this demand figure to the supplies shown as available in the WMP after making downward adjustments to firming supplies. The point that Bachman overlooks is that the supplies shown as available in the WMP are the supplies shown as available for a demand of 87,000 AFY rather than the 105,500 AFY IWRP demand figure he used. Obviously, such a mismatch would provide the shortage (overdraft) that Ventura forecasts. In short, Ventura has made an "apples and oranges" comparison. We need not address the other adjustments made by Bachman to WMP firming supplies, because Bachman's use of the 105,500 AFY IWRP demand figure overshadows everything else.

C. The Perchlorate Problem

Ammonium perchlorate contamination has been recently detected in four Saugus Formation wells located in or near the Porta Bella property. The parties disagree on how the WMP must account for that fact. Protestants argue that the extent of contamination has not been identified, increased groundwater pumping could spread the contamination, and clean-up might take several decades.

Valencia believes the problem has been fully identified and is well on the way to remediation. Valencia points out that a treatment facility has been licensed for operation in La Puente by the Department of Health Services (DHS), which has found that the technology employed by the facility can reduce perchlorate to a no-detect level.

Protestants cite data from monitoring wells that they believe shows the perchlorate is migrating toward production facilities now relied on for drinking water. Protestants conclude that to stop the migration, Valencia must reduce its pumping from this acquifer, and that the WMP should be revised to show correspondingly lower availability of water supply. Valencia, however, says these data show that groundwater is flowing westward but not that contamination is spreading; in fact, perchlorate has shown up only at the four wells where it was initially reported. Thus, Valencia believes its supply assumptions reasonably consider the perchlorate contamination problem and should not be adjusted.

We conclude that the record supports the WMP's analysis of the perchlorate problem. Specifically, planning for remediation is substantially under way, and production facilities sufficiently remote from the contamination site can be relied upon for the quantities of water that the WMP assumes will be available from the Saugus Formation. Furthermore, the close monitoring of the situation by the water purveyors, CLWA, the California Department of Toxic Substances Control (DTSC), and the U.S. Army Corps of Engineers, reasonably ensures a prompt response to any change in the situation. Consequently, for purposes of the WMP, Valencia is appropriately accounting for the impact of perchlorate contamination on its water supplies.

D. Supply From State Water Project and Firming Resouces

WMP Figure III-2 reflects 95,200 AFY of SWP water being available for use in a wet year, and 47,600 AFY available for use in a dry year. WMP Figure III-2 also shows 50,000 AFY of firming supplies available to make up the difference in SWP deliveries in a dry year.

CLWA is the SWP contractor or wholesaler of imported water for the Santa Clarita Valley. While CLWA's current SWP entitlement is 95,200 AFY, actual availability and delivery can be affected by a number of factors, including hydrologic and weather conditions and conflicting needs of the Sacramento-San Joaquin Delta.

Sierra Club argues that because the SWP must curtail deliveries in some years to as little as 20 to 30% of entitlements, the SWP cannot reliably make up the difference between the WMP's projected demand of 87,000 to 104,000 AFY (including Newhall Ranch Specific Plan), on the one hand, and the total sustained yield capacity of the Alluvial Aquifer and the Saugus Formation.

Regarding Valencia's proposals for securing firming supplies to make up this difference, Sierra Club argues that no documentation of contracts to secure such additional supplies has been provided.

Ventura's assessment, based on a probability analysis, is that the amount of SWP water likely to be received by CLWA is 34,272 AF or less in one year out of 20. Ventura notes that in 1991, the SWP delivered approximately 30% of the entitlement statewide and CLWA received 4,000 to 5,000 AF, or less than 10% of its then 54,200 AFY entitlement. Ventura discounts the availability of the firming supplies described in the WMP to make up any shortfall caused by reduced SWP supplies in a dry year.

Undoubtedly, SWP deliveries will be curtailed, perhaps substantially, in some years. Thus, the WMP's provisions for firming supplies are vital and should be considered together with SWP supply. We examine these provisions below.

The WMP defines "firming water supplies" as alternate short-term supplies (1 to 3 years) made available to local purveyors when imported water is reduced during drought conditions. The WMP refers specifically to three firming supply options: (1) acquiring additional SWP entitlement, (2) the Drought Water Bank, operated by the State of California through DWR, and (3) local supply augmentation. The WMP also refers to several other state programs CLWA can use to firm up SWP supplies when they are reduced, including the Supplemental Water Purchase Program, the Interruptible Water Purchase Program, and the SWP Turn-back Pool. A survey of additional future water resources also is provided.

CLWA witnesses Sagehorn and Takaichi explained that development of these resources is on an "as-needed" basis. CLWA seeks to anticipate and implement the capital improvements needed to satisfy future water demands without overly burdening its wholesale customers (and their current ratepayers) with the costs of these capital improvements. Because CLWA has taken past steps to increase its SWP entitlement well beyond current and near-term projected demand, and has sufficient capacity available on the California Aqueduct to ensure delivery of the supplies it needs, existing capital assets are sufficient to meet near-term demand. Nevertheless, CLWA is seeking additional SWP entitlements totaling approximately 19,000 AFY from two water districts in Kern County to meet incremental future demand and to enhance service reliability to existing users in the event of future statewide drought.

Sagehorn testified that CLWA has about 4,700 AF of storage in Pyramid and Castaic Lakes for surplus SWP water. He estimates that about 100,000 AFY could be produced for three years in an extended drought by storing unneeded SWP entitlements in underground basins. Sagehorn noted that since 1994, CLWA returned a total of 130,000 AF of water to the SWP, which could otherwise have been stored for use in drought years.

Also, Valencia witness Dendy testified that in a statewide dry year, up to 20,000 AF could be made available to CLWA through the State Water Bank. According to Dendy, the record supports that reliance and even greater amounts, if needed.

For planning purposes, the WMP assumes that Valencia's customers could voluntarily conserve 10% from their normal usage. Valencia believes this is a reasonable and, in fact, conservative assumption given that Valencia's customers voluntarily conserved over 20% during the severe drought year of 1991. However, the WMP does not expressly factor conservation or "demand management" into either the demand or the supply side of its balance of resources. Thus, this factor does not appear in WMP Figure III-2 either as an adjustment to the various demand levels or as an element of firming supply. Where conservation does come into play is in the definition of Valencia's water reliability goal. That goal, as part of its effort to balance the provision of reliable service with economical operations, is to meet water demands (unadjusted for conservation) 95% of the time, or in 19 out of 20 years. In the remaining 5% of the time, the maximum contemplated supply shortage is 10% – the presumed level of conservation. As DiPrimio testified, planning instead to serve normal demand in a critically dry year would require Valencia and CLWA to invest prematurely in alternative water supplies that might never be needed, producing a significant cost burden to local water companies and their customers.

The Santa Clarita Valley's water purveyors have reserved the Saugus Formation as a firming resource and have decided to maximize production from the shallower Alluvial Aquifer, from which water can be pumped at lower cost. Valencia estimates that, if needed, the Saugus Formation could provide 40,000 AF of firming supplies.

WMP Figure III-2 shows 1,700 AFY of recycled water as available in both wet and dry years. DiPrimio estimated the potential production of recycled water to be at least 10,000 AFY, with the costs declining as a function of increasing production. Such increased production of recycled water for golf courses and landscaping uses makes more supplies of potable water available for residential use.

In summary, Valencia believes that the availability of the range of firming resources described above, now and in the future, substantially obviates any grounds for serious concern about the uncertainty of obtaining full deliveries of SWP entitlement in any particular year.

We find that Valencia has reasonably demonstrated the availability of firming supplies of the magnitude indicated in the WMP. These supplies, in turn, support our finding that the WMP's reliance on SWP water is reasonable.

E. Conclusion

Contrary to the assumptions of witnesses for Sierra Club and Ventura, the amounts of water supply from the various sources listed in WMP Figure III-2 are not presented as an operational plan for how supplies would be used in a particular wet or dry year. The amounts simply show the range of water supplies available to the Valley under a range of weather conditions. The optimal mix of supplies used in a particular year is necessarily a function of prudent management choices by Valencia and the other purveyors based on the conditions in that year. These choices are available because Valencia and the other water purveyors have, as Scalmanini testified, about twice as much supply as there is projected demand.

DiPrimio made a similar point, applicable to the range of water resources available to Valencia, when he testified that:

> "The WMP estimates the availability of groundwater from the Alluvial and Saugus aquifers in a wet year and a dry year scenario, but extraction of water at the levels of these estimates would not be required, in most years, to meet the level of demand presented by the addition of the AL 88 and 90 extensions to Valencia's service area. In any single year and in any series of years, Valencia and other water purveyors in the Santa Clarita Valley will look to a variety of sources to meet the current year's demand. These include water transfers and exchanges, groundwater banking programs, participation in DWR's dry-year supplemental program, voluntary conservation and additional withdrawals from the groundwater basin. . . . The WMP

> estimates supplies that are and will be available – it does not mandate their use." (Exhibit 53 (DiPrimio), at 3.)

In short, the WMP does no more than create a baseline of expectations, at a particular point in time, of the water purveyor's supply and demand. The WMP does not dictate management choices among presently available sources of supply or timely investment in new resources. When performed intelligently, these management choices can augment the available resources while both limiting the incurrence of costs that must be passed on to customers and also avoiding the potential environmental harms that rightly concern the Protestants, and indeed this Commission.

The evidence developed in this proceeding strongly supports the finding that for the relevant forecast period, Valencia has water resources available to meet projected customer demand for its services, including the demand presented by <u>all</u> new development accounted for by Los Angeles County's DMS. The WMP and the related evidentiary record developed in this proceeding is clearly adequate for the Commission to act on Valencia's proposal to extend water service to the four developments covered by ALs 88 and 90. Extending service to large-scale future developments, such as those that may result from the Newhall Ranch Specific Plan, will call for review of more current information, such as the 2000 UWMP or a future update to this WMP. If Valencia proposes to serve this development, it must file an application, an updated WMP and advice letter for such a project.

As is evident from WMP Figure III-2, the increment of demand represented by ALs 88 and 90 comes nowhere near taxing the water resources available to Valencia in a wet or dry year. As discussed in the first half of today's decision, the environmental impacts associated with approval of the WMP in conjunction with those advice letters, including cumulative impacts, were fully addressed by the EIRs completed and certified in connection with the underlying land development projects. Accordingly, we approve Valencia's WMP.

Valencia has facilities in place that can be extended efficiently into the development areas proposed to be served by ALs 88 and 90. The demand the proposed service extensions would add to Valencia's overall service requirements is modest and well within Valencia's demonstrated water production capacity in both normal and dry years. The extension of Valencia's service area will incorporate development areas that already are enclosed on three sides by Valencia's territory. If Valencia is not authorized to extend its service, one of the other retail water purveyors, drawing from the same shared water resources, will likely take Valencia's place. If that development ultimately is served by another water purveyor rather than Valencia, the cost to extend service will be substantially higher, and the reliability of service less, than what it would be for Valencia. Therefore, the public interest – and particularly the interests of water users in the Santa Clarita Valley – will be served by today's decision approving ALs 88 and 90.

VI. Comments on Proposed Decision

The proposed decision of the ALJ in this matter was mailed to the parties in accordance with Pub. Util. Code § 311(d) and Rule 77.1 of the Rules of Practice and Procedure. Comments were filed on November 19, 2001, by Ventura, Sierra Club, and Valencia. Also, comments were received from DTSC and People for Environmentally Responsible Clean Up (PERC), both not parties to this proceeding. Reply comments were filed on November 23, 2001, by Valencia. We have reviewed the comments and made changes to the ALJ's proposed decision where appropriate.

Findings of Fact

1. By Resolution W-4154, the Commission ordered Valencia to prepare an updated WMP to enable the Commission and all interested parties to evaluate the effects of further expansion of Valencia's service area on its water supply.

2. On December 17, 1999, Valencia responded to Resolution W-4154 by filing its application seeking approval of its updated WMP.

3. Protests to the application were filed by Sierra Club, Ventura, and the Commission's Water Division.

4. On March 20, 2000, Valencia filed AL 88 seeking authority to expand its service area to include portions of two land developments known as North Valencia Annexation 2 and Mountain View.

5. On September 19, 2000, Valencia filed AL 90, requesting permission to extend service to two additional developments, West Creek and Tesoro del Valle.

6. On October 19, 2000, D.00-10-049, the Commission ruled that CEQA is applicable to the WMP together with ALs 88 and 90 and ordered Valencia to file

a PEA addressing the service area expansions proposed in the advice letters and reflected in the WMP, and also to submit copies of EIRs relating to the advice letters and evidence of final local agency actions relating to those EIRs.

7. On November 13, 2000, Valencia filed the required PEA and submitted EIR materials for each of the four underlying land development projects, and separately filed a motion for review and approval of ALs 88 and 90 in this proceeding, concurrently with its action on the WMP.

8. An assigned Commissioner's ruling issued December 21, 2000, confirmed the Commission's intent to consider ALs 88 and 90 in conjunction with the WMP and to conclude this proceeding with a single Commission decision addressing both substantive issues and CEQA review.

9. An ALJ's ruling issued May 11, 2001 noted that Commission staff had found the PEA to be complete for CEQA purposes for each of the four development projects Valencia seeks to serve by the pending advice letters, and set further hearings on the advice letters and to allow updating of the record related to the WMP.

10. Further prepared direct and rebuttal testimony was served in advance of two additional days of evidentiary hearings held in mid-June, 2001.

11. The proceeding was submitted for decision upon the filing of opening and reply briefs on August 27, 2001.

12. The WMP evaluates water supply and demand for the entire Santa Clarita Valley as well as for Valencia.

13. The WMP describes the primary sources of water supply available to Valencia as being groundwater from the Alluvial and Saugus aquifers, imported water from the SWP and potentially other supplies acquired through CLWA, and recycled water.

14. The WMP describes the role of firming water supplies in providing alternative short-term supplies when the availability of SWP water is reduced.

15. For estimating future demand, the WMP relies primarily on the projections of Valley-wide and company-specific water demand provided by Los Angeles County's DMS and on projections of growth in its own customer demand based on historical growth trends.

16. For the practical planning and management purposes of a retail water utility, use of the DMS for estimating future demand is more appropriate than use of a scenario that assumes total build-out of the Santa Clarita Valley to the fullest extent permitted by the relevant General Plans.

17. The DMS projections and Valencia's own historic trend of growth in demand provide consistent results indicating total demand for Valencia's services of approximately 32,000 AFY by the year 2010.

18. Water purveyors including Valencia customarily rely on DMS data as providing a reliable basis for estimating demand growth within the time frame appropriate for water system management and planning purposes.

19. Valencia's forecast of demand based on a 0.60 AFY annual usage factor for single-family residential customers is conservative and consistent with Commission-approved estimating methods.

20. Valencia's water reliability goal is to have sufficient supplies available to meet normal water demand in 19 out of 20 years while anticipating a maximum allowable supply shortage in one year of 10% of demand.

21. Diversity of water supply is beneficial in times of drought.

22. Perennial yield of an aquifer is that amount of groundwater that can be pumped from the aquifer over a long period of time without causing an undesirable result.

23. The record indicates that pumping from the Alluvial Aquifer has been and continues to be within the aquifer's perennial yield and that the aquifer is not and has not been in overdraft.

24. The management practice of Valencia and other local water purveyors is to maximize use of the Alluvial Aquifer in combination with imported SWP supplies in normal years while keeping the Saugus aquifer full and available for use during dry years.

25. The WMP's estimates of water supply available from the Alluvial Aquifer, in a range of 32,500 to 40,000 AFY, are consistent with current management practices and well within the aquifer's perennial yield.

26. The WMP's estimate of base water supply available from the Saugus Formation, in a range of 11,000 to 20,000 AFY, are consistent with current management practices and supported by recent experience.

27. The WMP's estimate that up to 30,000 AFY above the lower estimate of base water supply is available from the Saugus Formation as short-term firming supply in up to three consecutive dry years is supported by expert analysis.

28. Improper disposal of ammonium perchlorate at the Porta Bella property resulted in detection of perchlorate contamination in four production wells in the Saugus Formation.

29. Valencia, the other local water purveyors, CLWA, the property owner, the California Department of Toxic Substances Control, and the U.S. Army Corps of Engineers are all actively involved in efforts to characterize the extent of perchlorate contamination on and off the Porta Bella property and to implement remediation efforts.

30. Effective and practical methods are available and in current use for high-volume treatment of water supplies contaminated by perchlorate, allowing for

the restoration of such water supplies for public use and convenient disposal of waste products.

31. Large areas within the Santa Clarita Valley are viable for additional Saugus Formation production wells and sufficiently distant from the perchlorate-affected wells to allow pumping without practical effect on the incidence of perchlorate.

32. It is reasonable to anticipate that the water purveyors of the Santa Clarita Valley will effectively remediate the perchlorate problem originating at the Porta Bella property in a timely manner so as to preserve their ability to rely on the Saugus Formation as a dry-year firming resource.

33. Hydrology expert Scalmanini testified that the groundwater components of the WMP's supply estimates were "very conservative" and his testimony was not effectively refuted.

34. CLWA is a State water contractor with Table A Entitlement to SWP supplies totaling 95,200 AFY.

35. Receipt of full SWP entitlement in a particular year is not assured, but deliveries have been at least 50 % of amounts requested in almost all years.

36. The WMP's estimate that a range of from 50 to 100% of SWP entitlement will be available except in an extreme dry year is reasonable.

37. CLWA's adaptive management approach facilitates development of firming resources when needed at moderate cost.

38. The State has developed or is in the process of developing various dry-year firming supply programs, including the Drought Water Bank, to enhance the reliability of SWP water supplies to contractors such as CLWA.

39. CLWA and Valencia also have opportunities to develop water banking and storage projects and dry year option contracts directly with other owners of water resources.

40. CLWA is in the process of developing recycled water that will eventually produce more than 10,000 AFY of supplemental supply, but the WMP includes only 1,700 AFY of recycled water in its estimates of available supplies.

41. The WMP describes numerous water conservation programs conducted by CLWA and Valencia but does not recognize potential conservation in demand or supply projections.

42. The WMP Figure III-2 provides an accurate and useful comparison of the cumulative volumes of water supply available to water purveyors in the Santa Clarita Valley across a range of weather conditions in relation to current and projected Valley-wide demand over the relevant time period.

43. The comparison of available supply and projected demand presented in WMP Figure III-2 indicates the sufficiency of supplies available to Valencia over the relevant time period.

44. Valencia's current and planned water supplies are sufficient to meet present and future customer needs within the planning horizon of Los Angeles County's DMS.

45. The WMP adequately and fairly describes and estimates the current and future demand for Valencia's water service and the range of water resources reasonably available to Valencia now and in the future to meet that demand over the relevant time period.

46. DMS includes the water demand associated with the development projects addressed by ALs 88 and 90.

47. Valencia is the water purveyor that can most efficiently extend service to the development projects addressed by ALs 88 and 90.

48. The only entitlements Valencia seeks from this proceeding are the entitlements to extend water service proposed in ALs 88 and 90.

49. Two of the four development projects, North Valencia 2 and Tesoro del Valle, were the subjects of EIRs that have been certified and approved by the City of Santa Clarita and the County of Los Angeles, respectively, and are not the subject of any judicial appeal.

50. One of the development projects, Mountain View, was the subject of a Mitigated Negative Declaration certified and approved by the County of Los Angeles (following prior completion of an EIR for a larger project) and not the subject of any judicial appeal.

51. The fourth and most recent development project, West Creek, was the subject of an EIR that was certified and approved by the County of Los Angeles in September, 2000, but documentation of the County's actions was not adopted until December, 2000.

52. The County's certification and approval of the West Creek EIR has been challenged by SCOPE in an action, now pending in Santa Barbara County Superior Court, but no injunctive relief is in effect, a motion for preliminary injunction having been denied July 5, 2001.

53. In certifying and approving each of the above-referenced environmental assessments, the local agency adopted detailed findings and imposed specific mitigation measures as part of a comprehensive mitigation plan.

54. Valencia submitted with its PEA, or thereafter, complete documentation for the environmental review of the four land development projects related to ALs 88 and 90.

55. All environmental impacts that may be associated with the extensions of water service proposed by ALs 88 and 90 were within the scope of the environmental impact reviews that were performed in connection with the related land development projects.

56. The EIRs submitted in this proceeding did not identify any significant environmental impacts related to water service or water supply.

57. Pursuant to CEQA Guideline 15096(i), the Commission has considered the environmental assessments contained in the environmental documents for the related land development projects.

Conclusions of Law

1. The assigned Commissioner's ruling of December 21, 2000, correctly determined that the project under consideration in this proceeding, for purposes of CEQA, is the WMP in conjunction with ALs 88 and 90.

2. The WMP's projections of Valley-wide demand for water service based on DMS and of Valencia-specific demand based on the company's historic demand growth trend are reasonable and sufficient for Valencia's customer service and system planning purposes.

3. The WMP provides a sound basis for concluding that Valencia's current and planned water supplies are sufficient to meet present and future customer needs.

4. Valencia's water reliability goal of having available supplies sufficient to meet normal water demand in 19 out of 20 years while anticipating a maximum allowable supply shortage in one year of 10% of demand is reasonable.

5. The range of supplies the WMP projects as available from the Alluvial Aquifer and Saugus Formation is reasonable.

6. The range of SWP supplies the WMP projects as available is reasonable.

7. The sources and magnitude of dry-year firming supplies the WMP projects as available is reasonable.

8. The WMP's estimate of recycled water supply is reasonable.

9. The WMP's treatment of water conservation programs and potential is sufficient.

10. Environmental review is required with respect to Valencia's requests for entitlement to extend water service to the four development projects.

11. The proper role under CEQA for the Commission in considering approval of the WMP in conjunction with ALs 88 and 90 is that of a responsible agency.

12. As a responsible agency, the Commission's responsibility is to review and to consider the EIR or Mitigated Negative Declaration, as applicable, for each of the four land development projects to which ALs 88 and 90 relate in accordance with CEQA Guideline 15096(i) with particular attention to impacts on water resources, to determine whether further study is required, and to make appropriate findings.

13. Based on the evidentiary record developed in this proceeding and the environmental impact assessments prepared for the land development projects related to ALs 88 and 90, no additional review of environmental impacts relating to water resources is required.

14. Valencia's WMP should be approved.

15. Valencia's Advice Letters 88 and 90 should be approved.

O R D E R

IT IS ORDERED that:

1. Valencia Water Company's (Valencia) 1999 updated Water Management Program is approved to the extent that it establishes that Valencia has sufficient

water resources available to serve the projects described in Advice Letters 88 and 90.

2. Valencia is authorized to extend its service area to provide public utility water service to the North Valencia 2, Mountain View, West Creek and Tesoro del Valle developments as described in Advice Letters 88 and 90.

3. Advice Letters 88 and 90 are accepted for filing and shall become effective as of the date of this decision.

4. If Valencia proposes to expand its service area to serve the Newhall Ranch Specific Plan, or any part of it, Valencia shall file an application requesting authority to expand its service area, and provide an updated Water Management Program and advice letter covering any such service area expansion.

5. This proceeding is closed.

This order is effective today.

Dated November 29, 2001, at San Francisco, California.

Decision 03-10-063 October 16, 2003

BEFORE THE PUBLIC UTILITIES COMMISSION OF THE STATE OF CALIFORNIA

Application of Valencia Water Company (U-342-W) Seeking Approval of its Updated Water Management Program as Ordered in Commission Resolution W-4254 dated August 15, 1999.	Application 99-12-025 (Filed December 17, 1999)

ORDER STAYING DECISION 01-11-048, IN PART AND DENYING REHEARING OF DECISION 03-06-033

I. SUMMARY

On July 7, 2003 Sierra Club applied for rehearing of Decision (D.) 03-06-033, arguing that rehearing should be granted because the Second District Court of Appeal recently invalidated the West Creek Environmental Impact Report (EIR), which was one of the EIRs that we relied on in a decision precedent to D.03-06-033, D.01-11-048.[1] We have carefully considered each argument presented by Sierra Club and conclude that no ground for rehearing has been shown. While Sierra Club has failed to identify any legal error in our decision, we find, on our own motion, that we should stay D.01-11-048 insofar as it approves the West Creek EIR. This stay will be effective pending recertifiction of the West Creek EIR by the lead agency, Los Angeles County and resubmission of the West Creek EIR to the Commission.

[1] Sierra Club also applied for rehearing of D.01-11-048. The Commission hereby dismisses Sierra Club's application for rehearing of D.01-11-048 because it is out of time, pursuant to Public Utilities Code section 1731(b).

II. BACKGROUND

In D.03-06-033, we denied Sierra Club's Petition for Modification of D.01-11-048. In its Petition for Modification, Sierra Club argued that many of the facts upon which D.01-11-048 was based have changed or not come to pass, thereby affecting Valencia Water Company's (Valencia) ability to serve new customers. (D.03-06-033, p. 1.) In particular, Sierra Club requested that if we received notice that the West Creek EIR has been set aside, "that portion of Valencia's service area should be deleted" until recertification of the West Creek EIR. (Sierra Club's Petition for Modification, filed December 2, 2002, p. 4.) In denying Sierra Club's Petition for Modification, we stated that "it would serve no useful purpose to revisit Valencia's 1999 Water Management Project (WMP), since the Decision was based on the evidentiary record existing at the time [and that] [a] preferable approach is to look to Valencia's next WMP . . ." (D.03-06-033 at p.2.) We also found in D.03-06-033, that "Sierra Club's assertions regarding the West Creek EIR do not justify reopening this proceeding or modifying D.01-11-048." (D.03-06-033, p. 14, Finding of Fact 11.) At that point, the fact that the Court of Appeal invalidated the West Creek EIR was not in our record.

In D.01-11-048,[2] we approved Valencia's 1999 WMP and Advice Letters (ALs) 88 and 90, requesting permission to expand its service area. D.01-11-048 rejected County of Ventura's (Ventura) and Sierra Club's contention that we should assume the role of lead agency and issue an EIR on the WMP and all water supplies shown as available in the WMP before we address ALs 88 and 90.

---

[2] Ventura and Sierra Club applied for rehearing of D.01-11-048, challenging D.01-11-048 primarily on the grounds that the Commission erred in not acting as lead agency on the WMP, and therefore, the Commission failed to follow the requirements of the CEQA. The Commission denied Ventura's and Sierra Club's applications for rehearing of D.01-11-048 in D.02-04-002. Ventura and Sierra Club also filed petitions for writ of review of D.01-11-048 before the California Supreme Court, making identical arguments to their applications for rehearing. On June 19, 2002, the Court denied Ventura's and Sierra Club's petitions for writ of review.

In Application (A.) 99-12-025, Valencia sought approval of its updated WMP as ordered in Commission Resolution W-4154 dated August 5, 1999. Our approval of ALs 88 and 90 authorized Valencia to provide water service to the North Valencia 2, Mountain View, West Creek and Tesoro del Valle development projects. Under the particular circumstances of the proceeding, we decided that the California Environmental Quality Act[3] (CEQA) should apply. We determined that the WMP combined with ALs 88 and 90 constituted a "Project" under the CEQA. The EIRs[4] for these four development projects were previously certified by either Los Angeles County or the City of Santa Clarita acting as lead agency pursuant to CEQA. Therefore, we found it was unnecessary to duplicate the EIRs that had already been conducted by local lead agencies, and determined that our proper role on the Project was as a responsible agency. After considering the WMP in conjunction with ALs 88 and 90, we concluded that the WMP's demonstration of available water supplies gave a sufficient margin of safety to allow Valencia to serve new customers as delineated in ALs 88 and 90.

Sierra Club argues in its Application for Rehearing of D.03-06-033 that rehearing should be granted because the Second District Court of Appeal of California recently invalidated the West Creek EIR, which was one of the EIRs we relied on in approving the Project in D.01-11-048.[5] Sierra Club further contends that the court's invalidation of the West Creek EIR also negates the validity of the North Valencia-2 EIR because the North Valencia-2 EIR purportedly relies on the same water availability table as that in the West Creek EIR. (App. for Rehearing, p. 3.) As a result of the court's action, Sierra Club requests that we assume the role of lead agency under CEQA to review the WMP and ALs 88 and 90.

---

[3] CEQA is found at California Public Resources Code, Division 13, § 21000, et seq.

[4] Actually there were three EIRs and one mitigated declaration, but all four are hereafter collectively referred to as "EIRs."

[5] In D.03-06-033, we found that Sierra Club did not present sufficient evidence of problems regarding the West Creek EIR to justify reopening the proceeding.

III. DISCUSSION.

A. The Appellate Court Decision.

On February 27, 2003, the California Court of Appeal issued *Santa Clarita Organization for Planning the Environment v. County of Los Angeles*, 106 Cal. App. 4th 715, directing the trial court to issue a writ of mandate vacating the certification of the West Creek EIR and to retain jurisdiction until the Los Angeles County, the lead agency, certifies an EIR that complies with CEQA.[6] The Court of Appeal found that the West Creek EIR was inadequate because: (1) it did not calculate or discuss the differences between entitlement and actual supply with respect to the State Water Project (SWP); (2) there were no estimates from SWP as to how much water it could have delivered in wet years and in periods of drought; and 3) it was not sufficient for the EIR to simply contain information submitted by the public and experts, but rather, a detailed analysis of the information was required. (*Santa Clarita Organization for Planning the Environment*, 106 Ca. App. 4th, p. 716, 721-724.) Thus, the appellate court made it clear that the West Creek EIR was insufficient for CEQA purposes.

AL 88, filed on March 20, 2000 sought to expand Valencia's service area to the North Valencia Annexation-2, which includes Tracts 44831, 52667 and 52111, and Mountain View Tracts 46564, 46564-04, 46564-05 and 52302. On September 19, 2000, Valencia filed AL 90, which included West Creek Tract # 52455 and Tesoro del Valle Tract #56144. It is the portion of AL 90 relating to West Creek Tract # 52455 that was the subject of the Court of Appeal's decision. Acting as a responsible agency, we relied, in part, on the West Creek EIR attached

[6] In accordance with the Court of Appeals' Ruling, Judge James Brown of Santa Barbara Superior Court issued a Judgment Granting Peremptory Writ of Mandate. The Peremptory Writ of Mandate ordered the County of Los Angeles, lead agency on the West Creek EIR, to vacate and set aside the certification of that EIR, and ordered the lead agency to revise the water supply analysis in the EIR. Judge Brown also suspended all West Creek project activity that could have an adverse affect on the physical environment. (Judgment Granting Peremptory Writ of Mandate filed June 30, 2003 in the matter *Santa Clarita Organization for Planning the Environment v. County of Los Angeles*, Santa Barbara County Superior Court, Case No. 1043805, at 2:28-4:10.)

to AL 90 in deciding to approve the Project under CEQA in D.01-11-048. (D.01-11-048, pp. 13-20; 44, Ordering ¶ 2.) In D.03-06-033, we determined that Sierra Club did not present us with adequate evidence to justify changing our reliance on the West Creek EIR.

In its application for rehearing, Sierra Club has now brought the Court of Appeal decision to our attention. Because we relied on an EIR that the Court of Appeal has determined is insufficient for CEQA purposes, we will, on our own motion, stay that portion D.01-11-048 that approves the West Creek EIR until an updated West Creek EIR is certified by the lead agency, Los Angeles County. After certification by the lead agency, Valencia should file the updated West Creek EIR for our approval.

B. Sierra Club's Assertion that the Commission Should Assume the Role of Lead Agency for CEQA Purposes.

Sierra Club also contends that we should assume the role of lead agency and prepare a subsequent EIR on Valencia's WMP to "address and correct the deficiencies in the West Creek EIR and North Valencia-2 EIR . . ." (App. for Rehearing, p. 4.) Sierra Club's argument that the Court of Appeal's invalidation of the West Creek EIR necessarily invalidates the Valencia-2 EIR is untenable because Sierra Club did not challenge the North Valencia-2 EIR in court. Sierra Club's argument concerning the West Creek EIR is flawed because there is already a lead agency on the West Creek EIR, as the Court of Appeal recognized in its decision. (*Santa Clarita Organization for Planning the Environment,* 106 Ca. App. 4^{th}, p. 716.)

Moreover, we have repeatedly rejected Sierra Club's request to be lead agency for purposes of CEQA review in this matter.[7] We determined that the

[7] The Commission rejected becoming the lead agency in the following decisions: D.01-11-048, Decision Approving WMP and Authorizing Service Area Expansion; D.02-04-002, Decision Denying Rehearing of D.01-11-048; D.03-06-033, Opinion Deny Petition for Modification of D.01-11-048; and Answer of Respondent Commission to Petitions for Writ of Review, Certiorari,

Project in this proceeding for CEQA purposes is the WMP in conjunction with ALs 88 and 90. (D.01-11-048 at 17.) Because the four projects at issue in ALs 88 and 90 received environmental review from other local agencies, we concluded that we would best fulfill our duties under CEQA as a responsible agency.[8] (D.01-11-0148 at 13.) We reviewed the four EIRs and approved ALs 88 and 90 in compliance with our duties as a responsible agency.

Contrary to Sierra Club's position, the fact that the Court of Appeal invalidated the West Creek EIR because it determined that the analysis of water supplies was lacking does not signify that we committed legal error in acting as a responsible agency, rather than a lead agency, on the Project. The County of Los Angeles remains the lead agency on the West Creek EIR, and is responsible for correcting any deficiencies in the West Creek EIR per the Court of Appeal's decision. Therefore, our proper role on the Project, which includes the West Creek Development, remains that of a responsible agency.

IV. CONCLUSION

For the foregoing reasons, the Sierra Club's application for rehearing is denied and the D.01-11-048 is stayed insofar as it approves the West Creek EIR. This stay will remain in effect pending recertification of the West Creek EIR by the lead agency, and resubmission of the West Creek EIR to the Commission.

Mandamus, or Other Appropriate Relief filed by County of Ventura and Sierra Club (Case Nos. S105292, S105571; the California Supreme Court denied the Petitions for Writ of Review on June 19, 2002.)

[8] A responsible agency as defined under the CEQA Guidelines, is a "public agency which proposes to carry out or approve a project, for which a lead agency is preparing or has prepared an EIR or negative declaration." (D.01-11-048 at 15 (citing 14 Cal. Regs. 15381).)

Therefore **IT IS ORDERED** that:

1. Rehearing of D.03-06-033 is hereby denied.

2. D.01-11-048 is stayed insofar as it approves the West Creek EIR. This stay is effective pending recertification of the West Creek EIR by the lead agency, and resubmission of the West Creek EIR to the Commission.

2. This proceeding shall remain open.

This order is effective today.

Dated October 16, 2003, at San Francisco, California.

Decision 06-08-012 August 24, 2006

BEFORE THE PUBLIC UTILITIES COMMISSION OF THE STATE OF CALIFORNIA

Application of Valencia Water Company (U-342-W) Seeking Approval of its Updated Water Management Program as Ordered in Commission Resolution W-4254 dated August 5, 1999.	Application 99-12-025 (Filed December 17, 1999)

OPINION GRANTING MOTION OF VALENCIA WATER COMPANY TO REOPEN PROCEEDING AND TERMINATE STAY OF DECISION 01-11-048

Summary

Today's decision finds that with the recertification of the West Creek Environmental Impact Report (EIR) by the County of Los Angeles (County) the conditions stated in Decision (D.) 03-10-063 have been met; therefore, the stay of D.01-11-048 ordered by the Commission is lifted and Valencia Water Company (Valencia) is authorized to expand its service area to serve the West Creek project. This proceeding is closed.

Procedural Summary

On July 28, 2005, Valencia filed its motion to reopen this proceeding and terminate the stay of D.01-11-048, imposed by D.03-10-063. On August 12, 2005, Sierra Club filed its response in opposition to Valencia's motion. On August 22, 2005, Valencia filed a reply to Sierra Club's response. This matter is submitted for decision based on these pleadings.

Background

On November 29, 2001, in D.01-11-048, the Commission approved Valencia's Water Management Program (WMP), accepted Advice Letters 88 and 90 for filing, and authorized Valencia to extend service to four developments that were addressed by those advice letters. Further Commission decisions denied applications for rehearing and then a petition for modification filed by the Angeles Chapter of Sierra Club[1] (Sierra Club).

On October 16, 2003, in a decision addressing Sierra Club's application for rehearing of the decision denying its petition for modification of D.01-11-048, the Commission noted that a Court of Appeal decision recently had determined that the EIR for the West Creek project (West Creek EIR), one of the EIRs that the Commission had relied on in D.01-11-048, was insufficient for California Environmental Quality Act (CEQA) purposes. While finding no legal error in its decisions and denying Sierra Club's application for rehearing, the Commission acted on its own motion to stay D.01-11-048 insofar as it approved the West Creek EIR. The Commission directed that the stay of D.01-11-048 would remain in effect pending recertification of the West Creek EIR by the lead agency, the County, and resubmission of the West Creek EIR to the Commission. (D.03-10-063, *mimeo*., p. 7, Conclusion of Law 2.)

Recertification of the West Creek EIR

On September 26, 2000, the Los Angeles County Board of Supervisors certified the Final EIR for the West Creek project. Subsequently, various parties

[1] It includes Santa Clarita Organization for Planning the Environment (SCOPE).

challenged the County's certification of the Final EIR and project approval in an action in Santa Barbara County Superior Court (trial court).

On February 27, 2003, the California Court of Appeal directed the trial court to issue a writ of mandate vacating the certification of the West Creek EIR and to retain jurisdiction until the County of Los Angeles, the lead agency, certifies an EIR that complies with CEQA. The Court of Appeal found that the West Creek EIR was inadequate because: (1) it did not calculate or discuss the differences between entitlement and actual supply with respect to the State Water Project (SWP); (2) there were no estimates from SWP as to how much water it could have delivered in wet years and in periods of drought; and (3) it was not sufficient for the EIR to simply contain information submitted by the public and experts, but rather, a detailed analysis of the information was required. (*Santa Clarita Organization for Planning the Environment*, 106 Ca. App. 4th, pp. 716, 721-724.) Thus, the appellate court made it clear that the West Creek EIR was insufficient for CEQA purposes.

Pursuant to the Court of Appeal decision, the trial court issued a writ of mandate ordering the County to void its certification of the West Creek EIR and to revise and recirculate the EIR's analysis related to water supply and demand, in compliance with CEQA and the Court of Appeal's decision. (*Santa Clarita Organization for Planning the Environment* v. *County of Los Angeles*, No. 1043805, Santa Barbara County Superior Ct., Judgment Granting Peremptory Writ of Mandate, filed June 30, 2003, at 3.)

In response to the directions of the Court of Appeal and the trial court, the County prepared the West Creek Additional Analysis, comprised of Volumes I through VIII and a two-volume Supplement (Additional Analysis). The first step was the preparation of Volumes I and II (December 2003), the draft Additional

Analysis. Following a review and public comment period on the West Creek draft Additional Analysis, county staff provided for preparation of written responses for further public review, Volumes III and IV (April 2004) of the Additional Analysis.

On May 12, 2004, the County Regional Planning Commission (Planning Commission) continued the West Creek matter due to discovery on the West Creek project site of the western spadefoot toad, a Species of Concern that had been identified in the original West Creek EIR as having a high potential for being present on the site. At the direction of County staff, a *Western Spadefoot Toad Analysis*, Volume V (June 2004), was prepared as a component of the draft Additional Analysis. This augmented environmental analysis was circulated for review and public comment, responses were then prepared and a public hearing held before the Planning Commission.

The next step was for County staff to direct completion of Volume VI (September 2004) of the Additional Analysis, consisting of all written and oral comments received on the western spadefoot toad analysis, responses to those comments, revised Additional Analysis pages amended in response to comments, and additional documents included as appendices. During its public hearing held September 15, 2004, the Planning Commission recommended that the County Board of Supervisors recertify the West Creek EIR as revised by the Additional Analysis (Revised EIR) as adequate under CEQA, and reinstate the several Project Approvals that had been suspended pending the County's certification of a revised West Creek EIR.

The County Board of Supervisors held a public hearing on January 25, 2005, to accept oral and written comments on the Additional Analysis and the proposed Project Approvals and thereafter called for preparation of responses to comments on the revised environmental documentation and closed the hearing with respect to the receipt of such comments. In preparation for a further public hearing to consider the revised EIR and the Project Approvals, County staff provided for the preparation of Additional Analysis, Volume VII (March 2005), which includes comments received prior to and during the January 25 hearing, responses to those comments, and other relevant documents.

On March 22, 2005, the Board of Supervisors held a second public hearing regarding the West Creek revised environmental documentation, including the recently completed Volume VII, and the Project Approvals. On that occasion, the Board of Supervisors closed the public hearing on the West Creek project, recertified the West Creek Revised EIR, as revised by the Additional Analysis, and adopted environmental findings, a Statement of Overriding Considerations, and a Mitigation Monitoring Plan. Revised text and tables to the EIR, with revisions indicated by strikeouts and underlining, were compiled in the Additional Analysis, Volume VIII (April 2005).

Meanwhile, also in April 2005, Valencia reported that it had detected and confirmed the presence of perchlorate at levels ranging between 9.8 and 11 micrograms per liter (ug/l) in its Well Q2, exceeding the State Department of Health Services (DHS) "notification level" for perchlorate of 6 ug/l. Valencia promptly advised the County of this event, removed Well Q2 from service, and undertook an expedited effort to permit and install wellhead treatment, with the expectation of returning the well to public utility service before the end of 2005.

As a consequence of this detection of perchlorate in an additional operating well, the County had a supplement (Supplement) to the West Creek Revised EIR prepared. The purpose of the Supplement was to document the

County's determinations regarding the detection of perchlorate in Valencia's Well Q2. The analysis contained in the Supplement ultimately concluded that the detection did not constitute significant new information or otherwise require recirculation of the Revised EIR, and that, even after this detection, there are sufficient water supplies to serve both West Creek and cumulative development. As the Supplement explained, the detection of perchlorate contamination in this well was not unexpected based on prior studies conducted of the existing contaminated wells. The Supplement further explained that Valencia's response plan was already underway; it involved the installation of wellhead treatment expected to be on-line by the end of 2005; and, it would use ion exchange technology, which DHS has identified as "best available technology" for perchlorate removal, and is currently in use, with DHS approval, in various Southern California locations.

Volume I of the Supplement was released for review and comment in May 2005. The review and comment period for the Supplement concluded on July 5, 2005. County staff prepared responses to comments received and compiled Volume II of the Supplement, including written comments and staff responses, in July 2005. The eight volumes of the West Creek Final Additional Analysis (2003-05) plus the two volumes of the Supplement (2005) serve as the CEQA document required to meet the trial court's direction to reevaluate water supply and demand issues associated with the West Creek project.

The Board of Supervisors held a public hearing on the Revised EIR (including the Additional Analysis with the Supplement) on July 26, 2005. After the close of this final public hearing, the Board recertified the Revised EIR and adopted a revised and updated Findings of Fact and Statement of Overriding

Considerations Regarding the West Creek Project, including an unchanged Mitigation Monitoring Plan.

On January 6, 2006, Santa Barbara County Superior Court, the trial court responsible for reviewing the County's actions in the West Creek matter, issued an Order After Hearing, finding that the revised West Creek EIR and the County's review process were legally sufficient. The trial court held:

> This court finds the Revised EIR does comply with CEQA, and includes accurate availability, reliability supply estimates for State Water Project Water in wet, average and dry years based upon estimates from the DWR, contains revised and re-assessed analysis for water supply and demand, makes clear that SWP entitlements are not equivalent to actual deliveries of water. The court finds that adequate detailed response has been prepared for public comments on the revised EIR. Petitioner's Request to expand the injunction will be denied. (*Santa Clarita Organization* v. *County of Los Angeles*. Order After Hearing, page 2 of 14, filed January 6, 2006, Superior Court of California, County of Santa Barbara, Case Number 1043805.)

Response of Sierra Club

In its August 12, 2005 response (Response) opposing Valencia's motion, Sierra Club raises substantive issues that have been fully addressed in prior Commission decisions or in the additional CEQA review recently certified by the lead agency. Sierra Club's assertions are addressed below.

A. There is No Need for the Commission to Duplicate the County's CEQA Review

Sierra Club claims "substantial new information" regarding the perchlorate issue. (Response, at 2.) This alleged new information was exhaustively addressed in the ten volumes of Additional Analysis augmenting the West Creek EIR and was taken into account in the County's reinstatement of the various permits and approvals for the West Creek project. We find no need for the Commission to duplicate the County's review.

B. The Findings and Conclusions of D.01-11-048 Are Valid

Sierra Club asserts that some of the findings and conclusions of D.01-11-048 related to perchlorate contamination "have now proved to be inaccurate." Specifically, Sierra Club challenges Finding of Fact 32 and Conclusions of Law 5 and 8. (Response, at 2-3.) We find no merit to these challenges.

Finding of Fact 32 in D.01-11-048 is quoted in the Response, at 2, and basically states that it is reasonable to anticipate that the water purveyors will effectively remediate the perchlorate problem in a timely manner so as to preserve their ability to rely on the Saugus Formation as a dry-year supply firming resource. According to Valencia, remediation efforts are on track consistent with the Commission's expectations as evidenced by Finding of Fact 32. Work to clean up perchlorate contamination on the Whittaker-Bermite industrial site was in progress. Valencia is implementing wellhead treatment at its Well Q2 and expected that system to be in place and operating later in 2005. Castaic Lake Water Agency (CLWA) has a containment program in progress and is on schedule for implementing wellhead treatment at two Saugus Formation wells by mid-2006. In short, these developments bear out the accuracy of the Commission's Finding of Fact 32 in D.01-11-048.

Conclusion of Law 5 in D.01-11-048 stated that "[t]he range of supplies the WMP projects as available from the Alluvial Aquifer and the Saugus formation is reasonable." Sierra Club alleges that a Stetson Engineers report disputes the adequacy of prior reports that established the availability of firming supply from the Saugus Formation. Reviewing the excerpt from the Stetson Engineers report that is attached to the Response shows, however, that the Stetson Engineers report does nothing of the sort. That report refers to a "2001 Slade report" (which was received into evidence in this WMP proceeding) as having estimated that "the Saugus Formation can be operated on a long-term average basis in the range of 7,500 to 15,000 AFY" and then concludes the excerpted section by estimating that, with additional well capacity, pumping from the Saugus Formation could range up to 25,000 acre feet per year (AFY) in dry years, but that water quality impacts of increasing such pumping to substantially above 15,000 AFY have not been extensively studied. (Exhibit 6 to Response.) This conclusion does not dispute the adequacy of the 2001 Slade report.

Finally, Conclusion of Law 8 in D.01-11-048 stated that "[t]he WMP's estimate of recycled water supply is reasonable." Sierra Club alleges this conclusion has proven inaccurate, because the recycled water amount currently used in the West Creek documents is 1,700 acre feet (AF) while the WMP used 17,000 AF. Here Sierra Club is mixing apples and oranges—or, more specifically, existing supply and future planned supply. The West Creek Additional Analysis presents the facts in its Summary of Water Supply and Demand (Volume I of II, December 2003, Section 2.0). Table 2.0-3 includes 1,700 AFY of Recycled Water in a mix of "Existing Water Supply" that more than meets existing plus project demand in a critical dry year. Table 2.0-4 retains that 1,700 AFY of Recycled Water as part of Existing Water Supply and expands that supply to include 17,000 AFY of Recycled Water under the heading of "Future Planned Water Supply Programs" as part of its supply and demand assessment for Year 2020. Thus, rather than contradicting the Commission's Conclusion of Law 8 of D.01-11-048, the West Creek Additional Analysis confirms the accuracy of that conclusion. In short, we find no basis for Sierra Club's assertions regarding the adequacy of Finding of Fact 32 and Conclusions of Law 5 and 8 of D.01-11-048.

C. Castaic Lake Water Agency's Acquisition of State Water Entitlements Provides No Basis to Deny Valencia's Motion

CLWA supplies SWP water to Valencia and other retailers in the area. Sierra Club makes an issue out of CLWA's alleged failure to abide by the "Monterey Settlement Agreement" in its acquisition of a 41,000 AFY entitlement to SWP supply. (Response, at 3.) While these parties may be pursuing litigation with respect to the revised EIR that CLWA completed and certified with respect to its acquisition of additional SWP supply, we believe the EIR for that supply must be presumed adequate for current planning processes. (See, CEQA Guidelines, 14 Cal. Code Regs., § 15231.) Moreover, in denying a motion for an order to decertify the revised EIR, the trial court held:

> This court finds that the uncertainties involving the 41,000 afy transfer were adequately disclosed in the revised EIR, and substantial evidence supports the County's conclusion that it could be relied upon for planning purposes, notwithstanding the pending DWR environmental review and the fact that it is not among those transfers listed as immune from challenge in the PCL Settlement Agreement. (*Santa Clarita Organization* v. *County of Los Angeles*. Order After Hearing, page 2 of 14, filed January 6, 2006, Superior Court of California, County of Santa Barbara, Case Number 1043805.)

Thus, we reject Sierra Club's argument that CLWA's 41,000 AFY entitlement of SWP supply cannot be used for planning purposes simply because there is pending litigation on CLWA's EIR.

D. The Commission Should Not Defer Implementing D.01-11-048

Until Further Judicial Proceedings Conclude

By letter dated February 6, 2006, SCOPE informed the Commission that it had appealed the trial court's Order After Hearing issued on January 6, 2006, finding that the County's review process was legally sufficient. Therefore, SCOPE urges the Commission to wait for the outcome of the appeal before lifting the stay of D.01-11-048 related to the West Creek project.

Valencia replies that the County, the lead agency for the West Creek project, has treated the revised final EIR as sufficient and has granted grading, construction, and other permits to allow the project to proceed. The developer has commenced grading and the first sales of land within the development are expected to close in July 2006, with homes planned for occupancy by April 2007. Valencia argues that as the Commission considers whether to lift its stay of D.01-11-048, CEQA Guidelines Section 15231 requires the Commission to assume that the County's revised final EIR complies with CEQA, and the conclusive presumption of Section 15231 applies in this case. Therefore Valencia believes that the Commission can and should lift the stay of D.01-11-048 imposed by D.03-10-063 regarding the Commission's approval of the West Creek EIR.

Discussion

The Commission's CEQA role in this matter is that of a Responsible Agency pursuant to Public Resources Code Section 21069 and CEQA Guidelines Section(s) 15096 *et seq*. The Commission CEQA staff of the Energy Division (Staff) independently reviewed the Supplement to the EIR and the Final Additional Analysis and determined that the recertified EIR and its Supplement identify and address all the potential significant impacts – including the water demand for the West Creek project, and the detection of perchlorate in one of

Valencia's Wells. Also, the County approved the EIR with a Statement of Overriding Considerations. Staff concludes that the Supplement to the EIR and the Final Additional Analysis dated July 2005 are legally sufficient for Valencia to be allowed to serve the West Creek project.

We deny SCOPE's request that we wait for the outcome of its (second) appeal of the trial court's order. CEQA Guidelines Sections 15231, 15233 and Pub. Res. Code § 21167.3, when read in conjunction with *City of Redding*[2] and other legal authority *require* responsible agencies, which we are in this case, to move forward on its role in the process regardless of the appeal. Furthermore, there is no court injunction in effect in connection with SCOPE's appeal. The County of Los Angeles, lead agency for the West Creek project, has treated the revised final EIR as sufficient and, notwithstanding the legal challenges of SCOPE and Friends, has granted grading, construction, and other permits to allow the project to proceed. Thus, we find no basis for continuation of the stay on D.01-11-048.

In summary, we find no merit to the claims of Sierra Club related to D.01-11-048. As the record demonstrates, the environmental concerns related to this project have been exhaustively reviewed. We conclude that the time has come for the Commission to allow Valencia to serve the West Creek project within the scope of its approved WMP and to close this six-year-old proceeding.

---

Comments on Draft Decision

The draft decision of the Administrative Law Judge (ALJ) in this matter was mailed to the parties in accordance with Pub. Util. Code § 311(g)(1) and Rule 77.7 of the Commission's Rules of Practice and Procedure. Opening comments on the draft decision were filed by Valencia and Sierra Club on August 10, 2006. Reply comments were filed by Valencia on August 15, 2006.

Sierra Club repeats the same arguments it made previously, which were addressed in the draft decision. None of Sierra Club's arguments have merit. Rather than summarily dismiss Sierra Club's arguments, we will go over the issues one more time, with the latest update.

The issue at hand is whether to remove a stay from a decision (D.01-11-048) the Commission adopted nearly five years ago, based on the completion of additional CEQA review by the lead agency and that lead agency's reinstatement of approvals for the West Creek project for which the Commission's decision authorized Valencia to provide public utility water service. All substantive issues to which Sierra Club alludes have been fully addressed in prior Commission decisions or in the additional CEQA review recently certified by the lead agency.

A. There Has Been No Significant Change of Circumstances Since Recertification of the West Creek EIR

Sierra Club asserts that further environmental impact review pursuant to the CEQA is required because "circumstances have substantially changed" since the EIR for the West Creek project was recertified by the County of Los Angeles in July 2005. Sierra Club refers to the perchlorate containment program.

Valencia responds, that it is no surprise that "ground monitoring" of the Whittaker-Bermite site has revealed very high levels of perchlorate. That site, formerly used for the manufacture of rocket fuel, has been identified for many years as the probable source of perchlorate contamination in the Santa Clarita area. Valencia points out that the fact of contamination on the Whittaker-Bermite site is not a significant change of circumstances, and that is discussed in D.01-11-048.

Further, Valencia responds that the detection of perchlorate in a new well operated by Newhall County Water District is not "a further indication of the continued spread of the ammonium perchlorate pollution in a westerly direction. As indicated by the news article Sierra Club attached as Exhibit 1 to its comments, this perchlorate detection was at a "minimal" level ("from undetectable to up to 1.9 parts per billion"), well below the state-recommended "safe drinking water" limit of 6 parts per billion, in a Saugus Aquifer well within 1,000 feet of another Saugus well that has been capped due to perchlorate contamination since 1998. Valencia contends that contrary to Sierra Club's assertions, such a "minimal" detection does not indicate anything about the spread of perchlorate and is not a significant change of circumstances. Accordingly, we reject Sierra Club's argument. The events to which Sierra Club refer do not constitute significant changes in the context of the water supply analysis in the West Creek EIR.

B. Sierra Club Misstates the Facts Regarding CLWA's Containment Program

Sierra Club asserts that the draft decision "is factually incorrect" in its description of the perchlorate containment program that CLWA now has in progress. Valencia responds that contrary to Sierra Club's claim that "CLWA does not have a containment program in progress" and has no funding available for clean-up or treatment facilities, CLWA's containment program is well under way and ample funding is in escrow.

According to Valencia, CLWA developed an Interim Remedial Action Plan to address groundwater contamination by perchlorate in conformance with Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) and that action plan was approved by the California Department of Toxic Substances Control in January 2006. CLWA also completed CEQA review of its remedial action plan in the same time frame, and neither the action plan nor the CEQA review has been subject to any judicial challenge. The final design for treatment facilities is nearly complete; the groundbreaking ceremony is set to occur in August 2006; the construction work is scheduled to be put out for bid in the fall of 2006, with construction to be completed and operation to commence in 2007. Funding to cover all remedial work has been secured by a settlement between Whittaker-Bermite and its insurance carriers, with many millions of dollars currently held in escrow. A settlement of claims by CLWA and other water purveyors is pending, and is expected to result in the assignment of the escrowed funds for implementation of CLWA's Interim Remedial Action Plan.

Valencia states that in short, the draft decision would be correct in stating that CLWA has a perchlorate containment program in progress and is in the process of implementing wellhead treatment at two Saugus Formation wells. With the minor changes of wording suggested in its opening comments, Valencia submits that the draft decision will accurately describe the current status of perchlorate remediation efforts of concern to Valencia and its customers.

In summary, we find no merit in Sierra Club's argument regarding the lack of progress in CLWA's perchlorate containment program. We will make the wording changes to the draft decision as suggested by Valencia to reflect the status update.

C. Sierra Club's Challenges to Various Elements of the Water Supply Analysis in the West Creek EIR Are Irrelevant to the Commission's Obligation as a Responsible Agency to Presume the EIR Adequate for Current Planning Purposes

Sierra Club repeats its argument that Valencia is improperly relying on several sources of water supply, including CLWA's acquisition of a 41,000 AFY entitlement to State Water Project (SWP) supply, the use of "polluted water" from the Saugus Aquifer, and the projection of recycled water supply in excess of the amount currently available. Sierra Club alleges that, "as a matter of law," Valencia may not rely on these water sources in its water supply planning.

Valencia responds that the problem with Sierra Club's continual renewal of its challenges to Valencia's consideration of particular water supply sources is that the claims are taken out of context. The Water Code provisions on which Sierra Club appears to rely apply to the consideration of water supply for land use projects, not to the long-range water supply projections entailed in a Water Management Program. The particular land use project at issue in the present case is the West Creek project, for which Los Angeles County has certified an EIR in July 2005. Commission staff has reviewed that EIR and that review is reflected in the draft decision.

We note that Sierra Club made similar claims in its response to Valencia's motion, filed last August. At that time, Sierra Club tried to make an issue out of CLWA's alleged failure to abide by the "Monterey Settlement Agreement" in its acquisition of a 41,000 AFY entitlement to SWP supply. The draft decision notes that regardless of litigation with respect to the revised EIR that CLWA completed and certified with respect to its acquisition of additional SWP supply, the EIR for that supply must be presumed adequate for current planning processes, citing the CEQA Guidelines, 14 Cal. Code Regs., § 15231. On this basis, the draft decision rejects Sierra Club's claim that CLWA's 41,000 entitlement cannot be taken into account for planning purposes simply because litigation is pending on CLWA's EIR. We agree with that conclusion.

D. There Was No Procedural Impropriety in the Commission Employing Its Expert Environmental Review Staff to Review the Recertified West Creek EIR

Sierra Club claims it was "procedurally incorrect" for the Commission to have its Energy Division staff review the supplemental West Creek EIR materials and assess their adequacy in addressing potential impacts. We remind Sierra Club that the issue before the Commission is the adequacy of the CEQA analysis done by Los Angeles County on the recertification of the West Creek EIR. Sierra Club apparently is unaware of the long experience of the Environmental Review Branch of the Energy Division in addressing CEQA compliance issues relating to all classes of public utilities subject to the Commission's jurisdiction.

Review of the recertification of the West Creek EIR was done by the Commission's CEQA staff. The CEQA staff is located in the Energy Division as a purely administrative means of co-locating all of the Commission's CEQA technical experts, who work across all industries regulated by the Commission. The Commission derives a number of benefits from the efficiencies and cross-expertise associated with this institutional arrangement. Indeed, having the same technical staff work on all CEQA compliance issues across industries serves to ensure consistency in the Commission's application of CEQA across those industries. Sierra Club's allegation of improper procedure is without merit.

E. Any Stay of Trial Court Proceedings Has No Bearing on the Commission's Obligation to Presume the West Creek EIR Adequate for Current Planning Purposes

Sierra Club relies on Code of Civil Procedure (CCP) § 916, which addresses trial court proceedings subject to appeal, to assert that the Commission should not apply the recertified West Creek EIR until the Court of Appeal has ruled on the pending appeal of its sufficiency. This claim is without merit. The CEQA Guidelines, not the CCP, govern the Commission's conduct in this context. As discussed in the draft decision, the CEQA Guidelines direct the Commission to presume a certified EIR adequate for current planning processes, even if subject to a pending appeal. (See, CEQA Guidelines, 14 Cal. Code Regs., § 15231.)

In summary, we will adopt the draft decision with a few language changes to reflect the current status of the perchlorate containment program.

Assignment of Proceeding

Geoffrey F. Brown is the Assigned Commissioner and Bertram D. Patrick is the assigned ALJ in this proceeding.

Findings of Fact

1. The Commission acting on its own motion in D.03-10-063, imposed a stay on D.01-11-048 insofar as it approved the West Creek EIR.

2. The Commission directed that the stay of D.01-11-048 would remain in effect pending recertification of the West Creek EIR by the lead agency, the County, and resubmission of the West Creek EIR to the Commission.

3. On July 26, 2005, the County recertified the Revised EIR for the West Creek project.

4. The County of Los Angeles is the Lead Agency for the proposed project pursuant to CEQA.

5. The Commission is a Responsible Agency for the proposed project pursuant to CEQA.

6. The Board of Supervisors of the County of Los Angeles voted on July 26, 2005, to approve and recertify the West Creek Final Additional Analysis and Supplement, and adopted a revised and updated Findings of Fact and prepared a Statement of Overriding Considerations, including an unchanged Mitigation Monitoring Plan.

7. Staff has independently reviewed the application by Valencia Water Company, including the Environmental Impact Report for the West Creek project, as revised by the West Creek Final Additional Analysis and Supplement.

8. Staff has reviewed the Findings of Fact and Statement of Overriding Considerations adopted by the Board of Supervisors of the County of Los Angeles for the West Creek Project.

9. The Commission has considered the revised West Creek Final Additional Analysis and Supplement prepared by Los Angeles County in its decision making process in accordance with the CEQA Guidelines Section 15096 *et seq*.

Conclusions of Law

1. The West Creek Final Additional Analysis and Supplement developed by the County of Los Angeles is adequate for this Commission's independent decision making purposes pursuant to CEQA Guidelines Section 15096 *et seq.*

2. The Commission has independently considered the County of Los Angeles' West Creek Final Additional Analysis and Supplement in its decision making process in accordance with the CEQA Guidelines Section 15096 *et seq.*

3. With the recertification of the West Creek EIR, the conditions stated in D.03-10-063 have been met; therefore, the stay of D.01-11-048 should be lifted and Valencia authorized to serve the West Creek project.

O R D E R

IT IS ORDERED that:

1. The July 28, 2005 motion of Valencia Water Company (Valencia) to reopen this proceeding and terminate the stay of Decision (D.) 01-11-048, is granted.

2. The stay of D.01-11-048 imposed by D.03-10-063 is lifted and Valencia is authorized to expand its service area to serve the West Creek project consistent with its approved Water Management Plan and the recertified Revised West Creek Environmental Impact Report.

3. Application 99-12-025 is closed.

This order is effective today.

Dated August 24, 2006, at San Francisco, California.

2003 POINT OF DELIVERY AGREEMENT AMONG THE DEPARTMENT OF WATER RESOURCES OF THE STATE OF CALIFORNIA CASTAIC LAKE WATER AGENCY AND KERN COUNTY WATER AGENCY

SWPAO #03060

SWPAO #03060

State of California
The Resources Agency
DEPARTMENT OF WATER RESOURCES

2003 POINT OF DELIVERY AGREEMENT AMONG
THE DEPARTMENT OF WATER RESOURCES OF THE STATE OF CALIFORNIA
CASTAIC LAKE WATER AGENCY
AND
KERN COUNTY WATER AGENCY

THIS AGREEMENT is made this 13th day of February, 2004, pursuant to the provisions of the California Water Resources Development Bond Act and other applicable laws of the State of California, among the State of California, acting by and through its Department of Water Resources, herein referred to as the "DEPARTMENT," the Kern County Water Agency, herein referred to as the "AGENCY," a political subdivision of the State of California created by an Act of the California State Legislature (Statutes 1961, Chapter 1003 or as amended), and the Castaic Lake Water Agency, herein referred to as "CASTAIC LAKE," a political subdivision of the State of California created by an Act of the California State Legislature (Statues 1962, Chapter 103 or as amended).

RECITALS

A. CASTAIC LAKE and Semitropic Water Storage District, herein referred to as "SEMITROPIC," a Member Unit of the AGENCY, entered into an agreement dated January 15, 2004. Such agreement, herein referred to as "Castaic Lake/Semitropic Program Agreement" provides for the storage and recovery rights on an interim basis for the Semitropic Water Banking and Exchange Program which is owned, operated, and maintained by SEMITROPIC.

B. The DEPARTMENT, AGENCY, and SEMITROPIC have entered into an agreement entitled "Agreement Among Department of Water Resources, State of California, Kern County Water Agency and Semitropic Water Storage District for Introduction of Local Water into the California Aqueduct," executed on May 2, 1995 and subsequently amended. Such agreement, herein referred to as the "Semitropic Turn-in Agreement," contains terms and conditions governing the introduction of Local Water into the California Aqueduct. Under certain circumstances, water stored on behalf of CASTAIC LAKE could be recovered by SEMITROPIC and introduced into the California Aqueduct under the terms of the Semitropic Turn-in Agreement.

C. Pursuant to Article 15(a) of CASTAIC LAKE'S long-term Water Supply Contract with the DEPARTMENT, the DEPARTMENT hereby finds that the delivery and temporary storage of water outside CASTAIC LAKE'S service area under this Agreement and the Castaic Lake/Semitropic Program Agreement will not materially impair CASTAIC LAKE'S capacity to make payments to the DEPARTMENT.

D. This Agreement applies to CASTAIC LAKE'S 2003 approved Table A amount.

E. CASTAIC LAKE has not elected to sell SWP water during the year 2003 pursuant to CASTAIC LAKE'S Water Supply Contract with the DEPARTMENT.

F. The purpose of this Agreement is to set forth provisions governing the delivery of up to 35,000 acre-feet of CASTAIC LAKE'S 2003 approved Table A amount for storage in the Semitropic Water Banking and Exchange Program, and for the future return of such water by exchange of a like amount of the AGENCY'S Table A water, or recovery by direct pumpback of CASTAIC LAKE'S stored water into the California Aqueduct from the Semitropic Water Banking and Exchange Program. CASTAIC LAKE has requested to deliver a portion of its 2003 SWP carryover supplies in the first three months of 2004. This Agreement is to facilitate Castaic Lake's water management to store water outside its service area due to unusual hydrology and a late Table A allocation approval in 2003. This agreement is unique and shall not be considered a precedent for any future agreements.

G. Consistent with the California Environmental Quality Act, CASTAIC LAKE, as the lead agency prepared, and on December 3, 2003, filed with the Office of Planning and Research, an *Initial Study and Negative Declaration for the Castaic Lake Water Agency 2003 Groundwater Banking Project.* CASTAIC LAKE'S Board of Directors, at its public hearing, adopted findings and a Negative Declaration for the proposed project on January 14, 2004.

H. CASTAIC LAKE intends to have all water stored in SEMITROPIC under this agreement returned within 10 years consistent with the terms of this agreement and the Castaic Lake/Semitropic Program Agreement.

I. For any future single or multi-year agreements to store water outside its service area, CASTAIC LAKE shall complete additional and more comprehensive environmental documentation.

AGREEMENT

The DEPARTMENT approves delivery of up to 35,000 acre-feet of CASTAIC LAKE'S 2003 approved SWP water supplies for storage in the Semitropic Water Banking and Exchange Program within the AGENCY'S service area, and for the future return of such water by exchange of a like amount of the AGENCY'S approved Table A water or recovery by direct pumpback under the following terms and conditions:

1. TERM

   Upon execution by all parties, this Agreement shall be effective as of October 1, 2003, and shall provide for the delivery of up to 35,000 acre-feet of CASTAIC LAKE'S 2003 approved SWP water supplies to the Semitropic Water Banking and Exchange Program at reach 10A of the California Aqueduct from October 1, 2003 through March 31, 2004. This Agreement shall terminate with the delivery of all return water to CASTAIC LAKE under this Agreement or by March 31, 2014, whichever comes first, unless the Castaic Lake/Semitropic Program Agreement is fully terminated. In that event, this Agreement will be terminated on the same date as the termination of the Castaic Lake/Semitropic Program Agreement.

2. USE OF STORED WATER

   a. SWP water delivered by the DEPARTMENT to the AGENCY on behalf of CASTAIC LAKE under this Agreement will not be sold to or by the AGENCY but will be temporarily stored for CASTAIC LAKE and later recovered by direct pumpback or exchanged for a like amount of the

AGENCY'S approved Table A water to be used in CASTAIC LAKE'S service area. All water stored pursuant to this agreement shall be returned to CASTAIC LAKE by March 31, 2014. The specific provisions for storage and return of CASTAIC LAKE'S water in the Semitropic Water Banking and Exchange Program are governed by the Castaic Lake/Semitropic Program Agreement. As provided in said agreement, 90 percent of CASTAIC LAKE'S water delivered to SEMITROPIC will be returned to CASTAIC LAKE for use in CASTAIC LAKE'S service area within 10 years, unless CASTAIC LAKE and the AGENCY agree that the actual losses are different than the assumed 10 percent as therein provided.

b. In the event return water is delivered to CASTAIC LAKE by exchange, the parties acknowledge that the AGENCY shall be entitled to an amount equivalent to 90% of CASTAIC LAKE'S water previously stored in the Semitropic Water Banking and Exchange Program.

3. USE OF CALIFORNIA AQUEDUCT CAPACITY FOR STORED AND RETURN WATER

Conveyance of the storage and return water in the California Aqueduct shall be in accordance with a schedule approved by the DEPARTMENT. CASTAIC LAKE'S Water Supply Contract with the DEPARTMENT shall govern priority of delivery for return water. CASTAIC LAKE shall be responsible for any demonstrable adverse impacts that may result from deliveries under this Agreement as determined by the DEPARTMENT. To the extent CASTAIC LAKE increases its requests for Table A water as a result of this Agreement, such increases shall not be considered an adverse impact.

4. DELIVERY SCHEDULES FOR STORED/RETURN WATER

a. <u>State Approval of Delivery Schedules</u>: In coordination with and upon approval of the AGENCY, CASTAIC LAKE shall be responsible for scheduling delivery of CASTAIC LAKE'S water with the DEPARTMENT. All water delivery schedules and revisions shall be in accordance with Article 12 of CASTAIC LAKE'S Water Supply Contract with the DEPARTMENT. The DEPARTMENT'S approval of the schedules is dependent upon the times and amounts of the scheduled water and the overall delivery capability of the SWP. Water delivered to CASTAIC LAKE or the AGENCY shall be scheduled when the sum of deliveries scheduled to CASTAIC LAKE or the AGENCY under this agreement, plus the scheduled approved annual Table A deliveries, plus deliveries pursuant to any other agreements, do not exceed the quantities on which the Proportionate Use-of-Facilities factors are based pursuant to CASTAIC LAKE'S and the AGENCY'S Water Supply Contracts with the DEPARTMENT, unless the DEPARTMENT determines that the deliveries will not adversely impact Table A deliveries to SWP contractors or adversely impact SWP operations or facilities. The DEPARTMENT shall not be obligated to convey water for storage or return water at times when such delivery would adversely impact SWP operations or facilities, other SWP contractors' water deliveries or costs, or delivery of Table A water or other water supplies to the AGENCY.

b. Delivery Schedules for Stored Water: As part of coordinating delivery schedules with the AGENCY, CASTAIC LAKE shall submit a delivery schedule for delivery of CASTAIC LAKE'S water into storage, which shall include but not necessarily be limited to amounts, times, rates of delivery, and points of delivery, to the AGENCY for review and approval. The AGENCY shall review the proposed schedule with CASTAIC LAKE and as promptly as possible shall inform CASTAIC LAKE of its decision to either approve, propose modifications, or withhold approval. The AGENCY agrees that it shall not arbitrarily withhold approval or propose unreasonable modifications. The AGENCY may deny approval of, or propose modification to, CASTAIC LAKE'S delivery schedule under this Agreement, if on the basis of a with and without analysis, the AGENCY determines that such deliveries would adversely impact the AGENCY'S water management activities, finances, water supply or operations, and CASTAIC LAKE does not agree to mitigate for such impacts. The base case (without analysis) shall be those conditions estimated to occur in the absence of the CASTAIC LAKE/Semitropic Program Agreement. Upon receipt of the AGENCY'S approval, CASTAIC LAKE shall submit the delivery schedule to the DEPARTMENT for approval. The DEPARTMENT shall not approve any CASTAIC LAKE schedule that has not been approved by the AGENCY.

c. Delivery Schedules for Return Water: CASTAIC LAKE shall, as soon as possible, submit a schedule to the AGENCY specifying the quantity of CASTAIC LAKE'S previously stored water to be returned by recovery and direct pumpback or by exchange of a portion of the AGENCY'S approved Table A water. If delivered by exchange, the parties shall provide copies of all necessary agreements. Said schedules shall specify the amount, month, and year when said return water was previously stored. The AGENCY may propose modifications to the proposed schedule for the return of CASTAIC LAKE'S previously stored water if, on the basis of a with and without analysis, the AGENCY determines that such scheduled deliveries will adversely impact the AGENCY'S finances, water supply or operations, and CASTAIC LAKE does not agree to mitigate for such impacts. The AGENCY agrees that it shall not propose unreasonable modifications. The base case (without analysis) shall be those conditions estimated to occur in the absence of the CASTAIC LAKE/ Semitropic Program Agreement.

5. APPROVED TABLE A WATER

Water returned to CASTAIC LAKE under this Point of Delivery Agreement shall not be considered by the DEPARTMENT in the determination of approved Table A water under Article 18 or allocation of other SWP water to CASTAIC LAKE under CASTAIC LAKE'S Water Supply Contract with the DEPARTMENT.

6. RETURN WATER DELIVERED INTO AQUEDUCT

Water returned by recovery and direct pumpback to the California Aqueduct from the Semitropic Water Banking and Exchange Program on behalf of CASTAIC

LAKE shall meet the terms of the Semitropic Turn-in Agreement.

7. STORED/RETURN WATER RECORDS

CASTAIC LAKE shall certify to the DEPARTMENT'S State Water Project Analysis Office by January 31 of each year the following information for the previous calendar year:

a. The quantity of water delivered and stored under this Agreement.

b. The quantity of water stored under this Agreement that will be available for return to CASTAIC LAKE.

c. The actual losses of stored water, if CASTAIC LAKE and the AGENCY agree that actual losses are different than the 10 percent assumed in the CASTAIC LAKE/Semitropic Program Agreement.

d. The quantity of water returned to CASTAIC LAKE pursuant to this agreement.

The DEPARTMENT will maintain monthly records accounting for the delivery of CASTAIC LAKE'S SWP water supplies delivered pursuant to this Agreement for storage in the Semitropic Water Banking and Exchange Program and the future return of water delivered from the AGENCY to CASTAIC LAKE.

8. CHARGES

a. <u>Water Delivered to Storage</u>:

CASTAIC LAKE shall pay the DEPARTMENT the Variable Operation, Maintenance, Power and Replacement Component of the Transportation Charge and Off-Aqueduct Power Facility Costs for power resources incurred in the transportation of such water to SEMITROPIC turnouts in

Reach 10A of the California Aqueduct.

b. Return Water Delivered:

(1) When the AGENCY returns stored water by recovery and direct pumpback to Reach 10A of the California Aqueduct for delivery to CASTAIC LAKE'S service area, CASTAIC LAKE shall pay the DEPARTMENT the Variable Operation, Maintenance, Power and Replacement Component of the Transportation Charge and Off-Aqueduct Power Facility Costs for power resources incurred in the delivery of such water from Reach 10A of the California Aqueduct to CASTAIC LAKE'S turnouts in Reach 30 of the California Aqueduct.

(2) When the AGENCY returns stored water by an exchange of its allocated Table A water, the AGENCY shall be entitled to an amount equivalent to 90 percent of CASTAIC LAKE'S previously stored water and the AGENCY will release a like amount of the AGENCY'S Table A water on behalf of SEMITROPIC at Reach 10A. The AGENCY shall pay the Variable Operation, Maintenance, Power and Replacement Component of the Transportation Charge and Off-Aqueduct Power Facility Costs for power resources incurred as if such water were conveyed to the AGENCY from the Delta to Reach 10A of the California Aqueduct. CASTAIC LAKE shall pay the Variable Operation, Maintenance, Power and Replacement Component of the Transportation Charge

and Off-Aqueduct Power Facility Costs for power resources incurred from Reach 10A to CASTAIC LAKE'S turnout structures in Reach 30.

c. In addition to the charges identified above, CASTAIC LAKE agrees to pay to the DEPARTMENT any additional identified non-power costs that would otherwise be borne by the SWP contractors not signatory to this Agreement or by the DEPARTMENT as a result of the DEPARTMENT providing service under this Agreement.

d. Payment terms shall be in accordance with the AGENCY'S and CASTAIC LAKE'S Water Supply Contracts with the DEPARTMENT.

9. APPROVALS

The delivery of water under this Agreement shall be contingent on and subject to any necessary approvals and shall be governed by the terms and conditions of such approvals and any other applicable legal requirements. CASTAIC LAKE shall be responsible for securing any required approvals, permits or orders. CASTAIC LAKE shall furnish to the DEPARTMENT copies of all approvals acquired for the delivery and storage of water under this Agreement.

10. LIABILITY

a. The DEPARTMENT is only providing water delivery service through the SWP and assumes no liability for the AGENCY'S or CASTAIC LAKE'S water under this Agreement beyond the designated points of delivery.

b. In the event of a claim of liability against the DEPARTMENT or the AGENCY or their officers or their employees, individually or severally, that arises as a result of this Agreement or other related agreements, CASTAIC LAKE shall defend, indemnify, and hold the AGENCY, the DEPARTMENT, and any of their officers or employees harmless from any such claim, except to the extent that such claim arises from the sole negligence or willful misconduct of the AGENCY and/or the DEPARTMENT.

11. NO MODIFICATION OF WATER SUPPLY CONTRACTS

This Agreement shall not be interpreted to modify the terms or conditions of either the Water Supply Contract between the DEPARTMENT and the AGENCY dated November 15, 1963, or the Water Supply Contract between the DEPARTMENT and CASTAIC LAKE dated April 30,1963, as both are amended up to and including the date of this Agreement.

12. CLAIMS DISPUTE

In the event of dispute regarding interpretation or implementation of this Agreement, the Director of the Department of Water Resources and general managers of CASTAIC LAKE and the AGENCY shall endeavor to resolve the dispute by meeting within 30 days after the request of a Party. If the dispute is unresolved, the Parties shall use the services of a mutually acceptable consultant in an effort to resolve the dispute. Parties involved in the dispute shall share the fees and expenses of the consultant equally. If a consultant cannot be agreed upon, or if the consultant's recommendations are not acceptable to the Parties, and unless the Parties otherwise agree, the matter may be resolved by litigation and any Party may at its option pursue any available legal remedy including, but not limited to, injunctive and other equitable relief.

13. ASSIGNMENT OF AGREEMENT

This Agreement shall not be assignable by the AGENCY or CASTAIC LAKE in whole or in part without the written consent of the DEPARTMENT, AGENCY and CASTAIC LAKE.

14. MODIFICATION OF AGREEMENT

No modification of the terms of this Agreement shall be valid unless made in writing and signed by the Parties to this Agreement.

15. SIGNATURE CLAUSE

The signatories represent that they have been appropriately authorized to enter into this Agreement on behalf of the Party for whom they sign.

IN WITNESS WHEREOF, the Parties hereto have entered into this Agreement.

CLWA Resolution Regarding Availability of Recycled Water, Approved May 28, 2003

Approved [illegible]

RESOLUTION NO.

ITEM NO.
6.1 (1)

REGARDING AVAILABILITY OF RECYCLED WATER

WHEREAS, the use of recycled water for non-potable purposes within CLWA and Retailer is of significant benefit to all water users, in that it applies the recycled water to uses that might otherwise use the potable water supplies to be available for more beneficial uses; and

WHEREAS, it is the policy of the State of California to encourage the use of recycled water if it is available for non-potable uses, including, but not limited to, cemeteries, golf courses, parks, highway landscaped areas, and industrial and irrigation uses; and

WHEREAS, the California Legislature has declared that the use of recycled water has proven to be safe from a public health standpoint, and that use of recycled water is a cost-effective, reliable method of helping to meet California's water supply needs; and

WHEREAS, Castaic Lake Water Agency ("Agency" herein) was created under the Castaic Lake Water Agency Law (Cal. Water Code, App. § 103-1 *et seq.*), which authorizes Agency to deliver recycled water; and

WHEREAS, Agency has contracts with Sanitation Districts No. 26 and 32 of Los Angeles County (the "Districts"), dated July 24, 1996 (the "District Agreement"), to purchase reclaimed water ("Recycled Water") from the Valencia Water Reclamation Plant; and

WHEREAS, the State Water Resources Control Board ('State Board" herein) has determined that Recycled Water is of adequate quality for the uses specified in Water Code Section 13550; and

WHEREAS, the State Board has determined that Recycled Water may be furnished for the uses specified in Water Code Section 13550 at reasonable cost to the User, being comparable to or less than the cost of supplying potable domestic water; and

WHEREAS, the State Board has determined that the State Department of Health Services concurs that Recycled Water will not be detrimental to public health; and

WHEREAS, the State Board has determined that the use of Recycled Water for the uses specified in Water Code Section 13550 will not degrade water quality, and has been determined not to be injurious to plant life, fish, and wildlife; and

WHEREAS, the County of Los Angeles has determined that certain areas of lands within the County and within the boundaries of the Agency should use Recycled Water as specified in Water Code Section 13550 as a condition of development; and

WHEREAS, the Agency established its intent to sell recycled water by the adoption of Resolution No. 2180 in 2002 by establishing its water rate for recycled water, on a volume basis, as 80% of the normal retail water distributor rate to an end user of the distributor as that rate may change from time to time and authorized the Agency's General Manager to promulgate management procedure orders in furtherance of the Agency recycled water rate;

NOW, THEREFORE, BE IT HEREBY RESOLVED:

1. The Agency declares that, subject to availability and regulatory requirements and Agency management procedure orders as they exist and are changed from time to time, Recycled Water is available to certain areas defined by the Agency in its sole discretion, within its boundaries subject to the requirement of Water Code Section 13550 et seq., including, but not limited to, the requirement that the cost of supplying Recycled Water is comparable to, or less than, the cost of supplying potable domestic water.
